"Whereas we proclaim that any agreement obtained by force, threat or fraud is neither legally or morally binding, or cannot be interpreted as a settlement of our wage dispute.

"Be it therefore resolved that we demand of the executive board that they refuse to sign the said Sydney agreement in its present form either for eighteen months or any period of time until the said agreement is submitted to the international board for its approval."

The above resolution is a fair sample of the regular output of the Phalen Local, the largest local in Nova Scotia. It seems that a quarrel is on between this local and International Board member Barrett and J. S. Lewis, President. The resolution is a tissue of misrepresentation from beginning to end and no man is better

qualified to see this than President Lewis, who will repudiate it. He will no doubt tell this local that it has failed to carry out his instructions during the strike by refusing to save the collieries from being flooded, and they can now carry out the wishes of the rank and file, who voted for the agreement, and sign up as soon as possible.

As to eviction, etc., this is absolutely a false statement and is without any grounds. If there was intimidation it was on the part of the striking miners, who held up everybody and everything that they thought would interfere with their plans.

The agreement will be signed irrespective of Phalen local. The other locals are tired of all this unnecessary agitation and are in a mood to tell the members of Phalen to mind their own business.

Local Dissatisfaction over Agreement

When the Nova Scotia miners learned that work was to be resumed in the American collieries at the 1920 rates, there were those who began to talk loudly about the bad settlement effected by their leaders. This was further accentuated when it became known that the Alberta miners had agreed to return to work on a fifteen per cent. reduction pending the settlement in the United States. Without taking time to think the matter over, a few malcontents began to claim that they were badly treated. International Board Member Barrett lent color to their belief when on returning from the United States he criticised the making of any agreement under the 1920 rates. Workingmen can be excused for not being able at all times to think logically, as they have not always a clear view of all sides of their case; but when a leading officer attempts to mislead them, he is not doing it in the best interest of the industry or of the men he pretends to lead. Having on more than one occasion been forced to defend his action and give a reason for the faith that was in him, Mr. Barrett has stated again and again that during the war period the miners of Nova Scotia had received much larger increases than the American miners. This being so, why does he now make comparisons that places them in an unfavorable light? Is it because of his interest in the miners or because he sees an opportunity again to become popular by criticising others and stirring up strife? No one knows better than he does that the Nova Scotian and American miners are going back on the same basis. The McKinnon Award came into force at the collieries in 1920. The American miners received an increase in the same year, but none since then. But in 1921 the miners of Nova Scotia received a further increase of wages. The parties to the agreement recognized this and when the 1920 wage rates were accepted, where was the injustice to the miner workers of Nova Scotia? It does seem that if the mine workers are to work contentedly it can only be when they know that they have kept pace with their fellow workmen in the United States, with whom they have linked up to advance their moral and material interests. What Mr. Barrett "would work the miners to" may not be apparent to all; but even the casual observer can see mischief afoot in his recent criticisms.

Miners now Well Paid

With steady employment the miners of Nova Scotia at present rates will be able to make fair wages. This is freely admitted and will tend to greater harmony. But if it should happen that we may not be able to fully wrest the Quebec market from the Americans and push our coal further west, then we may find ourselves stalemated and the whole industry will suffer from the effect of arrested growth. Indeed it is from this cause that we have suffered most within the last year. Special efforts were made last spring to win back lost trade, and while for a time it appeared that we had fully succeeded, a sudden change in the American situation upset all calculations and may, if we are not careful, throw us back again to old conditions. There is no doubt, however, that Nova Scotian coal will find a growing market in the territory lost during the war; but if the profits made are such that it will not encourage the opening up of new collieries, then the industry will not make the progress demanded of it.

Nova Scotian Coal More Expensive than American Coal

If the miners of Nova Scotia could be made to see that American coal mining conditions to a very large extent govern our Canadian industry, a long step forward in finding a remedy would be made. Until they see that American competition limits their earnings and determines their standard of living, they will not be in a position to take advantage of the place they should occupy as feeders of the eastern coal trade. With hearty co-operation, within a very short time employment all the year round might be made general in the mines of the whole province. But in order to procure this, miners should be taught to understand the coal industry of their Province as it is related to that of their competitors in the United States. Whether or not we unite in an international labor organization to advance the interests of miners, we cannot overlook the fact that certain American coal fields, because of the favourable position of their coal seams, their quality, their thickness, their depth, their dip and their level in a country with a fairly equitable climate, have advantages that cannot be set aside by any artificial regulation. Providence has so willed it, and man cannot alter the conditions.

Herbert Hoover's Diagnosis

This feature of the coal problem has been forced upon the public notice in the United States in a way that may lead to a practical solution of their, and our own mining problems. Speaking to the Salesmen's Association of the American Chemical Industry in New York, Herbert Hoover, Secretary of Commerce, declared that he did not believe that great solutions of labor difficulties are to be found in emotional denunciation, but in sober scientific examination. "When the public can be made the victim of infinite loss and suffering by such disagreements as we have witnessed, when the whole nation can, once every two or three years or less, be pushed to the edge of the precipice of want and commercial collapse, when our public utilities, hospitals, schools and kitchens are dependent upon short rations of non-union coal, when the federal government is forced to interfere with business and transportation to secure even this movement to essential points; when hundreds of thousands of workers not only in the industry but outside of it are thrown into skimping and starving when the nation is made to suffer the shame of Herrin and rampart crime that has followed a train of strikes then some examination of our industrial sanity is called for." The speaker pointed out that there were two distinctive problems for which constructive solutions were needed employer-employee relationship and economic reorganization of the industry. "Labor" he said "is struggling to set up remuneration based on such day's pay and such piece work rates as give 60 per cent. of the

employed. Labor is thus honey-combed with the worst of stimulants to unrest—insecurity of employment. At the same time men who have the opportunity to work full time in regularly operating mines earn returns far above the average income of our most prosperous farmers and other workers. There can be no solution either to the operators or to the workers so long as this condition continues."

Canada, which imports more coal from the United States than is produced at her collieries, is largely dependent upon the conditions here described. With the exception of the coal mines of Western British Columbia, which, because of an agreement based on a sliding scale, continued to work throughout the strike period, all Canadian collieries were for some time shut down. There are no non-union mines in Canada as in the United States and no source of coal supply in case of a strike. If the National Coal Commission of the United States succeeds in finding a solution of the problem in hand, Canada stands to benefit as well.

Other countries, such as Australia, have been working on the lines suggested by Mr. Hoover, and to some extent have been able to regulate their industries by moderating the fierce conflict of competition. To do this the American Commission has a big job on hand, and the closing up of 40 per cent. of the bituminous coal mines may be beyond their power. To determine the number of miners that must be shut down in any locality and the number of miners that must seek employment outside of the coal mining industry in a country where restraint of trade is forbidden except by the labor organizations, and to make recommendations looking to the prevention of labor disputes or at least keeping them within reasonable control is, as Mr. Hoover says, the duty imposed on this Commission by a people weary of idiotic warfare and futile attempts at solution. Mr. Hoover agrees that no solution is to be found in arbitration.

Sliding Scale of Wages

The sliding scale of British Columbia is interesting as an experiment and strikes us as the better way of adjusting wages. As we understand it, wages are adjusted on the cost of living principle. This is a new departure from the sliding scale principle as first worked out in Great Britain when wages went up and down with the market price of the commodity. A basis of agreement is necessary in either case. When once this is laid down adjustments are not difficult. It does seem, however, that no permanence can be attached to any system of wage settlement that recognizes only one side of the question. During the war the cost of living was given by all labor leaders as one of reasons why wages should be increased. When the cost of living began to fall after the war, labor leaders especially those of Nova Scotia openly stated that the cost of living had nothing to do with wages. On the other hand operators claimed that wages must be based on the ability of the industry to pay wages. There is, no doubt, a certain amount of truth in the argument of each; but somewhere between the working out of these two principles should be found a basis of adjusting all labor disputes. It might be unnecessary to return to a monthly or even a three months adjustment of wages; but when market prices are fairly steady throughout the year, it might be possible to make agreements on the basis of the past year's cost of living and prices received for the commodity or articles sold. There are, we know, a large number of those whose work is that of transportation, etc. who are not producers; but having a basis of settlement for the basic industries, all others would naturally follow.

A COURSE IN INDUSTRIAL METALLOGRAPHY

Under the auspices of the department of Metallurgy at McGill University an extension course in Metallography will be given as in previous years, by Messrs. Harold. J. Roast F. C. S., F. C. I. C., and Charles F. Pascoe F. C. I. C. The student need have no previous knowledge of the subject.

The course consists of fifteen periods, held on Monday nights at the Chemistry and Mining building McGill University, commencing on Monday November the sixth at 8 P. M.

Application should be made to either of the lecturers, their address being McGill University, department of Metallurgy.

The fee for the course is $20.00 payable to the Bursar.

In as much as only twelve members can be accomodated at one time students will be enrolled in order of their applications.

In past years the class has been composed of mechanics, engineers, chemists, and those desiring a winter hobby, or whose business brings them in contact with metals and who desire to have more knowledge of their composition. NO PREVIOUS KNOWLEDGE IS ASSUMED and the course is essentially practical from first to last.

If any students from a previous year desire to continue their work provision will be made for an advanced course if sufficient members are obtained.

Ferrous and non-ferrous metals are dealt with equally, training being given in preparing them for examination under the microscope and finally photographing the various structures developed.

PROFESSIONAL ENGINEERS OF ONTARIO

The organization for Registration of Professional Engineers under the Act passed at the last session of the Legislature, has been completed, and today the Association has opened a permanent office at 96 King St. West, Toronto Brig. Gen. C. H. Mitchell is President, and Mr. Robert A. Bryce, Vice President of the Provisional Council, which comprises representatives of each of the five branches Civil, Mechanical, Electrical, Chemical and Mining. Mr. R. B. Wolsey has been appointed Registrar and Secretary Treasurer.

The reconstruction of Britannia Beach is advancing rapidly. The concrete work for the new mill is almost completed and a start has been made on the steel erection for the fireproof mill building. Considerable machinery, including cranes, hoists and concentrating and screening machinery has arrived and the rest of the plant is expected shortly. Mill construction should be completed about the end of the year. When the new mill is in full operation Britannia will be the largest producer of copper in the British Empire with an output fo abont 40,000,000 ponnds of copper per annum.

The largest cargo of steel products ever shipped to the Antipodes cleared from Sydney, Nova Scotia, on September 20 for Australia and New Zealand, with 2,200 tons of the output of the Dominion Steel plant on board.

It is reported that a 3,000,000-feet flow of gas has been struck at Barnwell, near Taber, by the Calgary Gas Company. A flow of gas was also struck during the past week at Vauxhall, on the farm of the Otis-Staples Company near Medicine Hat.

EDITORIAL

The channel chiefly used by the promoter to reach the public is the newspaper advertisement... The majority of schemes to which the public are invited, by the advertising method, to subscribe, may be regarded with suspicion. — *J. C. Gwillim* — 1907

GENUINE AND COUNTERFEIT

In mining promotions, as well as in all other varieties of promotion and in most other businesses, there are varieties that range all the way from the *bona fide* investment to the downright swindle. In the mining field, examples of the latter are constantly before our eyes, particularly in the daily press, whereas the former is still so rarely found consorting with the less reputable undertakings on those pages that an actual occurrence is well worthy of remark.

When making the original announcement of the incorporation and operations of Continental Mines some weeks ago, the *Canadian Mining Journal* intimated that those back of the undertaking would probably give an opportunity to the public to participate, to a small extent at the very least, in what is considered a very promising mining venture. This has been done.

Simultaneously in New York and Toronto there was offered to the public last week 250,000 shares of Continental stock out of a total of 700,000 shares. The company already owns twenty-seven claims at Kirkland Lake and the Colonial property at Cobalt. These were acquired privately by the New York mining men responsible for the organization of Continental Mines. The brokers to whom the public issue of stock has been entrusted state unequivocally that when this stock shall have been sold, there will be over a million dollars in the treasury, as well as 80,000 shares of stock unissued and available for the purposes of the company. The financial position of Continental Mines needs no comment. It is well in accord with the financial ability and the personal reputations of the men who grace the company's board of directors.

Alongside the dignified announcement of this issue of Continental shares, and attempting to simulate the conviction of confidence in the venture that radiates from it, are myriad advertisements of stock in gold mines in the same golden north country. We need not particularise. Suffice it to say that, so far as we have observed, not one of these advertisements offers stock on which there is more than a remote chance of drawing dividends, and a number of them approach very closely or even cross the line where the untruths they insinuate, if they do not state them, are subject to process of law. As usual, the host of parasites in human form are taking eager advantage of the "gold boom" to separate the unwary and their loose change—and the daily newspapers and the Royal Mails are the chief agents they employ for the purpose.

It is very hard, if not impossible, for the uninitiate to distinguish between the genuine and the counterfeit opportunity for investment in mines. The investing public have still a great deal to learn about the mining industry.

INSTITUTE MEMBERSHIP

At the meeting next month in Vancouver of the Canadian Institute of Mining and Metallurgy, "Institute Policy" is to be, once more, a subject of debate and, doubtless of very lively debate. The Secretary, Mr. G. C. MacKenzie, will, presumably, uphold his stand for an Institute of widely inclusive membership, representative of every phase of the mining industry and working for the advancement of the industry by every legitimate means. Mr. H. G. Nichols and Mr. T. A. Rickard, who also are to address the meeting, have shown a decided preference for an exclusively technical society, whose prime object it is to promote the interests of its members first, and by this means to forward the interests of the mining industry as a whole. Last year, the Western branch of the Institute was solidly in favour of the technical society. We hope that this year there will be sufficient difference of opinion to provide for a well rounded discussion of this most important question.

Whatever the conclusion may be as to the Institute's policy on membership, there is a related question that has been almost completely neglected by the Institute up to the present. The Institute has never adopted any policy of self regulation such as would tend to give its members a professional status in the public eye. Now that the mining engineers of Ontario have, at their own request, been excluded from the provisions of the Professional Engineers Act of Ontario, and since in the other provinces a large, if not the larger, part of the mining engineers are opposed to this form of regulation, it is incumbent upon them all to provide some other form of regulation that will attain the end desired by all without including what some may regard as unnecessary and impossible structure.

If the mining engineers of this Dominion are to be a coherent body, influential and respected as is their due

they must make it plain, to themselves and to all the world, that they are subject to the self-regulation and discipline which alone can promote unity of purpose and of action. If those involved in such an attempt at co-operation are a heterogeneous lot, the effort is foredoomed to failure; they must be men whose object in life is, in the main, the same. Hence we can assume safely that it will never be possible for the whole Institute as at present composed, and much less with the addition of the larger numbers it is proposed to enrol as members, to undertake and fulfil the regulation of professional mining engineering practice that now is so urgently required in Canada. Only a carefully selected body of mining engineers can fulfil that purpose.

How can this object be accomplished? We are convinced that the object of the founders of our Institute, as recorded both in the words of the constitution they framed and in their subsequent actions, intended that it should represent the mining industry as a whole, and not merely that fraction of its personnel now known as accredited mining engineers. The fact is that when the Institute was founded there was no clearly marked class of mining engineers, as there is today. Formal education in mining engineering had barely commenced, and mining men were of necessity drawn from all walks of life. We are satisfied also that the instinct of these founders of our Institute was sound, and that today we should have an Institute including all those whose professional activities, and even hobbies, give them an interest in the products of mine and quarry. A membership thus extensive is bound to include many who are not interested in, and indeed actively opposed to, the imposing of regulations, with which the professional engineer alone is primarily concerned.

There is a means at hand, conveniently and immediately, whereby professional regulation of mining engineers throughout Canada can be effected, without recourse to restrictive legislation and without altering the character of our Institute in such a way as would destroy, in large measure, its present usefulness. For some time past our Secretary and Council have been enrolling Professional Members of the Institute. The credentials of applicants are scrutinized very carefully, and where necessary private and pains-taking inquiry is made as to the professional status and the character of the applicant. Here there is, already enrolled and with fees already paid (we hope!), the very Society that numbers of our Institute members desire. It remains but to get together, as the Professional Mining Engineers of Canada, and to "get busy." So far as we can see, there is nothing in the constitution of the Institute to prevent a section within it working for a specific object that is supplementary to, though distinct from, the object of the Institute as a whole. How such a sectionalizing of the Institute would effect its activities, it is difficult to predict; but it is certain that a society of professional mining engineers outside the Institute would be much less likely to co-operate fully with the remaining units of the industry than would such a society inside the Institute.

It seems fairly certain, from present indications, that the Institute as a whole wishes to retain its present, and original, inclusive membership. We suggest the above means of effecting the end desired by those that would have exclusive membership.

SPECIALISTS IN HIGH-GRADE STEEL

As has been pointed out more than once in these columns, if Canada is to have an indigenous iron and steel industry, it must rest principally upon some natural resource in which she excels. Only thus can international competition, which is more and more a factor in the operation of national industries, be met successfully. Hence to gauge shrewdly the chances of the success and growth of any branch of the Canadian industry, one must examine the basis of natural resources upon which it rests, as well as the resources of human energy and initiative that will put to use what nature has provided.

At present Canada has no production of iron ore and so it goes without saying that, from the national point of view, our basic production of iron and steel is not only on an insecure foundation, but is such, in central Canada at least, that it cannot hope to compete on equal terms with our neighbours who supply us with the raw materials. It may be that the present case will be improved as time goes on by means of progress in ore-dressing and ferrous metallurgy that will make our ores of iron commercially available. We are confident this will be the outcome of progress now foreshadowed.

In the meantime, there are certain undoubted advantages possessed by our country that can be, and are being, used by some of our iron and steel men. Principal among these is cheap electric power, of growing importance with the increasing demand for high-grade and alloy steels. We are well off for some of the alloying metals, such as nickel and cobalt, though we still import others. Chief among our advantages, though, is the native ability and energy of Canada's sons, without which the best of natural advantages is of little avail.

Elsewhere in this issue we print a short description of the works and products of the Hull Iron and Steel Foundries. A growing proportion of the products of this foundry is composed of the high-grade, specialized materials mentioned above, all of them made in the electric furnace and many of them subjected to special after-treatment. Not only has the best of standard practice been adopted in order to ensure superior quality, but Mr. Coplan has done a considerable amount of original research to good effect. Given correct technique, good workmanship and sound business management, progress depends upon original research and the commercial application of results thus obtained. On this basis we would judge that the Hull Iron and Steel Foundries is in a fair way to expanding, with our growing metal industry, to

proportions more nearly commensurate with Canada's vast territorial extent and her promise of industrial development.

WHO IS RESPONSIBLE?

The disaster by fire in Temiskaming district has shocked us all into the consciousness that there is something radically wrong with conditions that will allow a widespread fire to originate in a settled, or half settled, community. By the irony of fate, this holocaust was timed in the midst of Fire Prevention Week. The suffering throughout the fire swept district has been alleviated so far as is possible. How can a recurrence of this frightful destruction be prevented? Such preventive measures as are possible are a matter of grave concern to the northern mining communities, always subject to the threat of the fire fiend.

There is a series of well conceived regulations for the prevention of forest fires. Were these regulations observed, there would be few fires, if any. Forest fires originate from the non observance of the regulations. Fire rangers are employed at public expense to see that the regulations are observed, and the work of these guardians of the law, ineffective as it may have been in many cases, has in the aggregate prevented a deal of useless and senseless destruction.

On the assumption that the season for fires had passed, the fire rangers were withdrawn, by order of the Department in Toronto, on October 1st. That this assumption is false is shown not only by the present case, but by the periodically recurring instances of an October so dry that it invites conflagration. If the Department of Lands and Forests has allowed economy to interfere with safety, it is culpable. There has been circulated in the daily press the flimsy excuse that the settlers had asked for the withdrawal of the fire rangers on October 1st. Of course they would do this—they want to get along with clearing their land as soon as the crops are off; but such a request is no more reasonable than it would be from a fishing party in midsummer, if the danger of fire remains after October 1st.

We respectfully suggest that the responsibility for the withdrawal of the fire rangers before the danger of fire was past be fully investigated, and that the departmental regulations that authorise such an ill timed move be scrutinised and, if necessary, amended with a view to preventing in the future the recurrence of such a mistake.

EDITORIAL NOTES

We are pleased to note that the voters of The Pas electoral district have come so near to unanimity in the choice of Premier Bracken as their representative in the Manitoba legislature. We might have wished for a miner to represent what is essentially a mining community; but Premier Bracken's record shows him as a man of such wide interests and of such sterling character that we are confident that he will upset all precedent, and will fulfil his pre-election promise to guard and guide the interests of his miner constituents in Manitoba's north-land.

Lightning River is being "boomed" in some quarters in a way that augurs ill for its progress as a genuine centre of mining activity. But the report of Mr. C. W. Knight, which we publish today, provides geological evidence of the district's possibilities as a producer of gold that the boomsters have missed. Mr. Knight's conclusions can be put to the test only by the painstaking and expensive surface exploration and diamond drilling necessary in a region where rock exposures are few and far between and the intervening drift is deep. We hope that his favourable report will stimulate the genuine work of exploration without affording to the unscrupulous an additional means of parting fools and their money — but that is an idle hope!

The Canadian National Railways traverse the larger part of Canada's mineral lands, productive and potentially productive. To such an extent is this the case that it can be only by means of mineral production that the Canadian National Railways will be made to pay. We are pleased to note, as evidence of an active interest in this question and an appreciation of its prime importance, that a pamphlet written by Mr. Price-Green has been published, drawing attention to our mineral resources. This pamphlet is described briefly on another page.

It is certainly more obvious to the mining man than to the layman, however clearly the case may be presented, to what a large extent a modern railway depends upon mineral products for its profitable operation. There is no doubt that Sir Henry Thornton, the newly appointed head of the Canadian National Railways, is conversant, as is the thoughtful miner, with this fact. It will be interesting to note by what means Sir Henry will proceed to put this idea into concrete being.

DAWN THE METAMORPHOSIS

From out warm blankets, in the heartless dawn,
Without the vaguest chance to stretch or yawn,
Wet socks and boots, and fingers numb with frost,
Your feelings raw, your temper nearly lost
Lo! at his fire the heaven sent cook performs;
And in a trice a dish of coffee warms
Your gelid vitals—Lord, but that was good!
Your grouch evaporated while you stood
With outstretched hand, and eagerly did wait
The heaped up riches of your breakfast plate
Breakfast absorbed, (your slightly loosened belt
Proved it had tasted well as it had smelt)
You saw the dawn, no longer chill and gray,
A golden promise of a glorious day.

I. C. M.

A Modern Alloy Steel Foundry

HULL IRON AND STEEL FOUNDRIES, LIMITED

The present day iron and steel metallurgy of Canada is characterized to a growing extent by commercial establishments peculiarly suited to Canadian conditions. One of our chief assets in building up an indigenous iron and steel industry in Central Canada is, and will continue to be, the availability of cheap electric energy in large quantities. Therefore an iron and steel plant whose operation is based primarily upon this natural resource is likely to endure and prosper. Such an one is the Hull Iron and Steel Foundries, Limited, at Hull, Quebec. This plant has an extensive site beside Hull West station on the Canadian Pacific Railway. It is of thoroughly modern construction and design, and may well serve as an example of the steel foundries that are bound to be built up at various strategic points throughout Canada. Indeed, this movement is already well under way, and will keep on so long as the higher grade of product furnished by a steel foundry, and particularly by an alloy steel foundry, continues to be in growing demand.

Products of the Foundry

The products of the Hull Iron and Steel Foundries are principally plain steel and alloy steel castings for railway and mining use. There are made complete locomotive sets, including frames up to 36 feet in length; car castings and general railway castings; manganese steel guard rails; machine moulded steel gears, up 15 feet in diameter; manganese steel liners and forged balls for ball mills; gyratory crusher heads and liners and crusher jaws of manganese steel; and alloy steel stamp shoes and dies. Besides these there is a rapidly increasing production of a special steel grate bar, which will be described in detail below.

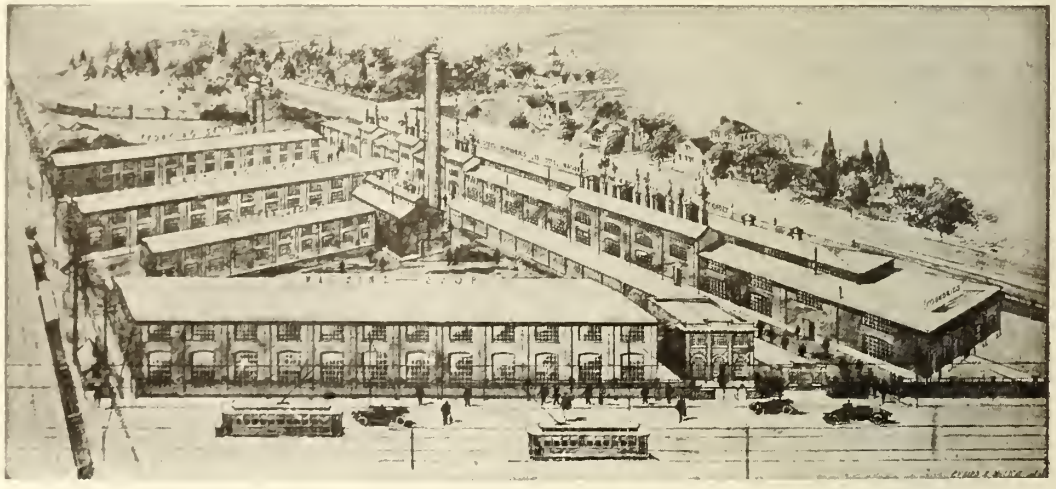
Most of the output of castings consists of plain carbon steel, as is required by the trade. But a growing proportion is of the more durable, though more expensive, alloy steels. Chief among these latter is manganese steel, which has become invaluable for use in crushing machinery and in certain parts of railway equipment since its historic discovery by Sir Robert Hadfield. Chrome-nickel, chrome-vanadium and any other alloy steels are produced as required, but their use is very limited at present. Most of the alloy steel products are subjected to heat treatment to derive the full benefit of their content of the rarer metals.

Heat-Resisting Grate Bars

Mr. Coplan, president and general manager of the Hull Iron and Steel Foundries, has a full measure of that inquiring disposition that leads to research and experiment and thereby to progress and prosperity. After two years of experimental work, he produced a grate bar of heat-resisting alloy steel especially suited to withstand the exacting conditions of the locomotive fire-box. The sample sets of bars originally installed have now been continously in use for 2½ years, are still as good as new and will apparently last indefinitely.

The chemical composition of this useful alloy has been patented in the United States and Canada. The grate bars have been adopted under the regulations of the United States Railways, and an export trade has already been commenced. The steel grate bars are 25 to 40 per cent. lighter than cast-iron bars, and consequently their first cost is only slightly higher. They are, of course, useful in stationary boilers, especially where standard shapes and sizes are required; but where only a small number of a special design are required, the cost of the requisite patterns is a serious consideration.

The present capacity of the plant is 600 tons of castings a month. This is to be increased shortly to 1,000 tons a month.



General View of Plant —Hull Iron and Steel Foundries.

Main Foundry Building

The main building, containing all the principal facilities of the foundry, is 680 feet long and 100 feet wide, of three-bay design. The central part, 50 feet wide, is used for moulding and casting. Across one end are the facilities for making cores. Ranged along the two side bays, each 25 feet wide, are the various other items of foundry equipment, so arranged that material moves always in one direction down the long building.

The core-making department is served by six small jib cranes of four tons capacity. The main bay has two 50-ton and one 10-ton electric travelling cranes, running its whole length. A railway siding enters the delivery end of the building, and another siding, outside, brings raw materials along the side on which the melting and refining furnaces are placed. The side bay next this siding can fairly be called the melting and forging bay, and that on the other side, the finishing bay, the central bay being used principally for casting.

Melting and Forging Bay

Along this bay there are ranged in succession core ovens and drying ovens for moulds; a small cupola and two Tropenas converters; a Héroult electric furnace; an annealing oven for castings; a reheating oven; two small forges; and welding apparatus. A number of these items of equipment deserve more detailed description.

The cupola and Tropenas converters are not at present in use having given place to the adjoining electric furnace. Their capacity is 1½ tons per heat, and each can handle 10 heats in 24 hours.

The annealing oven is oil fired, and will take a casting up to 30 feet in length. As locomotive frames up to 36 feet in length have been made in the foundry, this capacity is required. The reheating oven, next the forges, is 4 feet by 12 feet, and is also oil fired.

The Héroult electric furnace is of the standard three-phase type, with a capacity of 25 tons in 24 hours. It produces 6 to 7 tons per heat. It is basic lined, is fitted with 6-inch graphite electrodes, and uses a maximum current of 1850 horse power at 110 volts. The raw material used is principally a good grade of heavy melting scrap. The basic hearth allows of a very complete removal of phosphorus from the charge under an oxidising slag, which is removed. A new reducing or "carbide" slag is then built up, which removes sulphur and oxides from the bath of steel, as well as providing a cover under which the ferro-alloys required can be added with great precision. It is the use of this reducing slag for finishing the steel that makes the basic electric furnace so eminently useful in producing the highest grade of steel products. In skilful hands, it will give steel equal to the best made by the crucible process, at a fraction of the cost. Due to its strong refining action first under oxidising and then under reducing conditions, all the impurities that commonly bother the steel maker can be effectively removed, even when the melting stock is far from pure.

The additional Heroult electric furnace it is intended to install shortly will be smaller, of three tons capacity.

The forges are used principally to make the well-known Hisco balls for ball mills. They are of 900-pound and 1500-pound size, respectively. The steel billets for the balls, as cast, are lozenge shaped. In the forges they are hammered into spheres, thereby acquiring the toughness characteristic of forged products.

For welding, both oxy-acetylene and electric apparatus are available as required. It is not generally realized that no single welding equipment is suitable for all and sundry purposes; hence the necessity for having available more than one means for both fabricating and reclaiming materials by welding.

Finishing Bay

In the finishing bay there are an enclosed sand-blast with respirator for workmen, an assortment of swinging and stationary grinders, and a heat treatment furnace for manganese steel. This bay provides also ample storage for moulds.

The furnace for heat treatment is oil fired, 6 feet by 8 feet inside dimensions. It is equipped with a pyrometer for precise heat control, this same pyrometer having a thermo-couple in the annealing oven as well to which it can be switched. The wonderful qualities of the Hadfield manganese steel are brought out simply by quenching from a prescribed temperature, which appears as a bright red heat. The high content of manganese imparts to the alloy its characteristic toughness only after this quenching, which is effected in a tank of running water directly in front of the furnace, into which the red-hot castings are dropped from the furnace door.

Accessory Equipment

The foundry is well served with the accessories required by modern practice. There is a well-equipped machine shop including a 15-foot boring mill (used for finishing large gears), a large radial arm drill, and the ordinary machine shop tools. Apart from the large boring mill, the shop is used exclusively for the internal repair work and construction of the foundry.

The adjoining compressor room contains a vertical, high-speed, direct connected air compressor to provide air for rammers, oil-fired furnaces, etc. There are three small belt-driven compressors used as auxiliaries and spares. In the same building is a motor-generator set to provide direct current for welding.

The electric current used in such large quantity in the plant is brought from the Chaudière Falls generating plant, close by, at 11,000 volts, and is stepped down in a sub-station at the plant to 220 and 110 volts.

There is a separate commodious building for pattern storage, well separated from the rest of the plant on account of the risk of fire. Another building provides ample storage room for stock of the various sorts required.

A Corner of the Chemical Laboratory

All loading and unloading of scrap and of finished products (except the non-magnetic manganese steel castings) is done by means of an electro-magnet operated by a locomotive crane. This has proved a most economical and effective means of handling the foundry's raw material and products. The electro-magnet is used also for reclaiming scrap from the sand of the foundry, having displaced a special machine formerly used for this purpose.

Offices and Laboratory

A notable feature of the foundry is the attention paid to its administrative equipment. The office building is commodious and well-equipped, and its appearance is outstanding in both Hull and the adjoining Capital City. Well-planned garages are available for those who use cars.

The top storey of the office building contains the laboratory, which is fitted out to fill the needs of the foundry. Every heat of steel is analysed. A competent analyst is employed and every advantage is taken of the art of the modern metallurgical chemist — an art that, though so highly essential to the success of a modern foundry, is occult to and shunned by so many foundry managers even in these enlightened days.

Though every facility is provided for the control and direction of the operation of the foundry by means of the chemist's art, its products are sold on a basis of practical

performance. Of course castings and forgings are made to standard analysis, or to special analysis if required. This is in complete accord with modern practice. As yet we know too little of the constitution of metals, and more particularly of alloy steels, to allow us to predict physical performance on the basis of even the most accurate and detailed chemical analysis. The analyst is an essential factor in a well ordered foundry; but the quality of the product is still dependent mainly upon the foundryman's practical skill.

First Aid Building

A striking example of the care and thoroughness with which this foundry has been planned and is operated is its first aid building. This is a separate structure, close to the entrance to the works and next the time-keeper's office. It is fully and expensively equipped with all the necessary appliances and supplies, and is served by an attendant trained by the St. John's Ambulance Corps.

Mr. A. H. Coplan is president and general manager of the Hull Iron and Steel Foundries. Mr. F. H. Cross is assistant manager. Mr. Coplan is to be congratulated heartily for his success in building up a unit in our indigenous iron and steel industry that is a credit to Canada and points the way to further development.

RED LAKE DISTRICT

by E. L. Bruce

The following brief report by Dr. E. L. Bruce to the Department of Mines, Toronto, was made on his return from the field recently and has been made available for immediate publication through the kindness of Mr. Thos. W. Gibson, Deputy Minister of Mines.—Ed.

The rocks in the vicinity of the recently reported silver fields along the shores of East Bay, are lava flows largely altered to greenstones or to chlorite schists. Interlayered with the lavas are light colored quartz porphyries that are also probably volcanic rocks. Along the east shore of the bay the rocks are purple and green schists of somewhat doubtful origin with many rusty zones in which there is considerable carbonate. Calcite also occurs as blebs in the greenstones and as small stringers. These rocks are intruded southeast of Red Lake by granite. Several miles west of East Bay similar volcanic rocks are associated with slate, iron formation and some bands of conglomerate. All the rocks are much disturbed.

The original discovery, which was the only one made at the time of examination, is a vein four to six inches in width, with some parallel stringers, consisting of about equal quantities of quartz and galena. The galena is said to carry high values in silver. No native silver was seen by the writer. It is possible that silver sulphide or other silver minerals may be found on further examination but they were not recognized in the field examination of the specimens. The original vein had been traced only a short distance. The heavy forest cover and high water level of the lake combined to make prospecting rather difficult.

It is possible that important developments may follow this find. The original discovery vein is small even though it should prove to be high grade, but further prospecting may uncover larger deposits. It should be clearly understood, however, that both the mineral association in the vein and the rocks in which the veins occur are quite different from the native silver occurrences of Cobalt and Gowganda. It will require a considerable amount of thorough prospecting and development before the value of the new discovery can be properly determined, and reports of the size of the new field and the values found in the veins should be accepted with much reserve.

MINERALS AND MINING INDUSTRIES on the CANADIAN NATIONAL RAILWAYS

There has just been issued by the Industrial and Resources Department of the Canadian National Railways a pamphlet of 64 pages written by Mr. C. Price-Green, Commissioner of that department. This little volume describes concisely, yet comprehensively, the mineral deposits, developed and undeveloped, that have been found along the Canadian National lines, from Atlantic to Pacific, and from the international boundary to Fort MacMurray.

An introductory section of six pages summarizes the principal geological features of Canada and delineates the mineral-bearing areas. Stress is laid upon the extreme importance to any railway, and particularly to the Canadian National Railways, of mineral development. Only by means of the volume of freight traffic incidental to wide-spread mining operations can the National lines be made to pay or even be self-supporting.

The economic minerals are dealt with in alphabetical order, their number (forty-one) indicating the wide variety available. The chief deposits are described briefly, and others of prospective value alluded to. References are given to more voluminous sources of information. Many practical suggestions are included with a view to stimulating the use of these minerals.

Throughout the pamphlet, Mr. Price-Green maintains the forward outlook. He mentions opportunities and practical possibilities on every page. Progress in the past he interprets in the light of greater progress for the future.

The pamphlet can be obtained by those interested from the Industrial and Resources Department, Canadian National Railways, Toronto, Ont.

SOUTH CAROLINA WHITE CLAYS

The methods of mining and preparing white clays for market in the vicinity of Langley, South Carolina, are described in Serial 2382, by W. M. Weigel, mineral technologist, just issued by the United States Bureau of Mines. Langley is about nine miles north of Augusta, Georgia. The clays mined in this district are sedimentary kaolins with few impurities. The prevailing color is white; at times the color is smoky grey or pink, and occasionally strong pink to lavender. The lighter colors usually become white on exposure to the air and on drying. The lower parts of the beds are usually the whitest. These kaolins are fine grained in texture, and have good plasticity; their tensile strength is from 8 to 36 pounds. They generally slake readily. Their specific gravity is from 2.50 to 2.25. The clays in the district are well adapted for use in paper stock, for which they are mainly used, and in pottery and china ware, without washing. In the district as a whole, considerable reserves of clay are yet untouched, hence the industry can be considered fairly stable. Serial 2382 may be obtained from the Bureau of Mines, Washington, D.C.

New Plant of Northern Ontario Gold Mine Possesses Unique Features

by F. A. McLEAN

A new mining plant possessing a number of unusual features was recently installed by one of the Northern Ontario Gold Mines.

The entire equipment was furnished by the Ingersoll-Rand Co., Ltd., and consists essentially of a Four Drill Class "EL-1" Air Compressor with unloader and receiver, belt-driven from a 2 cylinder, 2 stroke cycle, "Fairbanks Morse" Oil Engine. The engine is equipped with friction clutch pulley and small auxiliary starting engine and compressor.

Other equipment includes a 6x8" Class "SSR" "CIRCO" Double Cylinder, Single Drum, Reversing Air Hoist with a capacity of 4,000 lbs., 500 ft of plow steel cable, 4ft. sheave wheel, ore buckets, ore cars, pump, water tank for drills, compressor and engine; piping, hose steels, blacksmith tools, 2 "DDR 13" "Jackhammers" a New Jersey Forge Blower and a complete set of tools and spares for making minor repairs to the important parts of the outfit.

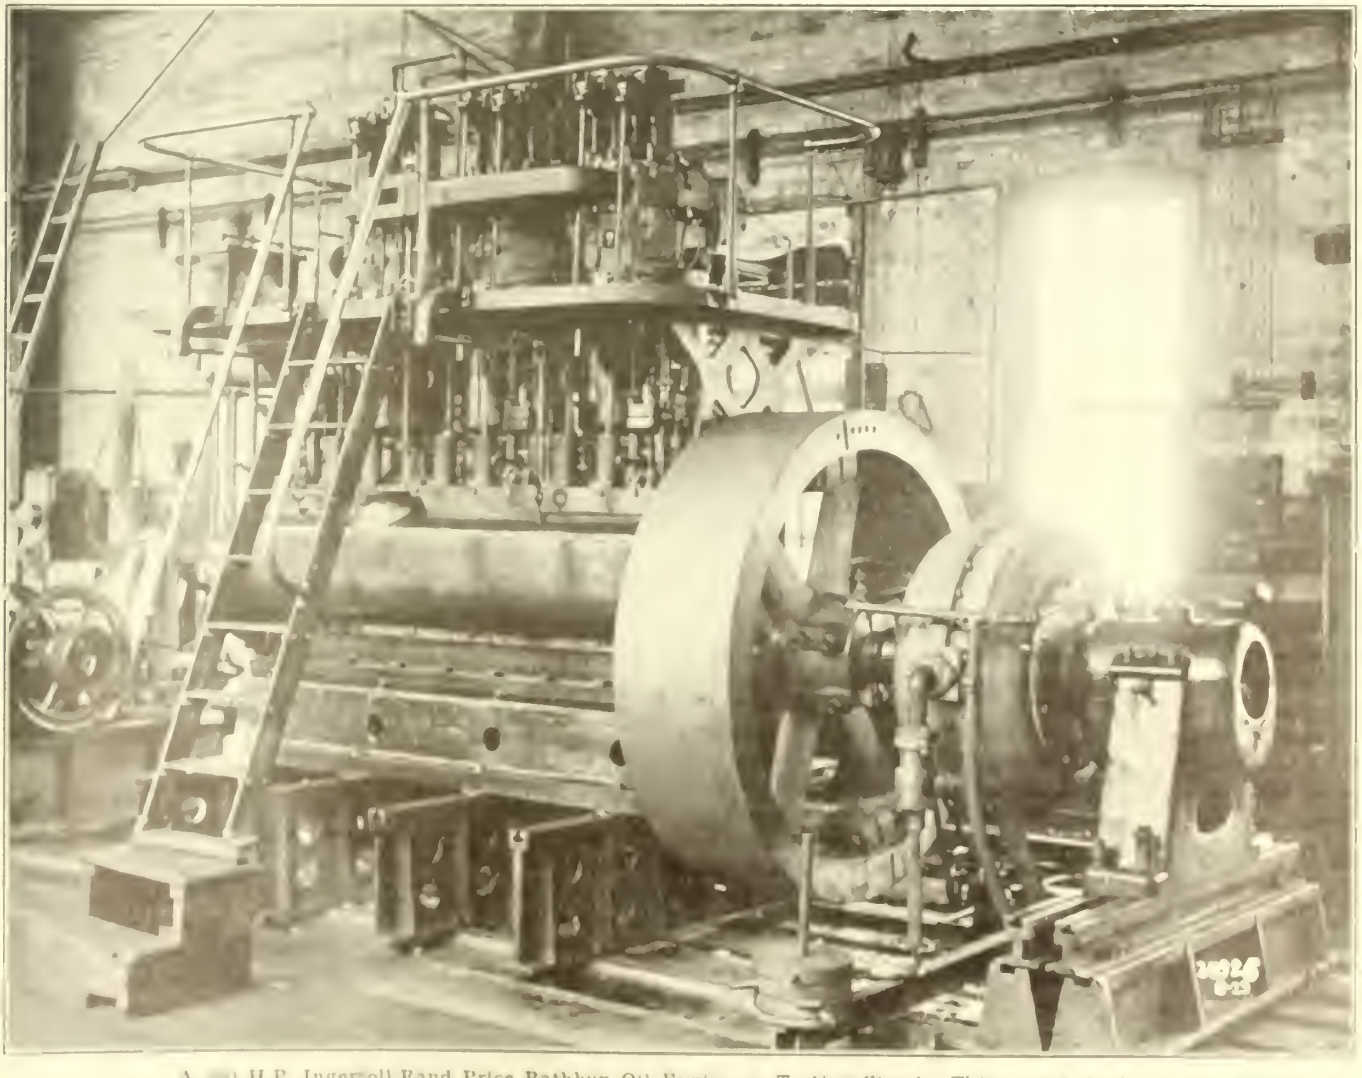
In such respects as completeness of the equipment furnished and the urgency of the delivery—four weeks—this installation resembles the outfits shipped into the Rossland camps twenty-five years ago. A favourite plant at that time was a "Rand" class "C" Compressor with Receiver, 60 H.P. boiler, hoists, drills, skips, buckets and all piping cut to length ready to set up.

The compressor chosen for the plant under discussion is of the single stage, centre crank, enclosed frame, straight line type with 12 x 12" air cylinder and a piston displacement of 340 cu. ft. per minute at 220 r.p.m., the approximate shipping weight of which is 5,200 lbs.

This type of compressor is particularly well adapted for this class of service owing to its simplicity, dirt proof construction and automatic lubrication and regulation at all speeds.

The Oil Engine is of 12" bore by 15" stroke developing 75 H. P. at a speed of 320r.p.m. and weighs about 18,000 lbs. It is fired by the heat of compression and is provided with a hot tube to permit quick starting.

The selection of fuel is a primary consideration in any industrial or mining project and one upon which the ultimate success or failure of the venture often rests. The mine mentioned above is located twelve miles from the nearest railroad so that the use of coal was out of the question, owing to the difficulty and cost of transporting and storing a sufficient quantity to permit continuous operation. There is an abundant supply of wood near the property, but the operators realized, that if this was used, the more they cut, the

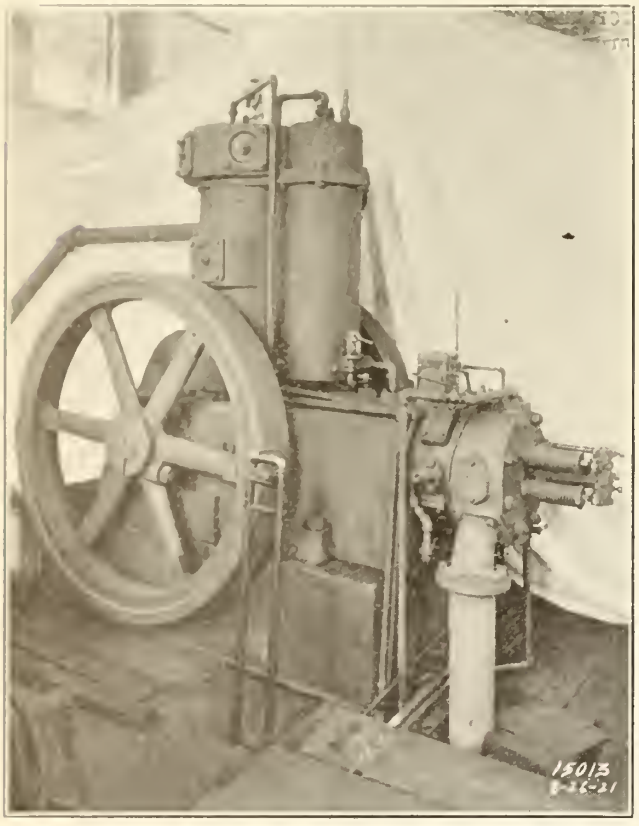


A 60 H.P. Ingersoll Rand Price Rathbun Oil Engine on Testing Stand. This type is built in sizes of 105 to 1000 B.H.P. Similar units are also furnished for Marine service.

farther they would have to transport each succeeding month's supply. This, of course, meant a constantly rising fuel cost.

After careful investigation it was found that an oil engine, of the direct fuel injection type, would give a power cost considerably lower than that obtainable with either coal or wood and furthermore, the oil could be easily obtained and readily transported.

Additional advantages in favor of the oil engine drive were simplification of equipment, reduction in labor charges, the elimination of stand-by losses and a saving in space due to the absence of boilers and accessory equipment.



"I-R", Type "POV-2", Direct-Connected Oil-Engine, Two-Stage Compressor. Similar Units are Available also for Single Stage Compression.

Modern oil engines will operate efficiently on low grades of oil, and fuels of this class are so readily obtainable and transported, that this form of prime mover, in connection with a compressor of the practically automatic, enclosed type, would seem to offer a simple, cheap and reliable source of power for the operation of hoists, drills, pumps and other equipment required in the development or operation of isolated mining properties.

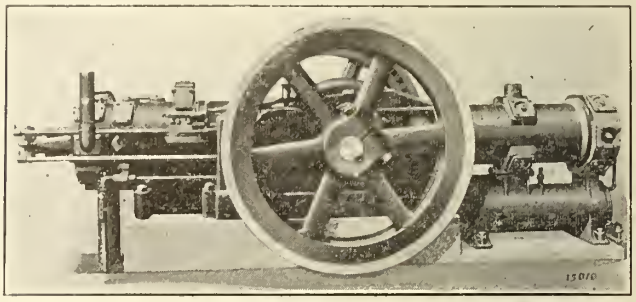
The best equipment of this class is now obtainable in a large range of sizes, can usually be dismantled into sections small enough to permit transportation over rough country, and on arrival is easily erected and operated by men of ordinary intelligence.

Due also to the rugged construction, the self-contained features and the few accessories required by a plant of this type the problem of suitable foundations and suitable protection from the elements is easily solved.

Taking these facts into consideration it seems quite reasonable to suppose that plants of this character will not only permit the developing of many promising properties that would otherwise be forced to await the construction of railroads, but in some instances may lead to a reduction in the operating costs of existing mines.

A new "Ingersoll-Rand" Direct Connected Oil Engine Driven Two Stage Compressor particularly adapted for mine service is shown in the illustration herewith.

This unit known as a "POC-2" consists of a 100 lbs. 497 cu. ft. Two Stage Air End equipped with "Ingersoll-Rand" Plate Valves directly connected to a 90 H. P. Horizontal Single Cylinder Four Cycle Single Acting Direct Injection Type "I-R" "Price" Oil Engine.



This Type Available also for Single-Stage
A 497 cu. ft. "I-R", Type "POC-2", Direct-Connected Oil-Engine Compressor, with Two-Stage Air Cylinders. Compression.

Both the engine and compressor are of the enclosed type and the former develops 17 to 18 H. P. per gallon of fuel oil having a heating value of 18,500 B. T. U. per pound.

A smaller compressor with vertical air cylinder known as the "POV-2" with a piston displacement of 271 cu. ft. of free air per minute is also furnished. Both units are also built for single stage compression.

For larger air plants or where oil driven prime movers for driving generators, pumps, or line shafts are required a vertical multi-cylinder four stroke cycle Ingersoll-Rand Price-Rathburn type engine is used. This type is made in sizes of from 105 to 1,000 B. H. P. for stationary use and in sizes of 220 to 750 B. H. P. for marine use.

DETERIORATION OF STORED CEMENT

Deterioration of cement stored in bulk is less than in bags, owing to the smaller area exposed, states the United States Bureau of Mines, as the result of an investigation to determine the cause of deterioration of Portland cement during storage and transportation. Hydration takes place only at the exposed surface, and the bulk of the cement is unaffected. Cement transported in bulk must be shipped in a tight, closed car, and must be protected from moisture during loading, shipping, and unloading. Preferably it should be used immediately after unloading at the point of destination. This practice is now followed by several manufacturers and where conditions are suitable it is becoming more common as its advantages are seen. Shipping in bulk effects a saving by eliminating the use of bags—which is an important item in the cost of cement—and it should also permit a saving in freight rates. Details of a study of the storage and transportation of Portland cement, with a bibliography on the subject, are given in Serial 2377, obtainable from the Bureau of Mines, Washington, D. C.

Lightning River Gold Area*

BY CYRIL W. KNIGHT

A discovery of native gold in quartz having been reported in the Lightning River area, on what is known as the Seagers claim, at the northwest corner of Holloway township, the writer was instructed by Mr. Thos. W. Gibson, Deputy Minister of Mines of Ontario, to visit and examine the new occurrence. An examination was consequently carried out during the latter part of August and early in September, 1922, at which time about sixty men were in the area.

The Seagers claim, No. 10,080, is about four miles north of the Cochenour claim, No. 7135, on which gold was discovered by Messrs. Howey, Cochenour and Williams in August, 1917.

The Lightning River gold area is in the district of Timiskaming, south of Upper Lake Abitibi, and includes the township of Holloway and Harker, six miles south of the lake. The area is now easy of access. Most prospectors enter it by way of the village of La Reine, in the province of Quebec, on the Canadian National railway, 72 miles by rail east of Cochrane, Ontario. There is hotel accommodation at La Reine. At the time of our visit, the Canadian Mining Syndicate, now the Abitibi Mines, was running, four or five times a week, a 35-foot gasoline boat, covered, from La Reine down the Okikodesik river, across Upper Lake Abitibi, and thence about six miles up the Lightning river to a dock. From this dock a rough "jumper" road, about two and a half miles long, has been constructed to the Seagers claim. Numerous trails have been cut recently by prospectors in the northwest part of Holloway, and the northeast part of Harker township.

In the winter season the quickest way to enter the area is by a winter road from Ramore, a station on the Temiskaming and Northern Ontario railway, 92 miles north of Cobalt. The Ramore road only goes as far as the southwest corner of Holloway township, to the Cochenour claim, No. 7135, of the Lightning River Gold Mines, Limited. A trail, however, connects the Cochenour claim with the Seagers claim at the northwest part of Holloway township.

During the past year there has been considerable activity in the Lightning River gold area, and many claims have been staked. The blue prints, for instance, issued by the Ontario Department of Mines, from the North Bay office on September the eleventh, 1922, show that much of the east half of Harker and the west half of Holloway townships have been staked and recorded. To be exact, there were staked and recorded on September the eleventh, according to the blue prints referred to above, 168 claims on the township of Holloway, 15 of which had been surveyed by an Ontario land surveyor. In the township of Harker, 155 claims had been staked and recorded, of which 7 had been surveyed by an Ontario land surveyor. In Fraserdale township, north of Holloway, four claims have been staked and recorded, while in Guibord township, west of Harker, four claims have been staked and recorded.

In a hurriedly written preliminary report of this nature, time does not permit the publication of a new geological map of the area. It is therefore, advisable, if the report is to be read intelligently, to have the most recent blue prints of Holloway and Harker township;

* This report has been issued in pamphlet form by the Department of Mines, Toronto.

these may be obtained from the office of the Mining Recorder, Swastika, Ontario. The coloured geological map of the Abitibi Night Hawk Gold Area, issued in 1919, should also be obtained from the Ontario Department of Mines, Toronto, Ontario.

Acknowledgments

During the examination, the writer was accompanied by Mr. D. G. H. Wright to whom he is greatly indebted for many suggestions and helpful discussions in connection with this brief report. To Mr. Russell Cryderman, also, the writer wishes to express his thanks for cheerfully guiding him to many claims on which work was done. It may be added that Mr. Cryderman prospected in this area in 1908 and staked some ground near what is now know as the Seagers claim.

The writer wishes to express his thanks to the Canadian Mining Syndicate, now the Abitibi Mines, for many courtesies shown, and particularly to Mr. I. W. C. Solloway who has been associated with this syndicate. Thanks are also due to the Lightning River Gold Mines, Limited, with which company are associated Messrs. Howey Cochenour and Willans.

The assays and chemical determinations were made in the Ontario Provincial Assay Office, by W. K. McNeil, Provincial Assayer, and T. E. Rothwell.

History of the Area

Prospectors are said to have explored in the Lightning River area in the years 1907 and 1908, at which time some ground near the Seagers claim was staked. Included among the pioneers were Russell Cryderman, Wm. Copper and Wm. Woodney. In those days, however, it was difficult to get capital interested in that part of the country, remote and somewhat inaccessible as it was. Moreover, prospecting for silver was more fashionable then than it is now.

In the year 1917, Messrs. Howey, Cochenour and Willans, working northeastward from Kirkland lake, discovered in August of that year, a vein of gold-bearing quartz at the southwest corner of Holloway township on what subsequently became known as the Cochenour claim, No. 7135, of the Lightning River Gold Mines, Limited. As a result of that discovery, the Ontario Bureau of Mines the following year decided to make an examination of the area, and Mr. A. G. Burrows and the writer were instructed to report on and geologically map in a general way, the Lightning River area, particularly that in the vicinity of the Cochenour claim.*

An inclined shaft dipping at an angle of 23 degrees was sunk on the Cochenour vein to a depth of 70 feet, at a depth of 50 feet, the vein is reported to have passed from a basalt lava flow into a rhyolite flow. The quantity of gold in the vein is said to have decreased when the vein entered the rhyolite. This constitutes the main work which has been done on the Cochenour.

Recently a claim known as the Meridian claim, No. 7247, in Harker township, about a mile and a half west of the Cochenour, has been attracting attention, and a shaft has been sunk to a depth of 18 feet. The deposit on this claim is described elsewhere in this report.

Finally, the discovery this year on the Seagers claim

* "Abitibi Night Hawk Gold Area," by C. W. Knight, A. G. Burrows, P. E. Hopkins, and A. L. Parsons; Ont. Dept. of Mines, Vol. 28, Part II, 1919.

of a vein of quartz containing rich gold specimens, about four miles north of the Cochenour, has aroused new interest in the area.

Rocks of the Lightning River Area

Most of the rocks of the Lightning River gold area belong to the Keewatin series, and consist of lava flows. In the south part of Holloway and Harker townships, at the properties of the Lightning River Gold Mines, Limited, the lava flows have been studied and mapped in some detail by the geologists of the Ontario Department of Mines. Fourteen flows have been recognized, having a combined thickness of 4400 feet. Most of the flows are dark green basalts or andesites, but a few are pink rhyolites. The flows have been tilted up into almost vertical positions, dipping steeply south and striking westward.

At the north end of Holloway and Harker townships, prospectors during this year have discovered half a dozen small outcrops of conglomerate, greywacké and slate. These rocks probably belong to the Timiskaming series, and are younger than the Keewatin lava flows. Owing to the heavy overburden of clay, sand and gravel, the extent of these sediments is not known. They strike westward and dip at steep angles. The conglomerate contains pebbles of feldspar-porphyry, red jasper, and chert of various colours. Some fine-grained greenstone and green schist pebbles also occur.

The great intrusion of diabase or gabbro of Ghost mountain is about five miles long and a mile wide. It is in all probability younger than the Temiskaming sediments, and Haileyburian in age.

Finally intrusion of feldspar-porphyry and quartz-porphyry cut the Keewatin and Temiskaming series and presumably the diabase or gabbro of Ghost mountain. In the Lightning River area these porphyry intrusions have not been found to be numerous, only a few small dikes having been met with. However, the drift is so widespread that it is quite possible there are large intrusions of these "gold bringers". Great masses of syenite and granite occur in Garrison and Harker townships. The geology, as briefly outlined in preceding paragraphs, may be summarized in the following table, the older rocks being shown at the bottom of the column:—

Algoman Series	Feldspar-porphyry, quartz-porphyry, syenite, granite.
Haileyburian Series ...	Diabase, gabbro and serpentine of Ghost mountain.
Temiskaming Series .	Conglomerate, greywacké, slate.
Keewatin Series . .	Basalt, andesite, dacite rhyolite.

Running in an east and west direction through the north end of Holloway and Harker townships, is a belt of schistose rocks. This belt of schist consists of Temiskaming sediments and Keewatin basalts greatly sheared. The belt extends along its strike for at least three or four miles, and disappears below the drift toward the west. It may be said to occupy, in a general way, the valley of the Teddy Bear river, most of the shearing having taken place on the north side of the valley.

While the lava flows in the south parts of Holloway and Harker townships have been tilted up into vertical positions, and therefore considerably disturbed, they are not, except in rare instances, altered to schist. Nor is the diabase and gabbro intrusion of Ghost mountain at the north end of these townships rendered schistose.

The Teddy Bear valley, bounded as it is on the north by the towering Ghost mountain and on the south by hills of little altered lava flows, forms the centre of prospecting activity at the present time.

Dome Mines Conglomerate

The discovery this year in the Lightning river area of Temiskaming sediments, consisting of conglomerate, greywacké, and slate, raises the question as to the relation of the gold deposits of north-eastern Ontario to these belts of sediments.

Beginning at the Dome mine in Porcupine, there is a belt of these sediments striking eastward for 16 miles, the last known outcrop being in German township. To the east for 27 miles the rocks are almost entirely drift covered. Then there outcrops another belt of the sediments, about nine miles long, in the Croesus gold mine area. East of the Croesus belt for a distance of 22 miles, the rocks are again almost entirely drift covered, until, in the Lightning river area, conglomerate, greywacké and slate once more make their appearance in a few places. These three occurrences of Temiskaming sediments, namely the Dome mine, the Croesus and the Lightning river, may belong to the same great east and west belt of deeply infolded sediments. In the year 1915, Mr. P. E. Hopkins suggested that the Croesus belt of sediments might be continuous with the Porcupine belt.

The Great Gold Belts in Northeastern Ontario

From 25 to 40 miles south of the great belt of sediments referred to in the preceding paragraph is another important belt of similar rocks of which the Kirkland Lake band forms the most important part. This south belt begins in Midlothian township, outcrops again in the Matachewan gold area, and is developed to the east in large volume in Kirkland lake and Larder lake. Over much of this belt gold occurs.

Thus there may be said to exist in northeastern Ontario two main gold belts which contain the most important gold mines in the Province. The belts are roughly parallel to each other and 25 to 40 miles apart. Each is in the neighborhood of 70 miles in length, and each follows a belt of Temiskaming sediments consisting of conglomerate, greywacké and slate. Occurring in, or near, the northern belt of sediments are the Dome and other mines, the nearby Hollinger mine, the Croesus and the gold prospects of the Lightning River area. The south band includes the Matachewan, Kirkland lake and Larder lake deposits.

As is well known, the beds of sediments on these two belts have been mapped almost entirely by A. G. Burrows and P. E. Hopkins.

Why Gold Follows Temiskaming Belts

Some years ago the Provincial Geologist of Ontario, Dr. Willet G. Miller, draw attention to the relation of the gold deposits of northeastern Ontario to belts of conglomerate, greywacké and slate of the Temiskaming series.

In emphasizing the broad general relationship between belts of Temiskaming sediments and gold deposits it is not meant to under-rate the immense influence which intrusions of feldspar-porphyry and quartz-porphyry have played in the formation of the gold deposits. In the prospector's mind is indelibly fixed the importance of these porphyries. "No porphyry, no gold". But the occurrence of gold in or near the two great belts of Temiskaming sediments is a matter of fact, not of theory.

Viewed from this angle, the Lightning River gold field assumes a new importance as a prospective gold area. Therefore, to the prospector we would say: *explore for feldspar-porphyry and quartz-porphyry intrusions*

in or near these great belts of sediments. Incidentally it may be mentioned that there is a band of Temiskaming sediments 25 or 30 miles north of the Lightning River area, in Steele township on the shore of Lake Abitibi, which may be worth prospecting.

The Seagers Claim

The discovery which is attracting attention at the moment is near the northwest corner of Holloway township on claim No. 10,080, about three quarters of a mile south of Ghost mountain. This claim is known as the Seagers claim. Gold was first found on it in February, 1922, by Mr. Wm. S. Seagers, who obtained the precious metal by panning. Subsequently the claim was obtained by the Canadian Mining Syndicate, now known as the Abitibi Mines, and after some stripping and blasting were done, a narrow vein of gold-bearing quartz was discovered in July. From this vein specimens of native gold have been obtained.

The discovery was made on a low, flat hill, the country rock of which is fine-grained basalt, with a light grey colour on fresh surfaces, but with a rusty brown colour on weathered surfaces. While the rock is much altered, and impregnated with rusty weathering iorn carbonate, it is not, however, schistose. The hill has been trenched and stripped to a considerable extent, and some shallow pits blasted in the rock. In these pits it may be seen that iron pyrites in small crystals impregnates the country rock but it cannot be said that the rock is heavily mineralized with pyrite. The rusty brown colour of the fresh or weathered surfaces appears to be due more to the oxidation of the iron carbonate than to the oxidation of iron pyrites.

This hill is intersected by numerous quartz veins varying in width from fractions of an inch to two or three feet. The vein from which the rich specimens of native gold have been obtained averages a few inches in width, bulging at one place to 15 or 20 inches. It is in the widest part of the vein that most of the native gold occurs. The vein strikes south about 20 to 25 degrees west, dipping, apparently, at an angle of about 15 degrees eastward. It was exposed for about 50 feet at the time of our visit, but a greater length was said to have been uncovered in a trench, which was full of water at the time of examination. The vein strikes southward into [illegible] of ground.

Iron pyrites occurs sparingly in the vein, but is more abundant in the country rock. Traversing at angles of 45 to 90 degrees across this vein are stringers of white quartz [illegible] in width from fraction of an inch to an inch or two in width.

Native gold [illegible] is also said to have been obtained from a cradle put on this hill. The pit was full of water at the time of the examination.

In various places on the hill fine gold may be obtained by panning the [illegible] mineralized material.

Some of the specimens contain feldspar and tourmaline. It appears likely that the country rock contains in places chromite, as a pale green micaceous mineral which was said to be chromite by Mr. W. K. McNeill, Provincial Assayer. Mr. McNeill found no trace of chromium, but [illegible] judging from tests which he made, that the green colour is due to ferrous iron.

An interesting feature of the Seagers occurrence is that an outcrop of conglomerate of the Temiskaming series [illegible]. Only two hundred yards away, on claim No. 10,082, about five chains south of the northwest corner post, the boundary line.

The Seagers claim is the only one in the north part of Holloway and Hawley townships on which we saw native gold. Although gold could be obtained by panning oxidized material elsewhere in this section. At the south part of these townships, however, native gold is known to occur over a wider area.

Four log cabins have been erected by the Canadian Mining Syndicate, now the Abitibi Mines.

The Meridian Claim

While the main object of our visit to the Lightning River gold area was for the purpose of examining the Seagers claim, a visit was also paid to the Meridian claim at the southwest part of the township of Holloway, about three and a half miles south of the Seagers claim. The Meridian claim, No. 7247, in Harker township, is so named because the gold deposit on it intersects the east boundary of that township; this boundary line was surveyed as a meridian line some years before Harker township was surveyed. The meridian line was subsequently used as the east boundary of the township hence the name "Meridian" claim.

The gold deposit on the Meridian claim was described by A. G. Burrows in 1918.* At that time the claim was known as the "Cochenour, in Harker township". Very little work had been done on the claim. Recently a shaft has been sunk on the ore body to a depth of 48 feet. The shaft is located about 200 feet west of the east boundary of the claim. It may be seen that the ore body dips steeply to the south, and strikes about westward.

The ore body consists of a shear zone in basalt which has been impregnated with fine-grained iron pyrites. The average width of this pyritic zone is about three or four feet; in places its width is five or six feet or more. Very little quartz is to be seen. The rock on the dump from the shaft is not schistose so it may be judged that the shearing was not intense. The rock appears to be slightly silicified, and impregnated with a little rusty weathering iron carbonate. A little finely divided native gold has been found in the pyrites zone. A grab sample of the material on the dump from the shaft was taken by the writer and assayed by T. E. Rothwell of the Ontario Provincial Assay Office, and found to contain $9.60 of gold per ton. The deposit is covered immediately to the west of the shaft by swamp and drift, said to extend some distance to the westward. This is a promising claim.

The deposit passes on the east into the Taylor Horne claim, No. 7261, in Holloway township. On this claim a quartz vein six to eight inches wide occurs in the shear zone, and some native gold has been found in the vein. Mr. A. G. Burrows has noted the presence of pyrite, copper pyrites, zincblende, and galena in the vein, and some selected material by him from the vein gave on assay $1.40 in gold.

The deposit on the Taylor Horne and Meridian claims has a length of more than three hundred and twenty five feet. As stated above it passes at the west end under swamp and drift.

In March, 1922, the Temiskaming Testing Laboratories at Cobalt made some tests on a shipment of 1820 pounds of ore from the Meridian claim. The ore was submitted by the Lightning River Gold Mines Limited. The laboratory found that the shipment contained 0.7 ounce of $14.00, in gold and 1.6 ounces of silver per ton.

After carrying out certain amalgamation and cyanidation tests on this shipment, the Temiskaming Testing Laboratory reached the following general conclusions:

1. Amalgamation will give a recovery of about 75 per cent. of the gold.

* Loc. cit.

2. Cyanidation will give a recovery of about 95 per cent. of the gold.
3. Amalgamation and cyanidation combined will give about 95 per cent. recovery of the gold.
4. Whatever method is adopted fine grinding will be necessary.

There do not appear to be any interfering elements, and even with fine grinding very little slime is formed, so that the ore is an ideal one to cyanide. Tests by water concentration on a Wilfley table indicate that the gold is probably associated with the pyrite.

Claims Near Seagers Claim

Prospectors have been attracted by a belt of schists and other less highly sheared rocks which strike westward across the north part of Holloway and Harker townships. The Seagers claim is on this belt. During our visit we examined several claims along the belt where either the rock or the ore deposits might prove of interest, and a few notes may be added regarding these claims, beginning with the most eastwardly one visited, namely, No. 11,013, in Holloway township. We are indebted to Mr. Tom O'Neill for his kindness in guiding us to this claim. At the northeast corner of the claim considerable stripping has been accomplished and some blasting has also been done. The rock here is a rusty weathering, iron carbonate schist, striking west 10 to 20 degrees south magnetic, and dipping steeply to the north. Narrow stringers of quartz and iron carbonate containing a little iron pyrites intersect the country rock. The country rock also contains a little iron pyrites. Fragmental material was noted in one place, but the rock is too much altered to determine its true character.

West of this claim about three-quarters of a mile is the "east" Remo claim, No. 8246, in Holloway township. At the northwest corner of this claim a tunnel has been driven southward into the side of a hill a distance of 35 feet. The tunnel intersects a rusty weathering brown schist impregnated with iron carbonate, striking westward and dipping 80 degrees to the south. A few stringers of quartz about an inch in diameter occur parallel to the strike and dip of the schist. A curious occurrence of dull-looking graphite is found along a few zones in the schist.

West of here about a quarter of a mile, some work has been done on "west" Remo claim, No. 8247, in Holloway township, at the north part of the claim near the trail. A vein of quartz from a few inches up to two feet in width has been found, occurring in an altered basalt impregnated with rusty weathering iron carbonate.

Two claims west of the "west" Remo, the Mining Corporation of Canada, Limited, has done some stripping in several places on claim No. 10,476, in Holloway township. On the north part of the lot a schistose pillow lava has been stripped for a length of 100 feet and a maximum width of 40 feet. The schist dips almost vertically. A few small stringers of quartz up to six inches in width occur. A minor fault follows the strike of the schist. Gold has been panned in the rusty oxidized material. On another part of the claim, where stripping has been done, the massive rock has a pale mauve colour, and is impregnated heavily with iron pyrites. At the southeast corner of the claim a trench 100 feet long and 10 feet wide has revealed finely bedded slate of the Temiskaming series, striking north 73 degrees east and dipping steeply to the north. In places these slates are highly contorted.

On the claim immediately to the north, No. 9864, in Holloway township, there is an outcrop of schistose, fragmental-looking rock ,at the southwest corner of the claim at the roadside. This claim is owned by the Mining Corporation of Canada, Limited.

On the contignous claim to the west, No. 9863, in Holloway township, near the southwest corner, on the south boundary line, there is an outcrop of a grey rock resembling a feldspar-porphyry on weathered surfaces. Seven thin sections of this rock were examined under the microscope, and it was found that the rock is too much altered to positively identify. In the meantime, until further stripping is done, or new outcrops found, the rock may be tentatively classed as a feldspar-porphyry. Crushed schistose porphyries and schistose greywackés are often difficult to distingnish.

On the claim contignons to the west, No. 9862, in Harker township, there is, near the southeast corner, an outcrop of quartz-porphyry which is locally known as the "Cooper dike". This rock was said to have been found some years ago by Mr. Wm. Cooper. The quartz-porphyry is in contact with a grey, vaguely banded, siliceous rock resembling certain phases of "iron formation."

The claim immediately to the south, No. 10,084, in Harker township, known as the Manwell, contains an outcrop of a rock resembling conglomerate. The outcrop as about 500 feet west of No. 1 post, and 25 feet south of the north boundary line. The pebbles and fragments are mainly of feldspar-porphyry and green schist. The rock has been sheared and the fragments more or less flattened. It is of doubtful origin, judging from the small outcrop visible.

Cornering at the northwest on the claim referred to in the last paragraph, is claim No. 10,531, in Harker township. Some heavy tranching and shallow blasting has been done by the Teddy Bear Syndicate on an outcrop of rusty-weathering, iron carbonate rock, which is intersected by a new-work of white quartz stringers varying in width from a few inches up to two or three feet. These white quartz veins with a background of the rusty brown rock give the outcrop a striking appearance. A few grains of iron and copper pyrites were noted; and the occurrence of a dull-looking graphite may be put on record.

Six claims to the west, on claims Nos. 11,347 and 11,348, in Harker township, a white quartz vein, averaging about a foot in width, has been stripped from point to point across the two claims. It occurs in porphyrite which is not schistose.

Immediately south of these two claims, on claim No. 11,267, known as the Compton-Pollard, in Harker township, some stripping has been done on a brown schist which is cut by many parallel quartz veins and stringers. The schist contains much rusty-weathering iron carbonate.

Four claims south of the Compton-Pollard, on the Roche claim, No. 11,290, in Harker townshinp, some work has been done. This property was examined by Mr. D. G. H. Wright, who reports that stripping, trenching and a little blasting had been done. There is a disturbed zone 10 or 12 feet wide, striking east 5 degrees south magnetic, which is silicified and impregnated with iron carbonate.

About a mile south of the Seagers claim, a red feldspar-porphyry dike has been discovered at the north end of claims Nos. 11,009 and 11,010. These claims are known as the O'Neill claims, and are in Holloway township. The dike is three to five feet in width, strikes about east and west, and appears to have a nearly vertical dip. The occurrence is about 200 feet south of the north boundary line. The country rock is an altered basalt which is impregnated with iron pyrites at and near the

dike. The dike has been stripped for about 300 feet and a few shots put in. The country rock appears to contain more iron pyrites than does the dike. Gold has been panned in the rusty oxidized material along the dike and in the country rock. A good trail has been cut from these claims northward to the Canadian Mining Syndicate claims.

Immediately east of the O'Neill claims, Mr. P. A. McDermott has done a little work on claims Nos. 11,381 and 11,382, in Holloway township.

South of the O'Neill claims, on claim No. 11,313, in Holloway township, Mr. R. Reid has done some stripping. A narrow quartz vein occurs in basalt.

In Freeheville township, at the forks of the Lightning river, Mr. Dillabough has done a little stripping on the west bank of the river. The rock here is a light coloured grey schist, with a greenish colour on fresh surfaces. The schist has a fragmental appearance due to the presence of light grey lenses of hard siliceous material set in a yellow matrix. Veins of quartz up to 20 inches wide occur parallel to the schist.

Summary

It has seldom been the custom of the Ontario Department of Mines to systematically sample the various deposits which the officers of the Department examine from time to time. Consequently, in sizing up an area, it has been necessary to base an expression of opinion largely on geological structures, although the results of careful sampling by companies or individuals have frequently been available. In the case of the Lightning River area, the writer believes that, at the north parts of Harker and Holloway townships, the severe disturbance and alteration to which the rocks have been subjected are favourable to the deposition of gold ore, and give promise of further discoveries being made. The finding by prospectors of a belt of schisted Temiskaming conglomerate may fairly be judged another point in favour of the occurrence of gold, since both in Porcupine and Kirkland Lake, the gold mines occur in or near these belts of Temiskaming conglomerates. The gold bearing vein on the Seagers claim is but 500 feet distant from an outcrop of Temiskaming conglomerate.

At the south part of Holloway township, three and a half miles south of the Seagers claim, the Meridian claim is a promising prospect, if one may judge from the results of assays shown the writer.

Finally, while it should be noted that the occurrences of gold in the Lightning River area in the prospect stage, the area is unquestionably worthy of further and more intensive prospecting.

News and Comments

BY ALEXANDER GRAY

Lend a Hand to the Hard Hit

Another of those periodic holocausts that have brought desolation and death to the Ontario Northland makes it opportune to call attention to the unwisdom of maintaining forest reserves where there is an army of prospectors and pioneers will seek the shortest route to make their claims. The scene of the latest visitation and the deplorable loss at Haileybury, Englehart, North Cobalt, and elsewhere may be sought as a safeguard against recurrence of disaster; but the cause will still remain while there is dryness in the bush and while parched vegetation may smoulder.

Eleven years ago from the gold mines of the magic land that suffered and the fatalities were all too great. The story of George Wood and his family caught and suffocated in the Wood Dome Shaft; the heroism of Meek and his men who saved women and children in the Dome and the self-sacrifice of "Billy" Moore, the dearest of the Three Men Creek of earlier Porcupine are almost forgotten.

"Billy" Moore in his endeavors to succor the panic stricken, [illegible] would have preserved his own life if he had carried the fugitive who subsequently declined to [illegible] the heroic deed in order to enable [illegible] to procure a Carnegie contribution for Moore's [illegible] family.

Brave men and brave deeds have been in the making of the Northland. Where there are rewards, there are risks. Mankind [illegible]. There is widespread sympathy [illegible] in all this anticipating prosperity and [illegible] after adverse years. Hard as the lessons are, they will spur the Provincial authorities and all others concerned to [illegible] precautions and lend with lavish hands [illegible] the immediate relief of the victims.

The [illegible] of flames, the charred remains, human and material, are distressing incidents in the march of progress. At the moment first aid must come from all sections. Without Northern Ontario other localities might not object to collecting insurance if they were visited by destructive fires. Old Ontario will stand by New Ontario in this hour of need.

Anglo-French Exploration Canadian Holdings

It is so exceptional to have London combinations of mining capital do common-or-garden-sense Canadian business, that it is a small-favors thankfully received matter to note that the Anglo French Exploration Corporation held 9960 Hollinger Consolidated shares; 50,000 Lake Shore, and 5000 International Nickel. "At the market", those holdings now are worth (supposing the market has not been availed of before) approximately $360,000. No doubt the profit obtained from what Hollingers were disposed of, will adequately compensate this mining group for its investigation of Canada and its mineral resources. That a profit is a profit, is a truism, but the capable chiefs of Anglo French might have been better advised had they retained all their Hollinger, taken more Lake Shore, and made another visit or two to the Creighton Nickel Mine. Mr Tyrrell did not do so badly as a "picker". While Canada appreciates the participation of one of the South African groups, even to this extent, "some day", perhaps, London will take its bearings and shape its course somewhat differently. At the moment, New York is annexing most of the good, bad and indifferent business; that is, what London has overlooked, although inquiries from overseas indicate that the Three Kingdoms have quite a collection of "sheep" pastures.

What Makes the World Wag

So accustomed are we to hear that "all mining is a swindle", that it is pertinent at this juncture when the more optimistic have it that Northern Ontario will

rival the Rand, to state that South Africa south of the Limpopo has fared rather nicely from its "swindles". It will be recalled that the discovery of diamonds was denounced by scientists as a hoax originating with land speculators; that the Rand was condemned as a superficial affair. A little gold was produced prior to Barberton and the Rand. A few "vagrant" diamonds were found prior to Kimberley. Yet, to September of this year, the Union of South Africa, the section south of the Limpopo river, had a mineral record of £1,022,000,000. Of that, £717,000,000 is credited to gold; £220,000,000 to diamonds, £54,000,000 to coal, and £23,000,000 to copper. Taking it roughly and in round figures at $5,000,000,000, and not forgetting that this valuation of the diamonds is for diamonds "in the rough", the purchasing power of that grand total of production may convince recalcitrant economists that the wealth of nations has not been impaired by the gold and diamond fields of the sub-tropics. More than three-and-a-half billions in gold, a nominal valuation of $1,100,000,000 for the diamond, and the etceteras, provide an objective for Northern Ontario mathematicians. Forty miles of gold reefs and a few creaters stirred up a good deal of trouble, and more than bubbles. "Every prospect pleases," and so forth.

Retribution Overtakes "Frenzied Finance"

"Tom" Lawson is in "Retreat". The inglorious "hero" of "Frenzied Finance"—of which, by the way, he was not the author—is disposing of his "Dreamwold" (aptly named) estate. Pending the sale, he is cloistered in Maine, declining further publicity, preferring solitude. So the Mills of the Gods have begun to grind. Whittaker Wright, Hooley, Bottomley, Lawson! Next! His career as a mountebank may not be at an end. At least he has evaded the fate of noted derelicts. The moral of it is, that such as Lawson can perform so long, but cannot escape retribution of justice. For a while it seemed as though he would seek to rehabilitate himself through Kirkland Lake areas. The daily press was inclined to hail his advent there as a harbinger of market furore. At present his address is "Somewhere", in Maine!

The Genesee "Find"

It may be as well to explain that the Genesee "find" of silver, in Bucke, is another evidence of intelligent deduction and exploration. Reasoning by the Nipissing Company's experience with one of its veins, where a contact condition proved the theory formed as to ascending solutions at that point, Kirkby Thomas, E. M., with all the data before him, advised that certain work be done. Above a certain depth there is no ore, thus far. Above the contact there is ore, not very wide but carrying satisfactory values. Evidently there is a section, approximately defined, well worth the attention it is receiving, and that is why Mr. Lyman and his people deserve hearty congratulations for their enterprise. The educational effects of the past few years, to say nothing of other resultant benefits, compensate for misadventures in other directions.

Mr. Elfick's Tragic Death

The cruel circumstances under which it occurred made the death of "Harry" Elfick the more deplorable. Found by the shore of the lake he was so fond of, he was the victim of flames which, like wild waters, are ever so ruthless. Mr. Elfick knew his Ontario from Fort William to James Bay, had seen the silver and gold lands of the North succeed the Rainy River and Lake O' The Woods, and had preserved his personal popularity and intimate relationship with the old timers and new ones.

Benefactions of Metal Producers

Were it not for the unrequited enterprise of mine-owners the bathos and phatos of this would be downright harrowing:

Sterling Silver Containers, ½ pint sizes	$42.50 to 59.50
Sterling Silver 14-kt. Gold Inlaid Containers, quart sizes for over-coat pockets	100.00
Quart size, in Sterling Silver,	65.00

Mineowners who make it possible to provide "hip oil." Containers, for universal use if need be, now the Volstead Act has been applied to all vessels entering American ports, are proving themselves to be "an ever-present help". The Luxuries of Life would be unspeakably far removed from both sexes, who find the Containers a vital part of their personal charms. If they must, then drinking "de luxe" is "au fait" only when they can reach for the receptacle and daintily decant the contents.

Some Gold Production Comparisons

To those who prate about the menaces of Mining it hardly is necessary to revive the adage that none dare to climb who fear a fall. For years there were Governments that regarded returns from Mining as perfectly legitimate loot. Sentiment, and with it the governmental view, has changed somewhat, however, and especially in Ontario there is growing appreciation of a Gold Industry that is excelling all others in degree. In connection with this, we have the expressed desire of mercantile interests for greater expenditures in the Northland upon public works, and the optimism pervading official utterances. The Ontario Department of Mines figures for the first half of the year make it more than ever apparent that the gold fields of the province are doing display advertising on behalf of the whole region.

The gold output in the January-June period was $9,845,910, of which, it is permissible to say, $5,866,902 came from Hollinger Consolidated. As the production for the corresponding months in 1921 was $5,761,504, it needs no emphasis to make it positive that the Hollinger alone surpassed last year's total for the half year. That being conceded, it may be observed without incurring resentment that the Ontario 1922 half-yearly record exceeds that of any State in the American Union, excepting California, in all of 1921. During the 1922 first half, California mines and placers sent $7,721,258 in gold to the San Francisco Mint and local smelters and refineries. Here, again, Ontario leads by $2,124,652.

Ontario's production in the six months exceeded by $1,847,410 that of Alaska, which was $7,998,500 in all of 1921. Moreover, to August 12, it is an outstanding fact that Hollinger Consolidated yielded $7,918,694.17, and accounted for $7,644,433.80, against California's $15,061,300 in 1921; Alaska's $7,998,500; Colorado's $7,347,800, and South Dakota's $6,523,000.

Why shouldn't the spirits of mortals hereabout be proud! In each current month Ontario is putting out gold in greater quantity than the State of Utah is annually. While Ontario in 1921 produced $14,624,085, and California $15,061,300, 1922 will notify a wider breach in favor of the Canadian gold fields.

Assuming Canada's 1922 total will be about $26,000,000, Northern Ontario may come within a million of the gold output of California and Colorado combined in 1921.

All of which is by the way.

The Mining Districts

NORTHERN ONTARIO

(Special Correspondence)

Nipissing

Nipissing directors have declared the regular quarterly dividend of 3 per cent, together with a 3 per cent bonus, payable October 20th to holders of record September 30th. This will make a total of 18 per cent paid during the current year and will bring the total disbursements of the company up to $25,303,000. Production at the property is running high and 1922 should be the best year since 1915. For the whole of 1921 the company produced 3,000,000 ounces, while during the first six months of 1922 production amounted to 2,167,000 ounces.

During the week ending September 22nd, Nipissing shipped nine cars containing 704,000 pounds of residues to Deloro. The Mining Corporation shipped five cars containing 118,000 pounds, of which two cars went to Deloro, two to Thorold and one car to Perth Amboy. The O'Brien Mine shipped one car containing to 60,000 pounds to Deloro.

Good Vein at Pancake Lake

The Crown Reserve Mine is understood to have made an important discovery on its Pancake Lake property in the Larder district. The main shaft was being sunk to 300 feet and at a depth of 275 feet a 4-foot vein, carrying extremely high values, was encountered. This appears to be a new vein, which does not outcrop on the surface and channel samples taken across the 4 feet have shown values running into the hundreds of dollars. Officials of the company consider it to be a very important discovery.

The option on the Eleanor Dunkin claims in Gauthier, which has been held by New York interests, has been dropped. It is understood that results to date had not been sufficiently encouraging and that heavy payments were due under the terms of the option.

Another gold discovery has been made in the Township of Catharine on the property of the Van Arnon syndicate. Stripping has uncovered a vein about four feet wide carrying native gold.

Arrangements have been made for the financing of further work on the Hunton Kirkland.

Extensive improvements have recently been completed on the surface equipment of the Canadian Kirkland. The shaft is down 300 feet and will be sunk to the 400 feet, where a level is established.

It is understood that negotiations are under way for the sale or control of the Queen Lebel. This property was recently under option to English interests, but the option was allowed to lapse.

The Harvey Kirkland has about completed its power line to the property from the Montreal Ontario. An electrically driven plant has been purchased and is on the way to the property, so that underground operations should be resumed within a few weeks.

It is officially stated that Porcupine Crown has no immediate intention of resuming milling operations. The new vein near the Hollinger line is being developed at the 500-foot level and a winze will be sunk to 600 feet.

The McEnaney Mine is being unwatered preparatory to an examination and the laying out of further development work.

The management of the Davidson has decided to sink a three compartment incline shaft to a depth of 1000 feet. This is the first incline shaft for any of the Northern Ontario gold mines.

Dome directors have declared the usual quarterly dividend of 50 cents a share, payable October 26th to holders of record on October 6th. No capital repayment was announced, but it is expected that this will be made with the January disbursement.

Plans are under way for the building of a memorial to Benny Hollinger, the discoverer of the famous mine which bears his name. The estimated cost of the memorial is $10,000, and it will be erected on a prominent place on the Hollinger property.

A party of about 40 business men and members of the Toronto Stock Exchange have just completed a trip to Cobalt, Porcupine and Kirkland Lake. It is a good sign for the future of the mining industry in this Province when representatives of important bond and brokerage houses display as much interest as these men have done.

High-Graders Caught

To date five arrests have been made in connection with the theft of gold precipitate from the Kirkland Lake Gold Mines, the two latest being Carl Beswick, solution and refining man at the mine, and John Shaw, who is supposed to have assisted Ed. Deane in disposing of some of the precipitate. Shaw is understood to have broken down under the strain and is now in the asylum. Beswick, Donnelly, Kleiser and Shaw have all made confessions which implicates Deane as being the head of the organization. It is understood that the thefts from the Kirkland Gold run into quite large values, Beswick having admitted receiving approximately $20,000 as his share, and he has already made restitution to the extent of $13,000. Beswick and Deane came up for preliminary hearing in Haileybury on September 30, and it is understood that they will be tried in the near future. The scheme by which precipitate was stolen was a very clever one. Beswick, in addition to being solution man at the mill, had charge of the melting down of the precipitate. In taking the daily samples of the pregnant solution for assays, this was diluted a certain percentage. Beswick keeping track by a system of book-keeping, and a corresponding amount of precipitate was taken. The Kirkland Lake Gold has had a hard struggle to make

ends meet since it commenced milling, and as Beswick admits having carried on his operating for almost two years, the amount stolen would represent the difference between profit and a loss. It is understood that operations were not confined only to the Kirkland Gold, and that other arrests may be made in the near future.

The mystery of the disappearance of a gold brick stolen from the McIntyre Mine in Porcupine about 10 months ago, has finally be cleared up. At the time the brick was stolen a chore-boy at the property was under suspicion. Detectives, however, finally came to the conclusion that he was innocent, and he subsequently returned to his native home in Italy. A woman, who lived in the same town in Italy, wrote a letter to a friend of hers, whose husband worked at the McIntyre, and referred to this man and to his apparent prosperity, and she seemed to think that Ontario must be a very fine place, when a poor man could go there and come back a rich man in a short time. This letter came to the attention of the McIntyre officials, who immediately started an investigation which resulted in the arrest of the man in Italy and two other men in Porcupine, and also in the recovery of a part of the gold.

NORTHWESTERN ONTARIO

Spar Island Being Examined

Many of the older mining properties in the Port Arthur area are attracting the attention of mining operators and investors, with a view to their further exploration and operation. Modern mining practice is so far in advance of that of the old days, particularly in the recovery of values, that an interest attaches to these mines that was absent under former operations. A party of mining capitalists, accompanied by Capt. H. E. Knobel, E. M., are at present engaged in making an investigation of Spar Island. This island forms a part of the Prince Location situated about 25 miles south of Port Arthur on the shore of Thunder Bay.

The Prince Location was the first mining claim taken up on the North Shore of Lake Superior, being located for copper for the old Montreal Mining Company in 1845. It was operated during 1846 and was closed down in the winter of 1846-47. Good results were obtained in both copper and silver. These operations were carried out chiefly on the mainland and consisted principally of tunnelling ad drifting together with a shaft on Spar Island. The expense of carrying on mining operations in those days was excessive. Men and supplies had to be brought from Montreal, up the Ottawa and French Rivers, across Lake Huron, up the Sault River, and around the North Shore of Lake Superior in batteaux to the property.

Since that date some attempts have been made to open up this property, but nothing in the way of systematic development has been undertaken. It has an area of 6,400 acres.

Schreiber Claims Optioned

Lewis Fenning, E. M., of New York, who optioned fourteen claims in the Schreiber district, has made a cash payment of $25,000, and is about to let a contract for 200 feet of shaft sinking. These claims are owned by Messrs. Estall and Boswell of Schreiber.—J. J. O'Connor.

BRITISH COLUMBIA

Premier Dividend

The Premier Gold Mining Company distributed its fourth dividend amounting to $750,000 on the 1st of October. The total distribution aggregates $2,400,000, or a return to shareholders of almost half their investment in nine months. Since the begining of the year the Premier Mining Company has been shipping each month some 3000 tons of high grade ore, running about $80. a ton; 3,000 tons of medium grade, running about $35. a ton; and it has been milling between 3000 and 4000 tons of lower grade ore in its concentrating and cyanide plant. It is estimated that the mine has been turning out ore to the value of $400,000 each month, the high grade and concentrate going to Tacoma Smelter and the medium to the Anyox plant, Granby Consolidated.

Fish Creek Mine to Rival Premier

Dr. Lachlan McMillan, a director of the American Mining & Milling Co., states that the Fish Creek Mine, Salmon River, is going to be one of the "wonder mines" of northern British Columbia. He is convinced that there will be ten properties in the Portland Canal shown to be as important as the Premier Mine.

Big Missouri

The force of men employed on the Big Missouri has been doubled. It is hoped that a road, now under construction, will be completed this fall so that ore may be shipped over the snow during the winter.

Homestake

A. C. H. Gerhardi will have charge of operations in connection with the resumption of development on the property of the Consolidated Homestake Mining & Development Co. Ltd. This is situated at Kitsault Glacier, Alice Arm. There has been a delay of some months because of litigation now settled.

Rich Copper Ore

Some samples of high grade copper ore have been brought from the Horse Shoe Gromp of Claims, McGrath Mountain, Alice Arm. It is said that a vein containing exceptional values has widened from 16 inches at the surface to nearly 3 feet at a depth of 10 feet. Transportation facilities must be improved to permit extensive development.

New Mine for Hazelton District

Dome Mountain mineral prospects, Hazelton District, have been attracting much attention of late. J. D. Galloway, resident engineer, seems convinced that T. J. Jefferson will have a mine. The showings are satisfactory and developments are improving them. On Hudson Bay Mountain the Duthie interests, having purchased the Henderson Property from J. K. Ashman, have placed Captain Turner in charge and high grade ore is being shipped regularly. It is rich ore and is opening up as work continued. At the present rate the investors should soon have their disbursement returned with interest.

Placer Gold Near Usk

A strike of placer gold on Kleanza Creek, about three miles from the town of Usk, G. T. P. Ry, is announced. Two French prospectors are the discoverers. They brought a nugget, thumb size, into Usk and the rush started. The greater part of the ground in the vicinity of "discovery" has been staked. It has been generally understood for some time that a good deal of native gold could be found in the glacial drift of this Creek and some panning has been done before with good results.

Geologist's Report on Cariboo

Dr. W. A. Johnstone, of the Canadian Geological Survey, who has spent the summer in the Cariboo, is quoted as saying that the Cedar Creek Mining Co., operating two rockers on the ground near "discovery", took out $5,985 of gold in six days. He states: "Developments recently have shown the occurrence of pay gravel at several places and particular along the south west bank of the small depression in which the original discovery was made. Somewhat similar gravels have been found at several points on the Platt and Sheridan Claims but it is not quite so rich. There are three rockers at work on the Platt Claims and from two to three ounces per day is being taken. On these claims it is found that the gold is in the gravel and not in bedrock. Prospectors should look for the red gravels beneath the glacial drift and lying on bedrock."

Dr. W. L. Uglow who also had a geological survey party in the Cariboo this summer, states that unless lode mining starts in the hills near Barkerville the camp will die. There is some hydraulic work being carried on but not on a large scale. He thinks that the quartz veins of the district warrant investigation.

T. H. Kerruish, who is developing the Nip and Tuck Mine, has exposed three veins of silver-lead ore, two carloads of which are ready for shipment to trail. The government is building a trail to the property.

Several hundred pounds of samples of gold, silver and copper ores taken from the Whitewater District B. C., are on exhibition at the Chamber of Mines, Vancouver. Returned prospectors state that they have located large high and low grade ore bodies in this comparatively little known section of the Province.

The King Kong Mining Co., holding bonds on properties situated on the north fork of Lemon Creek, Slocan District, and consisting of a small group of business men of Goldendale, Washington, is installing an experimental plant to treat some 10 tons of ore a day. During the summer four miles of trail have been opened up and machinery hauled over rough country, crossing an elevation of 4000 feet. From present indications the enterprise of the investors is likely to be rewarded.

The Wild Horse Dredging Company, using a modern dragline [illegible] has commenced dredging the main channel of Wild Horse Creek. The Gamble Mining Company with holdings adjoining those of the Wild Horse Company has been forced to close down probably until next season. E. W. Watson engineer in charge, explains that most [illegible] of the flumes have been carried [illegible] which underwashed the support [illegible] that work had to cease without the sluices [illegible] out. In all 1000 feet of virgin [illegible] had been piped up by hydraulicing with 3000 [illegible].

J. H. H[illegible] provisional secretary of B. C. Prospectors Association, promises that the organization will be [illegible] to advise the provincial government as to [illegible] legislation needed and that which should be considered at the forthcoming session of the legislature.

The [illegible] Lake Mining Co. has been reported to have [illegible] a large body of low grade ore on its property.

The management of the Drum Lummon Mine, Hartley Bay, expects to be making regular shipments to the Anyox smelter [illegible] Company the next December. Some considerable bodies of high grade ore have been opened up and [illegible] has been installed including a 120 h.p. engine and compressor.

The construction of the new reinforced concrete mill building of the Britannia Mining Company, Howe Sound, is well in hand. Most of the machinery is ready for installation and development continues on the Victoria Claims of the Company with assurance of new large bodies of ore in reserve.

Receipts of ore and concentrates at the Trail Smelter, Canadian Consolidated Mining & Smelting Co., passed the 300,000 mark during the week ending September 21 last. In the lattter period 10,028 tons were received bringing the aggregate for the year up to 306,633 tons. At the corresponding date last year the total stood at 299,510 tons. For the last week recorded the receipts in detail were: Black Rock, Northport Wn., 113 tons; Quilp, Republic Wn., 321 surprise, Republic Wn., 297; Lincoln, Blaylock, 23; Noble Five, Sandon, 63; Bosun, New Denver, 49; Silversmith, Sandon, 199; Standard, Silverton, 43; company mines, 8920.

NOVA SCOTIA

Agreement Signed at Last

It took four days of negotiating in the last week of August to reach an agreement between the Dominion Coal Company and the executive of the United Mine Workers. The general terms were set out and on this understanding the striking miners returned to work. But it has taken over a month to settle the outstanding greivances of the different collieries and the signing of the agreements has been as a consequence long delayed.

It may be difficult to the lay mind to understand that conditions in a coal mine have more to do with earnings than has the price paid to the miner for digging his "darg" of coal. Given good conditions and a fair ton rate the miner has little cause of complaint. But working conditions change so quickly at times that adjustment is always provided for. It is difficult to provide for imaginary grievances, and these, under the agitation stimulated by the executive of the mine workers most of the year, had accumulated in large numbers. Indeed when it came to a discussion of the main features of the agreement, it was found that these were easy compared to the mass of details that already had been waded through. The affixing of the signature of the executive of the mine workers took place on Saturday, Vice President MacDougall being present.

Large Coal Shipments

September coal outputs were large and there were days when the tonnage climbed over the 11,000 ton mark. Shipments to the United States have ceased but the Montreal market will absorb a large amount of coal and by the time shipping ceases that district ought to be well supplied. The coal heap has not yet been all shipped away but brisk business should see its removal very soon. With the Steel Company using more coal and a good demand from outside the outlook to the end of the year is bright.

Education for Workers

In the labor world, Mr. Woodsworth, M. P. [illegible] series of lectures to working men which were [illegible] well attended. Meanwhile the effort to start an [illegible]tional movement among the colliery work[illegible] publicly discussed and arrangements have been made [illegible] a course of lectures during the winter.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclosed ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

CHEMIST, experienced in blast furnace and steel plant work, ores etc., desires position. References. Address Box 521, Canadian Mining Journal, Gardenvale, Que.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical Index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification here given such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

EDITORIAL

Inhabitants of the old world live and thrive in a much more rigorous climate than is found even in the coldest parts of northern Canada, and therefore the climate does not offer any insuperable objection to settlement if minerals or ores are anywhere found in paying quantities. — J. B. Tyrrell—1908.

LABRADOR FIELD FOR ADVENTURE

Time and again it has been pointed out that a large fraction of Canada's territory is unfit for any human pursuit with the exception of mining. Of no part of our Dominion can this more truly be said than of the vast peninsula of Labrador, even the coasts and fiords of which have been only superficially explored. A handful of explorers, principally geologists, have travelled a few of the larger rivers, and have made infrequent traverses of the peninsula—a peninsula a thousand miles broad, from the Straits of Belle Isle to Hudson's Bay, and seven hundred miles deep, from Cape Chidley to the Gulf of St. Lawrence.

What reward Labrador holds in store for the prospector is still a matter of conjecture. The meagre geological data gathered up to the present demonstrate a variety of pre-Cambrian rocks and periods of igneous intrusion that promise well. Dr. Coleman, who examined parts of the east coast in 1915 and 1916, reports areas of rocks of the Keewatin and Grenville series, with later sedimentaries that may be Huronian and Temiskamian in age. Rocks of these ages contain the ore deposits that have made Ontario's mining famous throughout the world. It is only logical to conclude that a similar result will be attained eventually in Labrador as daughty adventurers penetrate its fastnesses and discover its secrets.

To date we publish an account by Mr. William M. Agar, a young Vancouver mining engineer, of his visit to Labrador in the summer of 1921. His photographs, as well as his vivid description, show a land eminently suited to the search of the prospector. The coast is famous for its rugged cliffs on which no blanket of soil or vegetation can rest to obscure the vision of geologist or prospector. Inland the highlands are similarly bare, though the valleys provide sufficient growth of timber for shelter and fuel. Fresh water is available in every valley. Fish are abundant in both fresh and salt water, but the game provides only a precarious food supply.

All told, the features of Labrador drawn by explorers connected by railway are not at all unattractive. If, as is periodically asserted to be the case, there should be found gold placers in the regions left unaffected by the sweep of the glaciers, there is nothing to prevent a rapid and consistent development not only of such deposits, but of whatever other minerals might be disclosed in this least known of Canada's territories.

PORCUPINE'S NEED

Seven years ago the Ontario Department of Mines caused to be printed and distributed a geological report on Porcupine, accompanied by two maps. Since that time, like the immortal commender of Pears' Soap, we have used no other. It is now practically impossible to secure copies of the report or of the more useful of the two maps.

It were a work of supererogation to dwell upon the importance of Porcupine to Ontario and to Canada. Why the Ontario Department of Mines has not, long ere this, given it the attention it deserves, is one of those mysteries that must remain unsolved. Here is a mining camp that has given to Ontario a wealth of publicity and has added to the Provincial exchequer many shekels of gold. Investors on both sides of the Atlantic keenly desire to take their chances in this region of notable performance and of even more promise.

Thus for seven long years Porcupine has played the part of Jacob to the Province's Laban. Jacob, if we remember rightly, had to resort to a very questionable expedient to get what was coming to him. But Laban's role is not one that reflects credit upon the Province.

It is reassuring that the Department of Mines has this year sent Mr. A. G. Burrows, one of the most capable of the younger generation of Canadian geologists, to Porcupine to collect and collate geological data and to supplement the results of the first diagnosis. Unaided, Mr. Burrows should be able to complete his maps and report within the next Jacobean period of probation, another seven years.

Infinitesimal as seven years may seem when contrasted with the geologic eons that Mr. Burrows must deal with, yet to us ephemeral humans it is a long, long time. Most respectfully we suggest to the Premier and his colleagues that they can well afford to appropriate for the work of bringing Porcupine's geology up to date a small fraction

of the amount spent on enforcing the Ontario Temperance Act. The results would certainly be less problematical and most assuredly would create more enthusiasm for our administration throughout the north country.

In all this we wish to state explicitly that we cast no blame upon the Ontario Department of Mines. It is beyond all question that the Department is and has ever been fully cognizant of Porcupine's need. It seems equally certain that it has been rendered incapable of action by reason of inadequate appropriations. There is no other conceivable reason.

We hope, then, that this winter we shall see Mr. Burrows' hands strengthened by a number of competent assistants and that no effort will be spared to make available to the public next summer a thoroughgoing report on the Porcupine of today.

But the Departments' most strenuous efforts will be of no avail if something in the way of a thistle be not placed on or near that part of the King's Printer's anatomy where it will do most good.

GEOLOGIST, PROSPECTOR, AND ENGINEER

More and more our geologists give heed to the practical needs of the prospector and the miner, just as the prospector and the miner gain, year by year, added respect for the utility of the geologist and his deductions. A notable example of this ever-increasing mutual regard is contained in Mr. C. W. Knight's report on the *Lightning River Gold Area*, which appeared in our issue of last week.

In discussing the general occurrence of gold ore in Northern Ontario, Mr. Knight draws attention to its association with either of two great belts of sedimentary rocks of Temiskamian age. His advice to prospectors is, "explore for feldspar-porphyry and quartz-porphyry intrusions in or near these great belts of sediments." So sure is Mr. Knight of the importance of this association of Temiskaming sediments and later intrusives that he is ready to recommend intensive exploration in that part of the Lightning River area where the two rocks occur together, though the actual gold ore-bodies found up to the present are in themselves no more than fairly promising. At the same time Mr. Knight draws attention to another area of Temiskaming sediments 25 miles to the north, that has not yet received the attention it deserves.

A very few years ago the geological conditions that have resulted in the deposition of gold in the various fields of Northern Ontario was completely an enigma. Little by little, the information collected by geologists and engineers in both public and private employ is being pieced together to form a logical whole. Theories once accepted are now discarded in favour of ideas more in accord with observed facts. The present accepted theory is so nearly in accord with fact that it is actually useful in directing exploration and prospecting. Much money is being spent on the score of geological deductions. We hope the event may prove it to be spent wisely.

But geological theories usually fall short of perfection. Our ideas as to the reasons for the deposition of gold in the veins whose output has put Ontario's gold production on a sure footing is still a matter of conjecture. The engineer is not yet able to trust implicitly the deductions of the geologist. It still remains to some extent a case of "where she be, there she be."

We expect to be able shortly to throw added light upon the occurrence of gold in Northern Ontario by means of some geological studies that have been proceeding for some years in the Porcupine camp. The deductions from these studies will not solve all the problems of the miner, geologist and prospector in the gold fields of the north, but we expect that they will at least give rise to some profitable discussion.

ONTARIO'S IRON ORE COMMITTEE

Hon. Harry Mills, Minister of Mines for Ontario, has announced his selection of the following committee to investigate the commercial possibilities of mining iron ore in Ontario: Prof. H. A. Guess, professor of metallurgy, University of Toronto; Prof. H. E. T. Haultain, professor of mining, University of Toronto; Mr. J. G. Morrow of the Steel Company of Canada; Mr. G. S. Cowie of the Mines Department, Algoma Steel Corporation; Mr. Lloyd Harris, of Brantford; and Mr. Hall, of Montreal, the last two to represent the transportation and commercial aspects of the case.

While it is highly satisfactory that the Department of Mines at Toronto has interested itself actively in the iron ore problem in this way, the personnel of the committee, as announced, is distinctly disappointing. It is composed of a group of technical and financial specialists prominent, and even eminent, in their respective lines. Unfortunately, however, not one of them is a specialist in iron ore, though a number are keenly interested in iron ore and have followed closely the developments in the situation from year to year. We were led to believe that the Minister of Mines intended to employ the services of such a specialist. No specialist on iron ore has been included in the committee, and we are disappointed.

The iron ore problem has beset us continuously since our modern iron and steel industry was instituted. Numerous and determined efforts to solve the problem have been made, but so far without success. Many commissions and committees have investigated and reported, without practical result. We proceed anew to observe and to argue, and can continue so to do "ad infinitum" with the same result as before. In the present case it appears that we shall follow the old, beaten track, which will lead us inevitably to the same goal as heretofore—which is exactly the spot from which we started.

There is needed a new plan of attack on this problem. Our iron ore problem in Ontario is not exactly similar to that of any other district, and no course of mere observation of the results in other fields will serve to provide a

solution for our case. The human effort that has been and is being expended in these other fields to ensure a successful issue must be paralleled, though not duplicated, by similar human effort expended on our own problem. A consultative committee is not capable of expending this effort. The committee is, in this case as usual, composed of men well occupied in their special professional work, who can spare only a small fraction of their time and effort for the committee's work. Even if they should stretch a point and neglect a part of their regular duties in favour of iron ore, the problem will not have that whole-hearted and continuous attention without which, we are convinced, even a board of iron ore specialists would confer in vain. The members of the present committee are to be commended for the public spirit that has impelled them to accept this charge; we wish there were some prospect of success more in keeping with their sense of duty to the public cause.

The fact is that, as we have in Canada no iron ore industry, so we have here no all-round specialists in iron ore. If we wish to have the soundest professional advice on our present problem, we must either call in a specialist from outside and give him the facilities and the time to acquaint himself with Canadian conditions, or, on the other hand, we must give to a Canadian engineer or geologist already thoroughly acquainted with the case in Canada an opportunity to study and assimilate the information and ideas that are to be gained abroad. A man thus prepared to study our iron ore problem can logically be expected to find its solution. Anything less than this is trifling with the question.

EDITORIAL NOTES

Two weeks ago we published Mr. Axel Estelle's account of his process for making iron and sulphur from sulphide ores. Today we have Mr. Mason's resumé of the case, with particular reference to the experimental work at Trail, B.C. Soon, we hope, there will happen that happy conjunction of inventive genius, far-seeing executive ability and available capital that is the pre-requisite to the success of any such new commercial undertaking.

We note to-day in another place an occurrence of asbestos in Australia of an unusually high grade both in its quality and in its admixture with the serpentine rock. If further prospecting and development should disclose veins of this high grade ore (20 to 50 per cent. fibre) of larger size than those found up to the present, the district might become a serious competitor of our own in Quebec.

The great electrical development scheme of the State of Victoria, Australia, now under way, is based upon brown coal deposits of vast extent. The Morwell field, where the present plant is in course of erection, has been shown to contain at least 5,000 million tons of fuel. In the Traralgon field, 5,600 million tons has been determined. There are other similarly large deposits of this lignite throughout the State. It seems possible that, as the requirements for electric power on the western prairies become greater, our own lignite deposits in Saskatchewan and eastern Alberta will be put to a similar use, possibly with high-grade fuel as by-product.

HIGH-GRADE ASBESTOS IN AUSTRALIA

In the annual report of the Geological Survey of Western Australia, an occurrence of asbestos is described in some detail. This is at Lionel, near Nullagine, in the northwestern part of the state, 100 to 150 miles from the coast and on the outskirts of the Great Sandy Desert, and just north of the Tropic of Capricorn. The Pilbara gold field is in the immediate vicinity.

Serpentine rocks outcrop at intervals for 200 miles, from Roebourne, on the coast, to Nullagine. At Lionel "the serpentine mass is traversed by silicified bands which stand out plainly like narrow dykes and also by shear zones which are inconspicuous at the surface. In these latter chrysotile asbestos of the highest quality is developed. These asbestos lodes where seen were found to be from two to six feet wide and to consist of innumerable parallel or anastomosed veins divided by narrow lenticular masses of the massive serpentine rock. . ."

"Owing to the rapid variation in the width of the veins it is impossible to give an average length of fibre, but only a small proportion appears to be under half an inch in length. The proportion of marketable fibre in the lodes seen varies from 20 per cent. to 50 per cent. of the whole mass. . ."

"The deposits are mostly small high grade rather than big, low-grade propositions.

"The fibre is superior in quality to any other found in Australia, and compares quite favourably with that in any other part of the world, with the possible exception of the best Canadian.

"Asbestos mining must be regarded as being quite in the initial stages, and the prospects of establishing the industry in the state are very encouraging. A number of the deposits have quite recently been prospected and further search will almost certainly disclose other occurrences."

It is recommended that platinum and osmiridium (worth £16 and £23 an ounce, respectively) which are found only in association with serpentine rock, should be searched for carefully in this area.

THE PROF.

No one could actually be so wise
As that chap looks. His noble brow, his eyes,
Seem made for thought and deepest cogitation
His whole demeanour stirs imagination
To body forth a study and large tomes
His head is twice as large as common domes

* * *

Now he approaches, hitherward doth come—
God bless my soul! The prof. is chewing gum!

J. C. M.

Iron From Pyrrhotite

BY F. H. MASON

S. G. Blaylock, managing director of the Consolidated Mining & Smelting Company, announced at one of the sessions of the Northern Mining Convention, held at Nelson, B. C., on July 3 to 7, that a very pure iron had been made electrolytically in the company's laboratories at Trail from the tailing from the dressing of the Sullivan mine ore.

Though the invention is in only the laboratory stage at the present time, it is one that has far-reaching possibilities. The officials at Trail are not prone to make announcements of the results of laboratory experiments unless there is reasonable hope of commercial achievement behind them, and it is hardly likely that Mr. Blaylock would have made so important an announcement at a public gathering unless he believed that ultimately a commercial process might be evolved from the invention. The laboratories at Trail, too, it is well to call to mind in passing, already have an unusually honorable record of achievement, for in them the electrolytic process that now is turning out 150 tons of zinc daily was conceived, as, also, was the mechanical process now in use for dressing the exceedingly complex ore from the Sullivan mine.

The Sullivan Ore

Sullivan mine ore is a compact sulphide ore, composed, essentially, of zinc-blende, marmatite, galena, pyrrhotite, pyrite, small quantities of other sulphides, and three to six per cent. of gangue. On an average probably more than half of the ore is pyrrhotite. In dressing this ore in the 1,000 ton plant now in operation at Trail part of the galena is removed on tables: the tailing from the tables is ground finely, and most of the remainder of the galena and the zinc minerals are separated by selective flotation, the pyrrhotite, pyrite, and gangue flowing away as a tailing.

The Consolidated Mining & Smelting Company is now constructing near the Sullivan mine, at Kimberley, B. C., the first 1,500 ton unit of a concentrating plant modelled on the lines of the one now in operation at Trail, and it is expected that the first unit will be completed early next year. When this unit is in operation some 750 tons of pyrrhotite, having an iron content of about 60 per cent. will flow away daily in the tailing, and thus some 450 tons of iron will be lost per day. If a reasonable proportion of this iron can be economically reduced from the tailing and put to useful purpose it will be an exceedingly valuable achievement, especially as at the present time there is no iron and steel industry in British Columbia, and both metals have to be brought long distances, the freight charges adding immensely to their cost.

Former Experimental Work

The reduction of iron from pyrrhotite in Canada is not new. At the beginning of this century a large number of experiments were carried out under the direction of Eugene Haanel, at that time director of the Mines Branch of the Canadian Department of Mines, with a view to producing a nickelferous pig iron, from which to make nickel steel, from the Sudbury nickel-copper pyrrhotite ores, thus avoiding an annual loss of three to four hundred thousand tons of iron in the slags. As a culmination of these experiments, the late E. A. Sjostedt produced 168 tons of nickeliferous pig iron in an electric furnace, at Sault Ste. Marie, Ontario. Ore unusually low in copper was selected for the purpose of this test: it was roasted to 2 per cent. sulphur, and reduced by charcoal in an electric furnace at the rate of one and one-third tons per day. The average requirements for the production of a ton of pig were two tons of roasted ore, one and one-half tons of limestone, sixty bushels of charcoal and forty pounds of electrodes, and the resulting pig contained 4 per cent. of nickel, 0.8 per cent. of copper, 0.01 percent. of sulphur, and 0.03 per cent. of phosphorous. The figures are taken from the official report of the experiments, issued by the Department of Mines. At the time, however, metallurgists had such an ingrained objection to the presence of even the smallest quantity of copper in structural steel that no one could be induced to entertain the use of this material, though samples of the pig were sent to the leading steel manufacturers in the United States and in Great Britain. When Sjostedt died he was still working on a process for the removal of the copper from the ore before it was smelted.

G. M. Colvocoresses did an enormous amount of laboratory and small-scale experimental work on similar lines, but he, too, found the copper content of the resulting pig and steel—for he had some pig manufactured into steel—the stumbling block that barred the way to success.

The Benefits of Success

With the perfecting of the flotation process it is probable that the copper content of the Sudbury ore could be so reduced that the amount of copper going into the pig would be too small to be considered detrimental to the metal. Besides, of late years metallurgists have moderated their opinion with regard to the harmful effect of small quantities of copper in nickel-steel. If, then, Mr. Blaylock and his staff at Trail should succeed in evolving a commercial process out of the present laboratory experiments it is likely that the Sudbury district of Ontario may gain as much by the inventions as the Kootenay region of British Columbia.

Mr. J. V. N. Dorr, who has recently returned to New York from abroad, states that he was impressed by the way the Germans are buckling down to hard work. He believes that this "will to work", combined with their well-known precise workmanship and thrift, will go far to rehabilitating their country rapidly.

Dr. Bruce Rose, recently with the Whitehall Petroleum Corporation in India, has returned to Canada and has joined the staff of the Departments of Mineralogy and Geology of Queen's University Kingston.

The Joint Peat Committee have made in their experimental operations at the Alfred bog during the past summer over 5,000 tons of first-class fuel. It has been distributed quite widely throughout the surrounding district at a price of $5.00 per ton, f. o. b. Alfred, Ontario.

The consumption per capita of Portland cement in the United States during 1921 was 0.87 barrel.

The East Coast of Labrador

By WILLIAM M. AGAR

To most of us the name Labrador is synonymous with desolation. The seven hundred mile stretch of rocky, barren coast reaching north west from Cape Charles, in the Straits of Belle Isle, to Cape Chidley, at the mouth of Hudson Straits, blocked with ice for nine months of the year, is less known than the interior of Asia, and the center of this vast area is for the most part wrapped in mystery. During the last thirty years a number of expeditions have penetrated the heart of the country. In 1895 A. P. Low published the results of his explorations in the interior and on the shores of Ungava Bay in the report of the Geological Survey of Canada, Vol. VIII, and in 1903 a party of three led by H. H. Prichard, F.R.G.S., crossed the great interior plateau. R. A. Daly accompanied Dr. Grenfell on the "Brave Expedition" in 1899 and made a reconnaissance of the coast; and Dr. Grenfell, who for thirty years has served the fishermen of Labrador and northeastern Newfoundland, has found time in the midst of his manifold labor to explore and chart much of the northern half of the coast. The best charts of this northern region can be obtained only from him, as he has not seen fit to publish many of them.

A. P. Coleman of the Canadian Geological Survey examined parts of the coast between Mugford and Komaktorvik during the summers of 1915 and 1916. His report, "Northeastern Part of Labrador and New Quebec," Memoir 124 of the Canadian Department of Mines, is by far the best treatise of a scientific nature known to the writer for this particular section. Professor Daly's article "The Geology and Scenery of the Northeast Coast", in the book "Labrador, by Dr. Grenfell and Others", is more general. It is remarkably interesting and very suggestive. The reader should turn to this book for the best available information on the people of "The Labrador" and all phases of their life and occupations. Besides the above mentioned articles Professor Daly has published the results of his personal reconnaissance of nearly the whole length of the coast in the Bulletin of the Museum of Comparative Zoology at Harvard College, Geol. Series, Vol. II, No. 3. Together with this work and that of several other parties and collectors most of the coast remains imperfectly charted and the interior little known.

Land for the Adventurous

During the summer the writer accompanied Dr. Grenfell, Mr. George Williams, and Mr. James Wells of Hartford, Connecticut, on board Mr. Williams' schooner yacht "Nascopie" on a trip along the Labrador coast as far north as Saglek Bay. Shortness of time together with adverse winds or no winds at all prevented our landing at many points of interest and made the collecting of any geological data very difficult. It is hoped, however, that even these sketchy notes, concerning as they do an almost unknown land, will be of interest, and that this article, by putting Labrador in the minds of its readers, may perhaps induce some in quest of an untouched land to explore, new rivers to fish, or a little known coast to cruise, to come in contact with coast scenery unparalelled on the east shore of North America and ranking among the finest in the world.

The Newfoundland government boats, which make a number of trips along the coast from July to October, are small and the accommodation is poor. One boat makes the round trip from St. John, Newfoundland, to Hopedale, Labrador, in roughly two weeks; and a second boat from Hopedale to more northerly ports in ten days. This second boat generally reaches Cape Chidley twice in a summer. The two do not connect.

The steamers skirt the coast and wind their way among the hundreds of islands lying off shore. They offer a splendid opportunity to get a general view of the coast, but they do not enter the bays and fjords that are inhabited. To see these latter a boat must be hired from a white settler or an Esquimau. Owing to the fact that all the inhabitants are engaged in the fishery during the summer months, arrangements should be made beforehand by mail either through the Grenfell Mission hospitals at Battle and Indian Harbors, or the Moravian stations at Hopedale, Nain, and Hebron.

Northwest Shore of Mugford Tickle, Labrador—2500 to 3000 feet high
Note Iceberg in right foreground

A Mountainous Coast

The Labrador coast along the whole of its length consists of a succession of bays and barren, rocky headlands, with generally a fringe of islands of diverse sizes lying off shore. This island border varies in width from nothing to more than twenty miles.

South of Ford's Harbor, at the mouth of the Nain Run, the altitude of the shore line and islands lies between two hundred and eight hundred feet, with the Mealy Mountains in Hamilton Inlet, two thousand feet high, and the range back of Cape Harrisson, two thousand two hundred feet high, as the only conspicuous elevations. North of Ford's Harbor the general height averages well above one thousand feet and a succession of mountain ranges rise up out of the sea between three thousand and six thousand feet.

Icebergs are a striking feature of this coast. All the way from northern Newfoundland to Cape Chidley the towering pinnacles and the rectangular forms of the many shaped "bergs" line the seaward horizon and drift close inshore on their steady journey southward. They are most numerous in the late spring, though some remain throughout the short summer as sentinels, guarding the silence of that land and giving a suggestion of wonders to be seen.

General Geology of the Coast

The rocks of the Labrador coast are chiefly highly contorted Archaen gneisses and schists composed of metamorphic sediments, with a striking lack of limestone, and intrusives of granitic and syenitic nature with local masses of anorthosite. This complex is intersected by numberless intrusions of pegmatite which appear to be strangely unproductive of well crystallized minerals.

Unmetamorphosed or very slightly metamorphosed gabbro and basalt intrusives are very common at some points and are sometimes followed by a second series of granitic pegmatites.

These and the slightly folded Pre Cambrian sediments of the Kammajet Mountains complete the rock types.

The Quaternary ice caps have left many marks of their presence. They will be discussed further along.

Battle Harbor, near the southeast tip of the penninsula, is a small settlement lying along the shores of a narrow tickle between two islands. These islands are composed of various gneisses. The smaller one, Battle Island proper, is intersected by a series of serpentinous pegmatite dikes and veins composed almost entirely of quartz and pink felspar with rare tabular crystals of hematite. These dikes vary from several feet to a fraction of an inch in width, the smaller ones in particular have very sharp boundaries and form wavy, pink lines in the dull grey gneiss.

Battean Harbor lies about forty miles north of Battle. There are many rocky islands hereabouts lying from 100 to 300 feet above sea level. They are very rough though slightly rounded by the ice and the stoss and lea topography is developed on a large scale. The country rock is a contorted injection gneiss cut by many quartz and pegmatite dikes and by a later coarse-grained, unmetamorphosed diabase. This latter occurs as large dikes roughly fifty to two hundred feet thick and is in turn cut by a few pegmatite dikes. There are several wave-cut terraces on the outer shore about one hundred feet above the present sea level.

Indian Harbor, about 120 miles north of Battean, is a narrow tickle between two islands off the mouth of Hamilton inlet. Many unmetamorphosed basic dikes are a prominent feature here. The high rock back of the Grenfell Mission station is a dike which, when viewed from the proper angle, shows the almost perfect profile of an Indian head.

The Ancient Peneplain

The distance from Indian Harbor to Hopedale is 140 miles. Many great bays, nearly unknown, lie between these points. Canairiktok, lying about three fourths of the distance to Hopedale, is a broad, winding bay twenty miles long. Canairiktok River, for seven miles above the bay, flows between high, level topped sand terraces, the remnant of a former flood plain, which ends in a triangular, flat-topped island in the mouth of the stream above the now growing delta. At the head of this seven mile stretch, which is an estuary, the river tumbles forty feet or more from the old level to the new. The region back of this bay is a rolling, rugged land with bare hilltops lying between one thousand and fifteen hundred feet above the sea. The old plateau surface can be made out fairly easily in the accordant summits of the hills. It is cut by numberless valleys with a dense growth of spruce and tamarack and hundreds of lakes and ponds.

The next bay to the north, Aglatok Bay, is similar to Canairiktok but somewhat narrower. The river at its head flows from out a long stillwater behind three precipitous mountains which raise their bare summits one thousand to eleven hundred feet above its banks, and seeks the level of the sea over a series of falls and rapids. The river deposits most of its load at tidewater and is shallow and sandy there. The banks are well clad with spruce and are composed of a pink granite.

Labradorite

Eighty five miles north of Adlatok lies Ford's Harbor on an island off the mouth of the Nain Run. The famous labradorite locality is on an island a little way up the run. It is here that the island barrier is thickest. The distance from Nain to the outermost island is nearly one hundred miles. These islands vary from a mile or two in diameter to a mere projecting rock and many sand dunes are found on some of those a few miles from the open.

Falls of the Canairiktok River, Labrador, from above, showing about Five Miles of the Estuary

The absence of sand and fine silt along the open coast is marked. The big rivers all empty into the heads of deep bays and naturally deposit their load far from the coastwise current, but whatever of fine material reaches the coast from these or the smaller streams which often fall directly into the sea, or is formed there by attrition resulting from the pounding of the surf, is carried off to be deposited somewhere further south.

A Rising Coast Line

Two things militate against the formation of any fine debris on this coast. First, the rivers generally flow through vast stillwaters consisting of lakes and sphagnum bogs before plunging over the edge of the plateau into the bays, and thus are singularly free from any mechanical load. The sand at the mouths of many may then be a reworked morrainic material and belong to a previous period of erosion. This is suggested by the composition of the river flood plains at Saglek Bay to be mentioned further along. Secondly, the coast is rising at a considerable rate, and this always exposes fresh rock to the action of the sea.

North of Ford's Harbor the height of the coast increases rapidly. The first marked elevation is reached at Port Manvers where Mt. Thoresby rises two thousand seven hundred and thirty three feet from the water level. It is composed of a dark rock, probably basalt or gabbro.

A little way north of here the Kiglapait Mountains (Esquimau for sierras) which, according to Daly, are a large mass of gabbro, parallel the westerly trend of the coast for a distance of thirty miles. A beautiful view of this rugged range can be obtained from the summit of Dawes Island. These ragged mountains have never been climbed nor, as far as we could ascertain, have their bases been explored. Their heights are not accurately known but they certainly rise between three thousand and four thousand five hundred feet, if not more. The lower slopes are rounded by ice but the summits are unglaciated needles of rock.

From this same point the first view of the Kaumajet Mountains was obtained. Their summits, covered with fresh snow, showed now over, now between, the clouds which drifted across the northern sky. It is a common thing in this country to have a clear sky and bright sunshine a few miles inland, while at the same time the islands off the coast, the towering capes, and the mouths of the many bays are wrapped in fog. Under these conditions the temperature varies many degrees between the fog-covered coast and the sunny land within. The east wind may drive the fog inland, but it is absorbed by the warmer air as fast as it advances.

The Hills Round Mugford Tickle

The Kaumajet Mountains, of which Cape Mugford is a part, rise as sheer cliffs and castellated towers between two thousand and four thousand feet high. They are composed of nearly level or slightly tilted sediments made up of normal land wash interbedded with tuff and breccia and underlain in part by a pillow lava flow, the whole resting upon the truncated surface of the contorted gneisses. Great talus slopes lie at the base of sheer precipices one thousand feet or more in height. Snow caps the higher summits most of the year and milky white streams tumble over the cliffs, leaving a shining trail of ice on either side.

Mugford Tickle is bounded by two high precipices. The northwest shore is the higher; and back of an eighteen hundred foot ridge which is hardly more than halfway to the summit, there lies an immense, barren cirque with thousand foot vertical walls. A few small lakes in this rock basin drain into the tickle over a three hundred foot cliff.

On leaving the tickle and sailing north the majestic summits of the Bishop's Mitre, three thousand five hundred feet high, and the four thousand foot dome of Brave Mountain come into view. The Bishop's Mitre has two peaked summits divided by a narrow chasm which cleaves the mountain most of the distance to its base. Two jagged rocks, rising nearly one thousand feet, stand at each side of the base of the cliff and help one to gauge its height. On the seaward side the thousand-foot tops of the many pointed Nascopie Island complete the view. This is one of the finest bits of scenery on the coast and, because of the form of the mountains, it stands in striking contrast to the smooth rounded and contorted outline of the shore or to the [illegible] of the Kiglapait.

A Natural Tennis Court

One day's sail north of Mugford, past many high capes, lies the Esquimaux settlement of Hebron. The land here is about [illegible] high. Vegetation consists only of mosses, berry bushes, grass, and the dwarf birch. The slopes and summits of the rolling mountains are covered by loose-lying cobbles four or five deep and frequent large-sized boulders. Here and there at the base of a cliff there is a pavement of rock slabs, which is nearly smooth enough for the surface of a tennis court. Coleman * has mentioned such pavements in the Nachoak region. He suggests that they owe their origin to the movement of deep snow under pressure; but their position here suggested their formation at the base of torrential waterfalls which existed possibly only during the melting of the snow in the spring of the year.

Twenty miles north of Hebron Cape Uivuk stands guarding the entrance to Saglek Bay. This is a one-thousand foot cliff composed of contorted grey gneiss cut by a number of perpendicular basalt dikes. An excellent photograph of this is to be found in Coleman's * report.

Saglek Bay

The outer part of Saglek Bay contains many islands arranged in two groups, and is surrounded by rugged mountains. It is impressive enough, but the true marvels are hidden behind the narrows.

When this point is reached, sixteen miles from the sea, an open, though rugged, arm makes away to the south,

North Shore of the Narrows of Saglek Bay, Labrador. Approximately 3500 feet high

and the main bay shrinks to a bare mile in width and winds inland at the foot of gigantic cliffs, which raise their turreted summits to between three and four thousand feet, almost vertically.

The narrows once past, the fjord splits into three parts. Two short arms pointing to the west and northwest are narrow chasms bounded by vertical walls well over half a mile high. A third runs for twenty miles to the southwest between nearly parallel, level-topped walls fifteen hundred feet high. It is less than a mile wide and ends in a three towered mountain, three thousand six hundred and fifty feet in elevation, which falls away on either flank to a flat gravelly river valley.

The sheerness of the walls, the vast, half revealed cirques, the hanging valleys, the tumbling, feathery cascades—each with its miniature canyon—the deep blue water, the bare brown walls, and the vivid sky above make a never to be forgotten scene of true magnificence. The cliffs all have talus slopes at their bases. These form a narrow strip of beach which slopes gradually for fifty feet beyond the water line and then plunges steeply into the depths of the fjord.

Even the bottoms of the valleys are nearly barren here, for they are beyond the northern limit of trees on the east coast. Grass and moss are common, and patches of willow five feet high grow in the protected hollows. Creeping

* Coleman, A. P. Newfoundland [illegible] Labrador and New Quebec. Canada Dept. of Mines, Memoir 129.

birch, alder, and berry bushes, reach up the ravines and make a thread of red and green in the uniform brown tabric of the moss. Even these cease as the altitude nears one thousand feet, and then the yellow brown mosses and grass alone bind the surface debris together.

The upper rocks are riven by frost, and tumble down to make great talus slopes of angular blocks.

The Inland Hills

The high, desolate plateau lies at an elevation of between three and four thousand feet. It is really the remnant of a former plateau and is an endless repetition of rocky summits and chasm-like valleys. These summits are either rough peaks of bare rock or rounded, nearly flat-topped domes covered by a debris of angular fragments of stone. Fields and patches of snow break the monotony of the scene and light and shadow alternate over mountain and valley, softening their harshness. When the sun is low this desolation is touched with a wild beauty by the pink and purple lights. At night the calm water is black under the shadow the cliffs, but in the center it reflects the brilliance of the stars and the pale tints of the aurora which waves through the sky like a filmy, wind-blown curtain.

The two rivers that empty into the bay come down through long, deep, U-shaped valleys and meander over gravel plains whose composition is too heterogeneous to be that of a river flood plain. Rather it is that of partially re-worked glacial material. The fine sand is being washed out into a composited delta, with very steep foreset beds. The emerging topset beds mingle with the old morrainic detritus.

The rock forming the mountain at the head of the bay is a garnet gneiss with irregular intrusions of a quartz-feldspar-garnet rock. Small garnets are an integral part of the gneiss, but many large ones, up to six inches in cross section, accompany the later intrusion. This appears to tally with the "grey or pale pink gneissoid rocks, mostly characterised by the presence of garnet" which Coleman* says "extend over a large part of the Komaktorvik and Nachvak regions."

The narrows are cut through a series of folded sediments. We did not have an opportunity to study these. They may or may not be similar to the sediments of the Ramah series on the south shore of Nachvak Bay.

The broken rock of the plateau is unlike the covering of rounded boulders so common over much of the lower land farther south. Those have been moved a considerable distance — often many miles — by the glacial ice that overran that land during the last great ice age. They are true erratics. The broken, angular debris, on the other hand, has been torn from the parent rock by frost and other agent of weathering. It is itself very deeply weathered and is either in place or has merely moved down hill under the influence of gravity.

Higher Levels Unglaciated

Judging from the evidence of this plateau, that of the upper reaches of the Kaumayet, and the unglaciated aspect of the Kiglapaits, it would seem as though all the high points of Northern Labrador must have projected through the glacial ice cap as islands of rock similar to the present day "Nunataks" of Greenland.

Some localities along the coast show poorly preserved chatter marks and glacial gouges. These do not show any regular trend for the ice and are most likely the result of the final action of local valley glaciers that remained after the disappearance of the continuous ice cap.

* Coleman, A. P. op. cit.

In measuring the height of the land about Saglek Bay and at other points along the coast a small aneroid altimeter was used. After establishing the height of any one point a Brunton Pocket Transit used as a level gave the approximate relative heights of other points within a few miles of the observer.

A Field for Exploration by the Initiate

This great coast, now almost unknown, will doubtless be the scene of fishing and hunting expeditions in greater number in the near future. Our party fared pretty well in this respect, but it must be remembered that there are years when game is plentiful, and others when it inexplicably disappears. These are times of death and hardship to the few roving Indian bands that compose the sparse population of the interior. These years cannot be foreseen and parties going inland should have a supply of food for every man for every day, as advised long ago by A. P. Low. In this manner the danger of a "lean" year will be avoided and the kind of disaster that overcame Hubbard's* ill-fated expedition need not be encountered.

Labrador is always grand and often beautiful. Its amazing coast and great silent interior call to the explorer, but the wilderness is quick to punish man for his mistakes; and here, as elsewhere, it must be approached with a full knowledge of the difficulties to be met, a knowledge which can best be gleaned from the records of the few who have gone before.

* The discoveries made by and the insuperable difficulties and hard luck encountered during this expedition have been admirably recounted by Dillon Wallace in "The Lure of the Labrador Wild."

WORLD PRODUCTION OF COAL IN FIRST HALF OF 1922

In spite of the great strike in the United States the world's production of coal in the first half of 1922 was greater than in the corresponding period of 1921. The total output in the six months January to June, 1922, according to reports collected by the United States Geological Survey, was approximately 568,600,000 metric tons.

Continued for twelve months, this rate of output would yield a total of 1,137,000,000 tons. Settlement of the strike in this country insures that world output in the second half of the year will be greater than the first, but even so, it seems unlikely that the total for 1922 will much exceed 1,180,000,000 tons. This is an increase over 1921, but a decrease of nearly 140,000,000 tons from 1920.

No other fact indicates more clearly the world-wide industrial depression of the past year and a half. In comparison with the last year before the European War, the present year shows a decrease of 12 per cent. and this in spite of the fact that in pre-war years the world consumption of coal was increasing at the rate of 38,000,000 tons a year.

Comparison of the figures for the first half of 1922 with those for the corresponding period of 1921, shows an increase for most of the countries of Europe. The increase was greatest, of course, in the British Isles where the mines were closed by a strike, in April, May, and June of last year.

The Canadian Ingersoll-Rand Company have lately issued Bulletin K-701, *"Circo" Steam or Air Hoists*; and Bulletin K-702, *"Circo" Electric Hoists,* describing in some detail all these classes of hoists, almost all of them applicable to mining work. The Bulletin will be sent, on application, to those interested.

A Budget From New York

by KIRBY THOMAS

C[illegible] the Electrical Industries

C[illegible] to being one of the best conductors of [illegible] of all the base metals, has also qua[illegible] and strength which make its general use [illegible] of present day electrical applications a [illegible]. Statistics show that for the decade [illegible] 1914 more than half of the world's yearly output of [illegible] consumed in the electrical industries. During the war the special military requirements for copper and the abnormally high prices for it that prevailed [illegible] the practical suspension of any new large [illegible] installations for industrial or commercial purposes had the effect of greatly curtailling the large [illegible] market for copper. But now conditions [illegible]. The market price for copper has declined to [illegible] the average for the pre-War decade and there are [illegible] surplus stocks of copper available for all industrial [illegible]. However the demand for copper in the [illegible] is as yet comparatively small, for there [illegible] no large extension of power or transportation [illegible] owing to the continued bad conditions of [illegible] and industry generally, and existing electrical [illegible] have been at a low ebb of operation. That [illegible] is slowly but certainly changing must be recognized. The return of normal, or good, business [illegible] in this country, and the betterment of business [illegible] will have the effect of increasing greatly the [illegible] for copper in the electrical industries. Already many hydro-electric and large steam electric power installations are planned, and their need is today greater than ever before. Their realization only [illegible] favorable or better conditions for their financing, which conditions must come sooner or later.

The [illegible] methods of generating and of long distance [illegible] of electrical energy also have been greatly [illegible] recently. The number and extent of these are [illegible] realized by those not connected with the [illegible] developments. A western electrical [illegible] estimated that in the next decade there will be [illegible] western states electric plants with a [illegible] of 2,800,000 horse power, and that these will [illegible] about 280,000,000 pounds of copper. The [illegible] for the North Atlantic states [illegible] a government engineering commission [illegible] electrical installation of 17,500,000 [illegible]. A California power company has recently [illegible] 10,000,000 pounds of copper for [illegible] being built. Large eletrical installations are [illegible] in the Southwest in connection with the [illegible] project. Several of the large east[illegible] have definite plans for the elec[illegible] of their lines where traffic density [illegible]. In Europe and in South America [illegible] development programs are dependent [illegible] the upturn in the world's [illegible].

[illegible] prospects for the restoration of the [illegible] demand for copper, and on a scale greater than [illegible] that copper mining is not going [illegible] and they portend a demand that [illegible] resources of the country's large [illegible] of which are today idle or operating [illegible] scale. The prospect of a return of normaley in the copper industry is a matter of great concern, not only to a large number of investors in copper mining stocks, many of which stocks have heretofore been consistent dividend payers, but to the many once-thriving communitites in the west, and in the Lake Superior region, dependent on mining activity, and also in the far reaching collateral business connected with the production and industrial applications of copper.

"Makings" for Cigar Lighters

The matchless cigar lighter seems a simple thing enough with its rough-edged metallic circle emitting the shower of sparks that kindle the oil-saturated wick, or tinder; but when the scientists do the talking, it is quite wonderful after all. The sparking wheel is made of a pyrophoric alloy, according to these same scientists, and the principal ingredient is a rare element called cerium. This material, mixed with about 20% of iron, has the peculiar quality of oxidizing, or burning, when struck or scratched. This property is not confined to cerium and its alloys; the old fashioned use of flint and steel was based on the same phenomenon, and the sparks from the steel of the shoe of the running horse is another example. But the cerium alloy is more effective and certain than the flint and steel, and hence its wide use for the now common cigar lighters, and for the automatic lighters for the miners' acetylene lamps.

Cerium is found in Brazil, and also in the Carolinas, where it is associated with another rare and useful element, thorium, from which is made the incandescent gas mantle. Cerium has been obtained chiefly as a by product from the thorium treatment operations. For a long time the demand for it was limited, and large stocks were accumulated. These, however, were all used during the war, to supply the armies with lighters, and the increasing requirements of the material for its pyrophoric qualities have made it nessary to search for new sources of supply.

Back in 1893, a geologist engaged in scientific work for the Canadian government, made a record in his voluminous notes of the occurrence in a remote locality of northern Quebec of a granite ledge, in which were interspersed plentifully crystals of a rare mineral called allanite, a mineral that contains the element cerium and also didymium, lanthanum, and other rare elements and some thorium, a radio active element. Recently the Canadian Geological Survey has made an investigation, based on the casual record of this observing geologist. The ledge was found far north in Quebec, about fifty miles from Grand Mère in the division of Three Rivers, and there was disclosed what appears to be an extensive deposit of this now valuable mineral. Crystals of allanite, 6 inches by 4 inches by 2 inches, spotted the granite ledge over a large area, and clusters and groups of smaller crystals were found abundantly. It is estimated that the rock may yield better than [illegible] of allanite and that the extent of the deposit is practically unlimited. Thus the purely scientific observations of the geologist, made without [illegible] knowledge of any possible commercial application, have become after many years the means of discovery of a valuable natural resource.

The Mine Explosion on Vancouver Island

FINDING OF THE COMMISSIONER

The cause of the explosion of August 30th last in No. 4 Coal Mine, Cumberland, Canadian Collieries (D) Ltd., in which eighteen lives were lost, a detailed description of underground conditions before and after its occurrence, and several recommendations are feautres of the report of Mr. George Wilkinson, former Chief Inspector of Mines for British Columbia, who was given a special commission by the Hon. Wm. Sloan, Minister of Mines, to investigate and submit a report upon the disaster. Of those fatally injured on this occasion it will be recalled that two were British subjects, one Russian, six Japanese and nine Chinese.

In a few words, Mr. Wilkinson finds that the source of the trouble was a flash or open sparking caused by an arc in the electric trailing cable at the connecting socket used in connecting this cable with the main electric circuit. This electrical system was used to furnish the power necessary for the operation of a coal cutting machine. The latter was of a type approved by the United States Bureau of Mines for use in gaseous mines.

Regulations Recommended

"After giving the matter very careful consideration" says Mr. Wilkinson "I would recommend the adoption of the following rules as part of the Coal Mines Regulation Act, and would further suggest that the whole question of the use of electricity be fully investigated by the Department of Mines and, if possible, definite conclusions reached with reference to the permitted use of this power underground in coal mines."

Following are the recommended rules:

(1) No terminals of main feed lines shall be located nearer any coal face than 50 feet.

(2) When blasting is being done the current shall be cut off and the cables made dead in that vicinity, and the current shall not be switched on again until blasting is finished and the places are examined and pronounced safe and the cables have been examined and found free from any damage which may cause defects.

(3) All permanent electrical installations and transforming stations underground shall be made fireproof.

(4) All switches and terminal connections shall be protected or enclosed so as to prevent accidental contact by persons, and danger from arcs or short circuits, fire or water, and where there may be risk of igniting gas, coal dust, or other inflammable material, all parts shall be so protected as to prevent open sparking.

(5) All cables used underground shall be covered with insulating material, and where high pressure voltage is in use, properly armoured cables of standard thickness shall be used.

(6) All trailing cables shall be of properly armoured construction whatever voltage is used.

Confidence is expressed that these rules will give additional margin of safety. Rules 1, 2, and 3, it is asserted, should be put in force at once. As for Rules 4, 5 and 6, it probably will require three months to secure and instal the armoured cables and other material required to make them effective.

Mr. Sloan already has taken the action necessary to give these recommendations the effect of law. Orders-in-council have been passed and from October 2nd the rules enumerated are a part of the "Coal Mines Regulation Act." operators of Collieries in the Province have been so notified and Inspectors of Mines have been given instructions accordingly.

Carelessness with Electric Cables

The electric cable to the coal-cutting mahine was damaged by flying rock from a brushing shot, and the resulting arc ignited a small pocket of gas.

In the course of "general remarks" the Report reads: "The unfortunate loss of life in this case is to be regretted. It was a small explosion to take such a heavy total and it was a combination of circumstances which made it do so. Occurring on a longwall face it naturally brought a number of men in the path of the flame in a short distance. Owing to the most of these men being engaged working in the face, and the seam not being very high there was no way of escaping. It is the opinion of the writer that if the current had been cut off the cable while the shot was being fired there would have been no explosion and it was an error of judgment on the part of the fireboss in not having this done when the terminals of the feed cables were in such close proximity to the shot. It would have been better if the terminals of the main feed line had not been located so close to the face and fixed flameproof terminal boxes had been used. This does not suggest that it would not have been possible for an arc to be created if the above named terminal boxes had been used because if the blow had been of sufficient force to draw the bare end of the connecting cable clear of the insulated material it may still have created an arc but the chances of doing so would have been less. It is questionable owing to the amount of gas being given off and the peculiar conditions existing if it would be wise to continue the use of electric mining machines in this section. At present there are no specific regulations governing the use of electric power in mines of British Columbia, this power having been used only to a limited extent. No doubt the use of this power will be increased in the future when electrical development takes place in the Province. Electric power is used extensively in the United States and great Britain in and about Coal Mines.

Appliances all of Approved Types

"These electric coal cutting machines were installed by the Canadian Collieries (Dunsmuir) Ltd., nearly seven years ago, and the recent accident is the first recorded. While approved by the United States Bureau of Mines, the standard of safety must be judged by the weakest link. The weakest link in my opinion is in cables and connection in close proximity to the working face."

Mr. Wilkinson states it is deplorable that this accident should occur after the efforts of the Mines Department and the management to safeguard operations. He continues: "Edison electric safety lamps are used throughout with the exception of the few flame safety lamps for testing purposes. No blasting down of coal was permitted in this section, and most of the brushing was done without blasting, it being only resorted to in places where the rock was so hard it could not be lifted without it. Only permitted explosives were used.

It is hard for the higher officials and the Inspectors to watch every detail in a mine of this size. The ter-

minals of the main lines are being moved from time to time, and this detail comes more under the control of the under officials. There were plenty of electricians employed to carry out the work, and also a sufficient number of certificated officials employed to supervise all work. In addition to the large staff of regular officials, there is employed a safety Engineer who holds a First Class Certificate of Competency. He constantly patrols the works inside and out, checking up and pointing out any defect he may notice that may cause accidents."

Mr. Wilkinson is of the opinion that the point of ignition was a cavity in the roof near the face of No. 1 slant. "This" he states, "yielded sufficient flame by being fed with gas from the crevices to reach No. 3 counter roadway where explosive gas was known to exist. This explosive gas was connected up with the various crevices and cavities in the roof. Once ignition took place a suction would be created which would draw the methane from the crevices, feeding the flame until this point was passed after which it would die out."

Arc Ignites Gas in Cavity

Commenting further on the cause of ignition it is stated that the main three phase circuit was carried up No. 1 slant, No. 4 level to a point approximately 16 feet from the coal face and about 4 feet from the end of the brushing. The top cable was about 17 feet below the roof line and the bottom of the cavity and the lower cable was about three feet above the top of the brushing. He speaks again of the breaking of the wire by flying rock following the firing of a shot and asserts that there must have been considerable flash from the arc so created. The break occured only about 2 ft. from the cavity. There were only two possible sources of ignition, one the arcing of the electric circuit and the other flame from the explosive in the shot. The shot was a good one, he says, and the chances that any flame resulted are very remote. It was some 8 ft. from the cavity while the junction point of the trailing cable was only about 2 feet distant. He adds "*from conditions as seen after the explosion I have to conclude that actual ignition must have been from flame or sparking from the electric circuit.*" Reference is made to the evidence of the fireboss at the inquest to the effect that he had carefully examined the place before firing the shot and found no gas and also that he had examined the cavity in the roof with similar results. Mr. Wilkinson expresses doubt of this. It is possible, he says, that this was done and that there was a change between the time of examination and the firing of the shot. However assuming the cavity was clear, so far as could be ascertained from the fireboss' lamp, there was no doubt gas above this line in the cavity.

Imply Ventilation

Dealing with the ventilation it is stated that on the 26th day of June there was 22,000 cubic feet permitted for [illegible] and 8 mules, on the 25th day of July 30,000 cubic feet permitted, and the 11th day of August 24,000 cubic feet for the same number of men and mules. The amount passing is nearly three times that required by the "Coal Mines Regulation Act" under normal conditions, according to Inspector Jackson. Since the installation of a booster fan, electrically driven, for augmenting the ventilation the quantity passing in this district has been increased some 6,000 cubic feet per minute.

Officials of the Canadian Collieries are said to have been faced with unusual difficulties in the ventilation of the mine, which is of large extent, having been operated for 30 years or more. Large extraction of pillar areas in the earlier days of operation, without any thought for the future, has resulted in a problem for solution by the present day management. Mr. Thomas Graham, the Superintendent, and his staff have made many improvements in the past five years. Among these are: "the building of permanent stoppings with a gunite finish in cement practically throughout the mine on main airways. The installation of a second fan of the Sirocco double inlet reversible type with a rated capacity of 200,000 cubic feet per minute against a 6" water gauge. The construction of a new separate return airway through the old works practically the whole length of the slope."

NEW CALEDONIA NICKEL

(Translated from "LE BULLETIN DU COMMERCE", Nouméa July 28th., 1922.)

Société le Nickel

A meeting of the shareholders of this company (the largest miner and smelter of nickel ore outside of Canada) was held on the 8th May, 1922. Mr. Tambour, president of the Board of Directors, presided, assisted by Messrs. Puerari (of the firm of Miraband and Co.) and Albert Ducros, scrutineers. At the opening of the meeting holders of 24,594 shares of stock, or their proxies, were represented.

During the past fiscal year, which ended the 30th June, 1921, the company has suffered from the effect of an economic crisis. Although during the first months the tonnage of sales shows a slight increase over that of the preceding months, at the beginning of January it dropped 50 per cent. and continued to decrease during the following months, owing to the dullness of the metal markets.

In order to curtail expenses certain steps have been taken by the Directors which have already produced good results, notably the concentration of the management at Thio and the removal there of different departments which had been up to that time located at Nouméa. The smelter has operated continously, but under most unfavourable conditions owing to the high cost of fuel and the rate of exchange in Australia.

In Europe, the furnaces in England have remained completely closed down. The refinery at Havre has been working uninterruptedly, sometimes at full capacity, sometimes with a reduced output. The mill at Iseriolin, after being remodelled, has resumed operations.

One of the greatest difficulties met with in connection with the work of the company has been the recruiting of labour. As a sufficient number of native workmen could not be obtained it was necessary to import men from Indo-China. The latter are well adapted to New Caledonia conditions and it would seem as if this venture should help to solve the problem of labour in our Pacific colonies.

The "Société le Chrome", grantee of waterpowers in New Caledonia, have intrusted their development to the "Société le Nickel". It is estimated that in two years the electric refining of nickel ore in New Caledonia will commence.

The meeting passed unanimously the financial statement for the fiscal year just closed, the statement showed a credit-balance of 1,105,112 francs.

News and Comments

By ALEXANDER GRAY

Plea for Mining

As a rhetorician, Ex-Governor F. T. Congden of the Yukon, who is logical withal, told some wholesome truths to the Reform Club of Montreal, about the indifference displayed toward Canadian Mineral Industries, Mining Laws and the Geological Survey. Of course eloquence has its indiscretions. Over-statement, though, is a pardonable element in propaganda. Mr. Congden, at any rate, stirred up those present on the occasion; it may be his remarks will arouse the Government of Quebec to a fuller realization of the importance of the Department of Mines and the necessity for a more aggressive policy.

It is inadmissable that "anyone who knows something about minerals is of the opinion that there is more gold in Quebec than in Ontario"; Mr. Congden was a trifle too flamboyant in that respect. Yet if the Quebec Department of Mines is allowed to prove it everyone that is "anyone" will applaud.

Advocating the cause of the Geological Survey, bespeaking for its members a more dignified and remunerative status, Mr. Congden urged scientific prospecting and simpler language in reports. To him Dawson's documents were admirably "simple and intelligent". However, elementary Mr. Congden would have the Geological papers, he could not accomplish his purpose by putting the Survey upon a kidergarden basis. Universality of mining laws might not be amiss, but Mr. Congden as a student of law understands that the average legal document is no less technical, and he could degrade a lot of professions by presuming upon the ignorance of the populace. "Cruelty to animals," as he expressed it, might then have a broader application. It is more to the point to have the Geological Survey and all Provincial Departments of Mines adequately organized, supported in a manner conforming to the ambitions of the country, and to have it officially admitted that Mineral Industries are pre-requisite to greater prosperity.

Dealing with the Immigration impasse, Mr. Congden was in happier vein. Under prevailing embargoes, "Lao Tze or Confucius could not come to Canada; Socrates would have been barred as a vagrant, and St. Paul would have talked too much for the liking of our authorities. Besides, he was hunch-backed. Judas Iscariot, on the other hand, would have been welcomed for his 30 pieces of silver."

While exaggeration is permissible in the circumstances, ridicule is more effective and Mr. Congden availed of it to bring about modifications in the regulations. Systematic prospecting, the sectioning of Quebec to that end, strengthening and simplification of the work of the Geological Survey, are laudable objectives. What is the prospector going to get if essential skilled and unskilled labor is not obtainable for even producing properties? Recruiting of labor has precedence at this writing.

Death of Major General Sir John Carson

The death of Major General Sir John Carson,—Ex-President of the Crown Reserve Company, prominently identified of late with the Asbestos Industry, a life-long soldier, civic and on active service—was expected. A stroke had made it inevitable. What he did speaks for itself. His Peace and War work gave him a place on the Roll of Honor — and what better could he leave as a heritage! Moreover, he gave a son to the Allied cause, and sacrificed most of his own fortune to it. Decorated by the Empire, as well as by what was an Empire—Russia—he died among his friends and left a record of deeds that are still influencing North Country developments.

The Dome Quickstep

To quote a Dome official: "We can't find anything but high grade." Both walls are asserting the merits of contact country, and the pace can be maintained, for some time at any rate. Enough is assured to sustain handsome dividends and redeem capital on the double-quick, and that is a very different story from what was told in the earlier operating years. While the going is so good, the Dome Treasury will be all the stronger, and it is to be emphasized that there is a substantial tonnage of ore broken in the stopes—more than ever there was. In the nine months to October, production amounted to $3,086,275—practically double what it was in 1921. At that rate the 1922 production will total about $4,400,000 gross or cent per cent on issued capital. With $13,000,000 from Hollinger, $4,400,000 from Dome and McIntyre gaining, the Porcupine trio of producers may come near to the $20,000,00 mark, thus exceeding any State in the United States.

Partial Coal Solution

Headed by Deputy Minister of Mines Camsell, a Commisson of Departmental Scientists at Ottawa is reported by the Canadian Press Association to be about to seek a solution of Canada's Coal Problem. The central idea is to promote the use of domestic fuel. Not a bad idea by the way, if we go about it in the right way. It almost seemed as though Canadian Coal was becoming anathema — unless the railways made it possible to bring along better grade western fuels. The latest Commission is to see whether the Maritime Provinces product cannot be given larger domestic markets by means of by-product coke ovens. Again the daily press seems to have forgotten that there are already extensive by-product ovens, installed at considerable expense. Had those ovens been availed of, or were they located at a more central point, coke could be had and the market for by-products during the recent coal strike in the States would have been very profitable.

Professional "High-Graders"

Rascality on a large scale — not mere contumacy — has been back of the extensive "high-grading" for which several thieves are under arrest. Probably those who are in the toils are the mere dupes of those who procured the ill-gotten gold. It does not matter so much who were the principals and who were the crooked "simps", so long as there is a complete exposé, and adequate punishment is meted out to the organized gang. By making an example now of the culprits, the danger of recurrences of the thievery may be obviated. The men behind the thieves should have the limit of the Law. That is the only effective way in which what is an evil in every gold field can be restricted. Whoever are the "higher-ups", they should be brought to book. Elsewhere punishment has been imposed that has met the situation, so why not in Northern Ontario?

Lawson's Emblematic Elephants

"To [illegible] a dozen ivory elephants cherished by Tom Lawson had to go under the hammer. The ex plunger patterned most of his "biggest stock coups on scales suggested by the contemplation of the beast's size", it is explained. The collection brought $57.50, elephants being a buyer's market. Now Lawson will be without inspiration. He has one consolation, however, his pachyderms were negotiable, even as a Job Lot. Therefore, they differ from collections of share certificates and prospectuses, which merely offend olefactory nerves. Lawson's following ought to have purchased the elephants and donated them to a Curb Exchange, where braying bipeds frequent the arenas. "The beast's size" appealed to Lawson — why not others.

Washington's Gold Hoard

On October 1 the Federal Reserve Banking System held $3,060,501,181, of the $3,874,178,711 in gold in the United States. In other words, the Federal Reserve is 79 per cent of the American gold holding, and the grand total in the States is nearly half the world's "visible supply." The Nest Egg is large enough, but needs fertilizing.

Pinnacle Lake Prospects

Crown Reserve officials are favorably impressed with the results obtained in the shaft and from what little additional work has been done. The shaft is down 300 feet. In it narrow new veins, distinct from what was outcropping and drilled, have been noted. Values are alleged to be attractive, insofar as they go. Structural features in due course will be elucidated, and if widths and values are maintained it may be the Crown Reserve's history will commence another chapter. The larger section tapped by three holes was not very enthusing. It is the presence of the smaller things, and the values, that make the locality interesting. Even the Associated Gold Fields of Larder Lake is alleged to have milling grade calling for further demonstration. It will require a few million tons to measure up to their be millioned capital.

Asbestos Corporation Expansion

It bespeaks confidence in the outlook to have the Asbestos Corporation of Canada announce its intention to expend approximately $500,000 upon milling additions that, needless to say, will be modern and efficient, costs and economies being a factor of increasing moment. The intimation is that contracts will be let and construction started as soon as the Quebec Government decide as to the mooted export tax. No new financing is contemplated, for the corporation has cash resources of over $2,500,000.

News of Mining

Great Britain

Speaking at the [illegible] meeting of the Ebbow Vale Steel, Iron & Coal Company, Limited, Sir Frederick Mills, Bt., stated that the Company had been treated very shabbily by the Minister of Munitions. During the war the Ministry ordered the company to erect 20 blast furnaces in certain parts of Great Britain and made no promise for their completion until after peace had been declared. Sir Frederick declared that five furnaces completed would have served the Ministry. The company now has the furnaces on its hands and must [illegible] cost of a bad bargain.

United States

According to [illegible] press correspondence, Henry Ford's activities in coal [illegible] plants as a protest against coal profiteering will not stand close examination. Mr. Ford, after he had expressed the opinion that prices set by the Government were fair, was offered the entire output [illegible] by Michael T. Roach, President of the Union Fuel Company, at government prices. The offer was evaded by Mr. Ford, who proposed to [illegible] instead of closing down. In an interchange of [illegible] it appeared that Mr. Ford claimed that [illegible] he would get coal f.o.b. mine at $2 per ton. This statement was strongly questioned by [illegible].

In [illegible] the monthly average of coal used in the [illegible] coke ovens has fallen from 1,351,000 tons to about 800,000 tons.

At [illegible] the grand jury in the Herrin (Southern Illinois) massacre case has indicted 59 persons on the charge of murder and conspiracy. The United Mine Workers are making violent efforts to block the progress of the investigations. Evidence is now being given freely and in ghastly detail. One taxicab driver is charged with cutting the throats of the wounded. The union is levying contributions for the defence of the accused.

A striking instance of industrial conservation is afforded by the action of the Anaconda Copper Mining Company in purchasing recently a Florida phosphate rock deposit. The recovery of the company's waste sulphur gases will enable it now to enter the field as a producer of fertilizers. The price paid for the phosphate property is said to have been $1,000,000.

In a summary of development of the shale oil industry in the United States, published in the Journal of Industrial and Engineering Chemistry, Professor Ralph N. McKee stated that the known deposits of oil shale in the States and in the Maritime Provinces must be developed and utilized as they are the only source of petroleum after exhaustion of the probable supply from wells. He estimates that to meet the increasing demand for petroleum, even making no allowance for the expected decrease in the production from oil wells, will require the construction each year of 75 shale oil plants each with a capacity of 2,000 tons of shale per day and each entailing the investment of nearly one million dollars.

The price of lead has been advanced from 6 cents per pound to 6.10 cents per pound by the American Smelting and Refining Company.

The pre-natal effect of high tariff legislation is seen in the heavy decrease in the importation of gold in the United States. Gold imports during August amounted to $19,000,000, as compared with $8,000,000 in August 1921, and with $13,000,000 during July of this year. Gold exports reached the figure of $5,000,000. Imports of silver for August aggregated $5,000,000; exports totalled $1,000,000.

The National Lead Company, which [illegible] Simon Patino, the Bolivian tin [illegible] investors, owns the Williams Harvey Company, Limited, of England, and the Williams Harvey Corporation of New York, has acquired a large [illegible] in the

Compania Estanferam, Chile, the largest producer of tin in the world. The purchase was facilitated by the decline of the Chilian peso to under ten cents and the consequent fall of the Compania Estaniferam shares on the Valparaiso Exchange. The Williams Harvey-National Lead people have thus been able to secure long-term contracts for about three-quarters of all the tin ores produced in South America. The Williams Harvey smelters in England are the largest now in operation. It is stated that the consideration paid was $1,500,000.

Word has been received in New York that the British Controlled Oilfields has struck oil on its Buchivacoa concession in Venezuela. It is stated that the oil was encountered at a depth of 630 feet. The Standard Oil Company, through one of its subsideries, arranged recently to take over the development of half of the British company's holdings. The Imperial Oil Company Limited, of Canada, is the subsidiary in question.

The pipe line of the Illinois Pipe Line Company is being extended into Montana oil fields and large storage tanks are being erected to provide for handling the increased flow in the Kevin-Sunburst area, Toole County. Arrangements have been concluded whereby most of the production will be taken by the Imperial Oil Company of Canada.

Europe

Figures made public by the German Federal Department of statistics show that the wages of coal and lignite miners have gone up somewhere between 2,000 and 3,000 per cent since 1913. Surface workers are now paid an average of 109.19 marks per shift, an increase of 2,777 per cent over 1913; hewers and trammers get 131.54 marks, increase, 2,185 per cent; other underground workers average 106.86 marks, an increase of 2,538 per cent.

Confirmation has been received of the report that the Standard Oil Company has obtained concessions from the Government of Czecho-Slovakia, permitting it to exploit the unexplored oil territories of that country. The Standard's subsidairy in Czecho-Slovakia is the Franco-American Standard Oil Company.

Government attempts to nationalize the Rumanian petroleum industry are blamed for the present decline in production. Present outputs it is stated, amount to only one-third of the pre-war production, and the greater part is absorbed by the Government. Railways are in bad condition and much oil is going to waste because of the shortage of tank cars.

For the first five months of the year the production of crude oil in Poland was 281,321 tons the largest output for any one month being recorded in May when it reached 61,296 tons. The bringing in in July of the Ratoczyn No. 1 well at Boryslaw, with a daily flow of 150 tons, was the outstanding event of the summer's development.

The French Minister of Public Works, according to the Paris publication "Information", will in the future require holders of new minging concessions to form a Syndicate for the regulation and promotion of the sale of ores, etc. It is suggested by the writer of the article that groups or sub-syndicates be formed for each class of ores. Another suggestion is that trading companies now engaged in importing and exporting be entrusted with the marketing of the various ores, thus minimizing the evil effects of competition between individual producers.

Australia

A gold mine that is noteworthy for its longevity is the No. 4 North Phoenix, Gympie, Queensland. It has been working for 41 years. Since the year 1882 Mr. James Brown, the present manager, has been in charge. This summer a lot of 120 tons of ore yielded 3,358 ounces of gold.

At the Central mine, Broken Hill, New South Wales, the main vein recently showed a 12-foot face of galena averaging 68 per cent lead and 20 ounces of silver to the ton.

A bucket dredge is being erected in the Macquarie River near Wellington, New South Wales, with a capacity of 600 tons per hour. Each bucket has a capacity of 13½ cubic feet. The average gravel value is 1s. 4d. per cubic yard.

At the Central mine, Broken Hill, New South Wales the addition of 500 tons weekly from an 18-year old slimes dump is made to the ore being milled. The recovery is satisfactory and the results suffice to keep the mine on a paying basis. The dump contains about 1,500,000 tons. At the South mine, in the same locality, an old dump of about 200,000 tons is being re-treated at the rate of 2,500 tons per week. Here, also, the company depends upon the addition for its net profits.

In the Kalgoorlie district of West Australia, the Crow's Nest gold mine, near Yalgoo, milled 1,200 tons of ore during July for a yield of 900 ounces.

Africa

A British consular report from Lourenco Marques, Portuguese East Africa, states that there has recently been much prospecting carried on in that country. From the Zambesi region the discovery of oil is reported. Tin also, according to information received, has been found. A coal seam near Tete is at present being examined.

F. S. Pearson Engineering Corporation, Fisk Bld., Broadway and 57th. Street, New York City, have re-established their Department for Industrial Management and Technical Auditing of Industries and Public Utilities. This Department will be carried on, together with their usual work of financing, developing, design and construction of Engineering Projects and Industrial Plants.

The Canadian Link Belt Company Limited, Toronto, have just issued a new 832 page general catalogue which, they advise, is the most complete and costly they have ever issued. This catalogue includes their new line of Helicoid Screw Conveyors, Machine Moulded Gears, etc., and will undoubtedly prove of great value to those interested in elevating, conveying, power transmission and labour saving machinery in all its modern forms. The catalogue includes a complete line of the H. W. Caldwell and Sons Company's Plant of the Link-Belt Company. It is available on application to their Toronto Office, Wellington and Peter Streets or Montreal Office, 10 Gauvin Lane, to anyone who will state his connection with the mining industry.

By the Treaty of Versailles, the island of Spitzbergen was given to Norway, its ancient owner. Since that time Norwegians have been active in developing the coal deposits of the island. It appears now that the quality of the coal is not so high as was expected, and the Norwegian investors are in serious finacial difficulties.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

ONTARIO

NORTHERN ONTARIO

(Special Correspondence)

Origin of The Fire

It now appears that the fire that devasted such a large area in Northern Ontario was not a regular forest fire, in the ordinary sense. The country that was burned over was, for the most part, clear of forest and comparatively well settled, and the fire swepth through small second-growth green bush and settlers' clearings. A large number of small fires wert joined into three or four larges ones by the sudden and heavy wind that sprang up.

Dr. C. D. Howe, dean of the Faculty of Forestry of the University of Toronto, states that forest fire prevention is a question of public morals, and that there will never be adequate fire protection in Northern Ontario or anywhere else until the people demand it. A complete survey will be made of the burned area by the Government and steps will, no doubt, be taken to avoid a recurrence. It is, unfortunately, the habit of the Government to withdraw the Forest Rangers on the 15th of September, irrespective of conditions. There is no question that, in view of the extremely dry season, the rangers should not have been withdrawn and further, that no settlers should have been allowed to burn slash under the conditions that prevailed and in any case only under the supervision of the Rangers. If more stringent measures are taken regarding the burning of slash, our losses from bush and forest fires will be greatly lessened.

Relief Measures

Latest reports show that over 40 people are dead as the result of the fire, while it is estimated that over 8000 people are homeless and that property damage will run in the neighborhood of $8 000 000. Effective relief measures are, however being taken, and at present time everybody is under shelter of some sort or other, and is being supplied with food, blankets, mattresses and stoves. In some of the farming districts the losses are particularly severe, and in one township, 64 settlers are homeless out of a total of approximately 78. Under these circumstances relief will have to be given for a long time, and in many cases fodder also will have to be provided for the stock. There are not enough houses in the district to take care of the population, so the relief committee is purchasing lumber in large quantities with the intention of providing the lumber for shacks 16 feet by 20 feet for those who will build and occupy them.

Within a few days after the fire Haileybury and New Liskeard were provided with light and power. The Northern Ontario Light and Power Company are making strenuous efforts to repair the damage done to their transmission lines and sufficient power was obtained at Charlton to provide for pumping the Kirkland Lake mines and lighting for the town. It will, however, be a week or more before the damage is repaired sufficiently to enable the Kirkland mines to resume operations. The two mines in South Lorrain are again working, power having been provided for them on the 7th. During the last few days there has been enough rainfall to provide sufficient water in the Montreal River to generate sufficient power to carry the load in Cobalt. Companies were notified on the 13th, that there was sufficient power for their requirements and operations again commenced.

Keeley Output

Recent developments at the Keeley continue to be favorable and the September output amounted to 83,000 ounces, which is the highest in the history of the company. It is anticipated that the company will be able to maintain an output of approximately 80,000 ounces per month.

Mining Recorder now in Cobalt

The Mining Recorder's office has been established in the Town Hall of Cobalt. Some fear is felt regarding the safety of the Mining Recorder's records for the Temiskaming Division, as it is understood that some damage was done to the vault, which fell through to the basement. It is also estimated that approximately fifty mining companies in this Division lost all or part their records, which were in various offices throughout the destroyed portion of the town of Haileybury.

Shipments from Cobalt continue to be large and the shipments from this camp for the month of September were the largest this year, the total being 1,593,000 pounds. Most of this, however, consisted of residues, of which the Nipissing shipped 10 cars, containing 719,000 pounds. Of these, two cars were consigned to a pottery firm in Berlin, Germany. The Mining Corporation also shipped seven cars, containing 588,000 pounds of residues. The O'Brien shipped two cars of ore, and the Coniagas and Dominion Reduction each shipped a car of concentrate.

Castle

Favorable reports continue to come from the Castle property in Gowganda, and it is understood that the annual report, which will be issued shortly, will show ore reserves in the neighborhood of 600,000 ounces.

Lorrain Consolidated

A deal is apparently being negotiated for the Lorrain Consolidated, as a large block of stock recently changed hands. The property adjoins the Keeley and the Frontier, and in view of the favorable results being obtained on both these properties, either the Keeley or the Mining Corporation is the likely purchaser.

A Deal in Dumps

The Dominion Reduction has entered into an arrangement with the Crown Reserve for the treatment of the latter company's surface dumps.

Lake Shore Shaft

The annual report of the Kerr Lake for the year ending August 31st last, shows total receipts of $1 501 181, and net profits of $413,870, a decrease of $65,000 compared with the previous year. Dividends amounting to $300,000 were paid, the and Profit and Loss surplus is shown as $1,228,000. The revenue of the company has come from the operations of the Vipond

BRITISH COLUMBIA

Dr Hanson Returns From Portland Canal

Dr. George Hanson, of the Canadian Geological Survey has returned after spending the summer in geological research in the north of British Columbia. He says that the camp at the Premier Mine, Salmon River, has been built up to such an extent in two years that one scarcely recognized it. He spent a considerable part of his time in the country adjacent to the town of Terrace on the Grand Trunk Pacific Railway. In this district four prospectors were developing a high-grade property and hoped to be able to ship a carload of ore to the smelter, after transporting it 40 miles by wagon road.

Large Nugget From Cariboo

D. J. Ashley, of the Cedar Creek Mining Co., is exhibiting in Vancouver one of the largest nuggets that has yet come out of the Cariboo. It is about 1½ inch in length and weighs 3 ounces.

Kleenza Creek Area Promising

The Peerless, Montana and Wells groups of mineral claims, situated at the head of Kleenza Creek, Northern B. C., are looking very well on development. The veins have been proved at depth and there appears to be a considerable amount of high-grade ore as well as a large body of lower grade. The principal values are in copper.

Granby Achievements and Plans

It has been announced that all the 2500 employees of the Granby Consolidated Mining & Smelting Co. received an increase in wages on October 1st, amounting to about 50 cents per day. This Company, it is stated, expects to produce 30,000,000 lbs of copper this year. During the first part of the year the production amounted to some 13,000,000 lbs, but since the end of June operations have been speeded up. Plans have been completed for a concentrator, but the time has not yet arrived for its installation. Eventually, however, Granby will become a milling proposition. The hydro electric installation is being hurried to completion and it is hoped that it will be ready by the end of the year. This will mean a reduction in cost of from ½ to 2 3 of a cent per lb.

Further reports have been received of new activites of the Company in the north. It is stated that a bond has been taken on the Outsider Group, consisting of eight claims, situated at Maple Bay on the Portland Canal, about 35 miles from the town of Stewart. This property was located by William Noble and G. M. Collinson in 1903. It was sold by them to the Brown-Alaska Co. in 1905. The latter shipped 14,500 tons of ore to the Hadley Smelter, Prince of Wales Island, Alaska. The returns on these shipments gave 3% copper and averaged about $1.00 in gold and silver to a ton. During this period a Riblet tram 1 mile in length was built to the beach, where a 1,000 ton bin was constructed. The plant was closed in 1907. New interests acquired it in 1908. There followed a long period of inactivity until 1917, when something like $35,000 was spent on development work, the results of which have been encouraging. The Granby Co. are said to have given the contract for further tunnelling and general exploration. Over 200,000 tons of ore have been blocked out and shipments to the Anyox smelter will commence next season.

Mineral Exhibit in London

Samples of the minerals of British Columbia are being collected under instructions issued by the Hon. Wm. Sloan, Minister of Mines, for the purpose of augmenting and bringing completely up to date the exibit at British Columbia House, London, England.

In the past few years there have been many new mining properties opened up in this Province. Some of these are in the Kootenay, others in the Boundary zone, and not a few in the North. Among the latter are those of the Portland Canal district. It is the intention that all these properties shall be represented in the display in the Old Country. The work of getting first class examples of the ores of such properties, and of procuring specimens of what new minerals have been brought to light, has been under way for several months. When the shipment finally goes forward it will be in such shape that visitors to British Columbia House will be able to ascertain at a glance the character of the outstanding minerals of British Columbia, as well as obtaining an idea of the appearance of the ores of the better known mines, such as the Premier and the Sullivan.

Already there are a number of large cases of samples, carefully selected and indexed, in the offices of the Provincial Mineralogist awaiting shipment to England. These are for the Empire Exhibition of 1923. They are thoroughly representative and it may be assured will constitute an exhibit that will be a credit to this Province.

Copper Deposits on Vancouver Island

The Gabbro Mines Ltd., whose properties are situated on Jourdan River, west coast of Vancouver Island, have been doing much prospecting development during the past two years. This year two new zones, known as the "Stewart" and the "Pat", on the Vulcan No. 3 Claim, have been opened up. These are important as establishing the continuity of the ore body on the east side of the river. The "Corfield" zone has been opened on the Black Hornet Claim, west side of the river.

Adjoining these holdings is the mine of the Sunloch Mining Co. There has been little development recently on this property. The management is marking time, pending the installation of the promised concentrating mill. An announcement was made by the Consolidated Mining Smelting and Power Co. two or three years ago that an appropriation of approximately $125,000 had been made for this work. The project has got no further, however, no doubt for the reason that the price of copper still is low.

Test of Dome Mountain Ore

Thos. J. Jefferson, mine operator interested in northern British Columbia holdings, states that the development of his property on Dome Mountain this summer has been very satisfactory. A trail shipment of ore containing high gold values has been sent to the smelter for treatment. The results are to be taken as a guide for plans in the future. Next year he proposes diamond drilling, the drill to be taken to the town of Telkwa during the winter to be ready for an early start in the spring.

Dolly Varden Owners Issue Shares

The Northern Mining Properties Ltd. are issuing shares to the creditors of the defunct Taylor Mining Co. Ltd., of Vancouver B. C., which formerly operated the Dolly Varden Mine at Alice Arm.

Big Block of Galena Found

It is reported that miners working on the claims of J. C. Pitts, a merchant of Invermere B. C., have uncovered a solid block of galena measuring in the rough

Silver property in Utah, and a gold dredging property in New Zealand.

Lake Shore Shaft

The Lake Shore has completed the enlargement of its shaft to a depth of 400 feet, and now has a three-compartment shaft to the 600-foot level. When power is again available, sinking to the 800 foot level will be started, preparatory to the enlarging of the mill.

Teck-Hughes

It is understood that directors of the Teck-Hughes are considering a proposal for paying off the bonded indebtedness in annual installments. If this done there is nothing to prevent the company going on a dividend basis almost immediately.

Activity in Skead Township

There is considerable activity in Skead Township, and it is understood that A. D. Miles, representing English interests who recently took an option on the Skead Gold Mines, has also taken over the Telluride claims. The Flannigan claims have been optioned to A. J. Young and associates, while the Mines Finance Corporation has taken an option on the Malen group. Diamond drills are now at work on the property of the Skead Gold Mines.

[illegible] to Re-Organize

At a meeting in Toronto of the shareholders of the West Dome and Dome Lake it was decided to liquidate these companies in order to facilitate the distribution of the stock of the Consolidated West Dome Lake. The latter company was formed to take over the two companies, and old shareholders will receive one share of the new stock for two shares of the old.

Paymaster Report

Another spectacular discovery has been reported on the surface of the Paymaster property. A few weeks ago this company tried to create excitement by reporting a find of \$15,000 ore on the 300-foot level. It is not difficult to obtain this sort of an assay from almost any of the Porcupine properties, and the publicity given to this statement, [illegible] from company officials, leads one to [illegible] that the company has an eye to stock distribution.

[illegible] Properties to be Re-Opened

It is [illegible] that arrangements are being made to resume [illegible] at the Fairbairn, Murray, Mogridge and Baldy [illegible], which lie a few miles north of Swastika. All these properties have shafts down to a depth of [illegible] feet.

Pamour Lake

The [illegible] is stated to be encountering very encouraging [illegible] the Pamour Lake property new vein which was found at a depth of 275 feet. The vein has a [illegible] and values are reported to be very [illegible].

Porcupine Gold Production

Northern Ontario gold mines have produced over \$2,000,000 during the month of September, which establishes a record for Ontario mining. While the October output will probably not be as high as this on account of the [illegible] at Kirkland Lake due to the shortage of power, it is expected that this record will be beaten during the [illegible] months of the year.

The Dome Mines established a new high record with an output of \$[illegible], being \$13.51 a ton from 31,304 tons [illegible]. The mill is now treating over 1100 tons per day. [illegible] developments continue to be satisfactory. The Hollinger also established a new record, and is now treating 4500 tons per day. It is anticipated that with the new crushing plant that is being installed, production will soon be 5000 tons per day.

McIntyre is also breaking into new ground and establishing new records. The recent discovery on the 1875-foot level has given the mine a new lease of life. No. 7 vein, which is a continuation of the 84 vein on the Hollinger, has been developed for a length of 800 feet, giving an average of approximately \$20.00 per ton. To the west there remains 400 feet of undeveloped ground to the Hollinger boundary, in which the ore has been indicated by diamond drilling, and a further 400 feet to the east has also been indicated by the drills. This would given a length of 1600 feet on the McIntyre ground. This vein has been the most important producer yet found on the Hollinger, producing to date \$15,000,000, with an estimated reserve of over \$6,000,000 above the 800-foot level. Practically no work has been done on it in Hollinger ground below that depth.

NORTHWESTERN ONTARIO

Prospector's Licenses at Kenora

One hundred and seventy mining licenses have been issued here since the rush to Red Lake started a little more than a month ago. Some fine samples of gold quartz have been brought by prospectors, who state they took them from veins not far from Red Lake, although neither near the silver find nor in a similar rock formation.

Mikado being Unwatered

The Mikado is now unwatered to below the sixth level. Twelve men are at work, and thirty more are to be put on immediately. Those interested in reopening the property profess to have ample financial resources to carry on until the spring, when it is expected results will have warranted more serious operations. Col. Machin is showing some gold in quartz, taken from the surface at a point about 400 feet from No. 2 shaft, that are of the same sensational nature as used to come from the Mikado formerly when the mine was active. — C. A. B.

NOVA SCOTIA

Agreement May Bring Prosperity to All

Now that the wages agreement is signed to cover a period of eighteen months, we can expect the co-operation of miners and management in an attempt to bring back prosperity to the coal mining communities of Nova Scotia. President Dan Livingstone of the United Mines Workers Local, has expressed high hopes that the present agreement will be beneficial to all concerned. The high level of wages makes the common benefit somewhat doubtful as far as the Company is concerned.

A Busy Winter Promised

Shipment of coal continues to be brisk and will probably remain so until the season for navigation closes. Last week the prospect for continued activities during the winter were not bright. The recent order for [illegible] tons of rails has altered the case, and it appears now that not only will the steel plant be busy during the whole winter, but as a consequence the mines also will be enabled to work more nearly to capacity.

19 by 19 by 20 inches. It is estimated to weigh approximately one and a half tons, being practically solid sulphide. Arrangements are being made to have it exhibited as a specimen of British Columbia mineral.

Dr. Dolmage Announces Silver-Lead Find

Dr Victor Dolmage, of the Canadian Geological Survey, recently lectured to the Victoria Prospectors' Association on the Vancouver Island minerals and mineral formations. The speaker referred to the Old Sport and Tidewater properties as being good examples of the mineralization of the Island and announced the discovery at Quatse Lake, near Coal Harbour, Quatsino Sound, of a body of galena carrying good silver values. It occurs in limestone on a contact with a colored granite that may possibly be of Tertiary age. Dr. Dolmage also described some peculiar dykes of volcanic glass that he examined in the Douglas Channel area last year as well as of beds of volcanic tuff that have been deposited on glaciated surfaces of the Coast Range granite.

B. C. Coal Reserves

It is estimated that the coal resources of British Columbia total 73, 874,942,000 tons. This includes an actual reserve covering 439 square miles and containing 23,831,242,000 metric tons, as well as a probable reserve of approximately 6,195 square miles containing 50,043,700,000 metric tons. These figures were compiled recently with a view to arriving at some conception of the value of the natural resources of the Province. They are illuminating as an indication of the possibilities of coal mine development in this section of the Canadian West.

Good Production at Crow's Nest

Figures showing the production of the Crow's Nest Pass Coal Co., Coal Creek, last month are not yet available, but it is expected that they will be about the average, notwithstanding the prolonged period of inactivity owing to the recently settled strike. The mines have been kept in first-class condition. There was nothing to prevent an almost immediate resumption of production on a normal scale, except an unexpected shortage of railway cars.

The Normandale is a new colliery opened up near Nicolas, B. C., which made its first shipment last August. The coal is a high-grade bituminous. It is necessary to truck the product for two miles to the Kettle Valley Ry. Mr. Ewart is in charge of operations. Vancouver City capital is invested in the enterprise.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclosed ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

CHEMIST, experienced in blast furnace and steel plant work, ores etc., desires position. References. Address Box 521, Canadian Mining Journal, Gardenvale, Que.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

EDITORIAL

The maritime and mineral resources of the Acadian provinces constitute them the Great Britain of Eastern America; and though merely agricultural capabilities may give some inland and more southern regions a temporary advantage, Acadia will in the end assert its natural pre-eminence.—Sir William Dawson—1878.

CANADA'S COAL — A FORECAST

Mr F. W. Gray, formerly editor of the *"Candian Mining Journal"* and now once more on the staff of the British Empire Steel Corporation has submitted for the President's Prize Competition of the Canadian Institute of Mining and Metallurgy a paper on the *Development of the Coal Industry in Canada*. This has been published in the October issue of the Institute's Bulletin. We wish to draw attention to it as one of the clearest and most authoritative estimates of our national fuel supply that has yet been published. It is from the pen of one of the few Canadians who have studied our fuel problem in a comprehensive and disinterested way. Mr Gray has made the study of coal his life's work and has applied to the task without stint both the energy and the discretionary power of which he is capable in eminent degree.

After pointing out that to secure our coal supply mainly from abroad as a mere matter of convenience and expediency is a pernicious principle and contrary to the true interests of our country, Mr Gray reviews our present sources of fuel and shows how Canadian sources can be used to greater advantage. For domestic purposes we use principally Pennsylvania anthracite, an ideal fuel for such use. This is becoming more and more a luxury. It is probable that dense coke made from bituminous slack coal in by product ovens will replace anthracite for domestic purposes in Canada within a measurable period of years.

The problem of using Canadian bituminous coal is primarily one of distribution. There is plenty of coal in both east and west and we must discover ways and means of making it available as far into the centre of the Dominion as possible. Nova Scotia with coal reserves that are comparatively small, can produce economically ten million tons per annum which is about twice its present production. It is probable that this coal can be shipped with economy as far west as a line joining Ottawa and Brockville. West of that it will be expedient to use imported coal, until it becomes feasible to use western Canadian coal at, say, Fort Frances. Throughout the west our fuel supply is assured for all time, in any quantity that may be required.

The feature that will mark the development of coal mining in Nova Scotia, where there is already a unified control and a consistent policy of production, is economy of production by means of all possible means such as labour saving devices, efficient underground transportation, a more complete saving of coal, and the preparation of cleaner coal for market. In the west the production of coal is still in a somewhat chaotic condition, due to its virtual omni-presence and the consequent irrational competition. A commencement has been made already in the Western Canada Coal Operators' Association, to coordinate the aims of the various operators, which are at bottom identical, and to ensure a maximum of efficiency in the total production.

Looking to the future, Mr. Gray makes some shrewd estimates as to what Canada's requirements for fuel will be. Basing his estimates of population for the next thirty years on the growth of the United States population a century ago, and making due allowance for the effect of our more rigorous climate on settlement, he finds that by 1950 Canada will have a population of 8,000,000 from Manitoba westward, which will consume 12,500,000 tons of coal. Most of this coal will come from Alberta mines, and its increased quantity will be dependent almost entirely upon increase in population. The Vancouver Island mines will have a comparatively small production, as indicated above. Of the 52 million tons of coal estimated to be mined thirty years from now, 38 million or 73 per cent. will be mined in Alberta, Saskatchewan and eastern British Columbia.

The central part of Ontario will require an increasing amount of bituminous coal from the United States, where the superabundant supply will be available except in such cases as that recently experienced. This will not be balanced by any corresponding export of Canadian coal. "Generally speaking it does not seem probable that Canada will become a dominating factor in the export coal trade of the world, although the country can play a respectable role in this way for an indefinite period ahead. Canada's chief hope of benefiting from coal deposits within her borders is by a combination of domestic industries and agriculture, and the development of a

"wholesome fear among our people of too great a de"pendency on the United States coal fields."

In conclusion, the alternatives to coal as fuel are mentioned—electricity, peat and oil from shale. They may be important locally but do not affect the general issue materially.

We have noted Mr. Gray's paper thus at some length not only because of its outstanding intrinsic merit, but because it presents a foundation upon which we propose to build. Canada's fuel problem is so pressing and so serious a matter to one and all that the "*Canadian Mining Journal*" intends to keep it constantly before its readers in such a way as to induce a more extended use of domestic fuels. We all need education along this line. If we can expand Mr. Gray's resumé into a series of expositions, equally authorative, elucidating each of his various principal conclusions, we shall have a solid body of information on which to act. This the *Journal* intends to do during the coming months.

PROSPECTING VERSUS THE "RUSH"

The favourite season for "rushes" to new mineral finds is upon us, yet there is a surprising scarcity of those wild scrambles. It cannot be for lack of men to follow a rush, for the woods have been full of prospectors and would-be prospectors during the season just closing. Nor can it be for lack of an excuse for a rush, for some of the most famous of these have been based upon the flimsiest of pretexts, or even upon bare-faced scheming with no find whatever in the back-ground.

It seems more likely that our prospectors, having been led astray so often by a false scent left by the feet of an incompetent or an unscrupulous fellow-prospector, have now adopted generally the habit of marking out their own courses and sticking to them. In other words, prospectors today are more inclined that formerly to work out their own salvation by means of a consistent and well-directed search, rather than to depend upon following up, helter-skelter, the tracks of a successful comrade in the hope of sharing in his lucky strike. True, so often as there is a strike there will be a congregation of prospectors and an intensive search in the vicinity that will aid not only the original discoverer but the progress of the area as a whole. A certain amount of "rushing" is legitimate and useful. It is the "rush" in excess that aids no legitimate object and wastes a deal of money and of human effort.

A consistent plan of work is available to a much larger fraction of our prospectors now than formerly. Prospecting has become more of a recognized trade or profession than it was twenty years ago. It is no longer merely the resort of the odd character, impelled by unknown forces to wander through forest or desert, cut off from his kind and regarded almost as a separate species. The prospector of to-day informs himself, as well as may be, about the minerals for which he is searching and the known facts of their occurrence. He avails himself of every aid the geologist has to offer, and is capable of applying logically to the work in hand the data obtained from working deposits and from field mapping. He is no longer hunting for a needle in a haystack; he is following a thread through a maze of thickets and rocks—a thread broken, no doubt, at intervals, but sure to lead him to his goal in the end if he persists and uses his head.

Prospecting is at present in a period of transition. The "rush" belongs to the old order rather than to the new. It is a picturesque feature of the search for mineral deposits, and it will always remain, albeit in modified form, so long as "strikes" are made. Our mineral industry will benefit materially from the transference of a large part of the energy consumed thus fruitlessly to a search directed upon more modern and saner lines.

FIRE CAUSED BY NEGLECT

There seems to have developed quite an air of mystery about the origin of the devastating fire in Temiskaming district three weeks ago. Actually there is no mystery whatever about it. It is a plain case of neglect on the part of persons who should have known better than to run the risk of conflagration. It is of the utmost importance to our northern mining communities that recurrences of such fires be prevented. Hence, at the risk of repetition, we shall state the case once more, and even more clearly.

Four days before there sprang up the gale that fanned the flames to the danger point, a mining man, well versed in the ways of the woods, travelled along the Temiskaming and Northern Ontario Railway from Cochrane to Cobalt. The countryside was wrapped in a pall of smoke. Everywhere settlers were burning slash. A casual inspection showed the woodsman that the fires had burned through to the clay below, and were spreading laterally at will. A hundred miles of dry fuel, continuous almost throughout, had been kindled in a thousand spots. Winds were bound to come. Only an act of God, in the form of rain before the wind, could avert the impending catastrophe. That rain came too late.

This is, briefly, the whole story, so far as it can be learned in the devastated northland. Commissions of investigation there will prove fruitless. It is in Toronto, at the seat of the provincial Government, that investigations must be instituted.

So long as settlers, and others, are allowed to burn slash from their clearings while there is danger of the fire getting beyond control, just so long will forest fires inevitably ensue. It has been demonstrated a thousand times, and it has been accepted as a fact, that it is unsafe to leave the question of safety in this case to individual judgment. That is the basis of the laws and regulations directing the use of fire in forested areas. We maintain admi-

nistrative officials and a corps of fire rangers to enforce these laws and regulations.

In the present instance either the regulations have been inadequate on their enforcement has been lax. In either case our public officials in Toronto need not go beyond the walls of the Parliament Buildings to fix the responsibility for the disaster and to provide, so far as is humanly possible, against further costly mistakes.

BELCHER ISLANDS IRON ORE

Dr. G. A. Young's report on the iron ore of Belcher Islands, summarised in this issue, makes it obvious that Canada's iron ore problem will not be solved by means of an unlimited supply of high grade ore from that part of Hudson Bay. That quarter of Canada is an old stamping ground for Dr. Young, for he was a member of Dr. A. P. Low's expedition of 1902-03 which examined a long stretch of the adjacent coast of Hudson Bay, spending two summers and a winter on that cheerless coast. The results of those seasons' work have never been made public formally; but it has become known informally that iron ore, which was the prime object of the party's exploration, was found to no greater an extent than that on Belcher Islands now under discussion, though vast areas of iron formation similarly were located.

After examining in detail forty miles of outcrop of the iron formation of Belcher Islands and having his samples analysed, Dr. Young's conclusion is that no ore of commercial grade is available. It is possible, though not probable, that high grade ore lies concealed by drift.

Perhaps it is fortunate that the ore available in the far-off islands is of so low a grade as to preclude its use until the ore of many an iron range, much nearer civilization, is subjected to a process of beneficiation. If, for instance, Belcher Islands had ore of the purity of the Minas Geraes region of Brazil and in similarly vast amounts, capital might be induced to attempt its commercial use. Even if the ore were of perfect quality it is not likely that it could be used.

Belcher Islands are 470 miles by water from Moose Factory, Moose Factory is 200 miles from Hearst. From Hearst it is 150 miles by rail to Michipicoten Harbour on Lake Superior. Even the most direct route to a market, would require the building of 200 miles of railway, a special fleet of boats and Lake side handling terminals. The whole cost of this would have to be charged against the ore deposits with the possible exception of a small part of the railway that would pass through agricultural land. Via Cochrane and North Bay to Georgian Bay the capital charge would be somewhat less but the railway haul would be longer. The season of navigation on James Bay and Hudson Bay is short, not four months at most, so that the equipment would be idle for eight months of the year unless stock piling were resorted to to cover that period. Belcher Islands is forested and coal would have to be brought by water and boat. Experience has shown that the Esquimaux are not capable of consistent toil, so labour charges would be inordinately high.

All told, it is just as well that the vague hopes we had formed of Belcher Islands as a source of iron ore for Canadian furnaces should be definitely abandoned. The present authoritative report gives little, if any, encouragement for a revival of these hopes even in the remote future.

CLEAN COAL

Ten years ago there was a growing interest among buyers of coal in its quality. The habit was spreading rapidly of buying coal on the basis of its calorific value, the percentage of ash being the principal controllable factor affecting this. The shortage of fuel throughout the latter part of the war period and the succeeding years of abnormal conditions has tended to set back this advance. Now it is high time that a concerted and consistent effort be made to resume our progress along a road that will lead us to true national, as well as personal, economy. In the central part of Canada particularly, where the coal supply is brought long distances by rail, there is an appalling loss annually through the carriage of fuel that contains not less than ten to twelve per cent. ash, and often as high as twenty per cent.

In at least one case, the initiative has been taken by a coal producer. The Dominion Coal Company, threatened by an impending avalanche of cheap coal from Virginia, has undertaken to improve the quality of its product. This policy is sound and far-sighted, and is certain to redound in the long run to the financial benefit of the Nova Scotian coal mines. From now on quality in coal, as in other things for sale, will have added importance both to buyer and to seller.

To-day we print a resumé by Mr. John Moffatt of the means whereby the management of the Nova Scotian collieries are improving the quality of their coal. We draw attention to it as exemplifying one of the numerous and diverse means whereby Canada's fuel problem can and will be solved.

WHEN WINTER COMES*

I've got an office and I pay the rent,
For weeks I've taken in not one red cent
I've got my card in several magazines,
I've joined two clubs—you may know what that means
Of course a fellow's got to have a front;
He can't go round appearing like a runt
And so I have a tailor bill or two
That show some signs of getting overdue
And at this supercritical conjuncture
Financially I'm nothing but a puncture
For, though affairs may swiftly reach a crisis,
My bank account displays sure signs of phthisis.

ANON

*[Editor's Note:—We take strong exception to the implication that any mining engineer, wise enough to take this infallible means of insurance against unemployment could be in such a bad way.]

Coal of Quality

EFFORTS IN NOVA SCOTIA MINES TO PRODUCE BEST COAL

By JOHN MOFFATT

Due to the insistent demand for coal during the war period quantity rather than quality took first place. This tended to carelessness in picking out the refuse material both in the mine and at the picking belts where coal is finally cleaned and assorted. With a stagnant market, the demand for clean coal has returned and the emphasis is laid on quality. Instructions have been issued to all Nova Scotia miners to clean the coal in the mine and see that it is sent up in good marketable condition. For a time a few of the workmen scouted the order for better coal, but the Company was imperative and before long clean coal was being produced from all the mines. But quality implies size, and so efforts were directed towards increasing the percentage of lump coals. This is not as easy as cleaning the coal. The method of mining, the use of explosives, transportation and handling of coal have much to do with its condition when it reaches the market. Friable coal suffers badly from handling, so the whole matter was reviewed and an enquiry begun having in view a larger output of lump coal.

Improved Method of Undercutting

The method of mining in relation to deep and low undercutting was considered. Undermining by coal-cutting machines gives a certain known amount of slack coal according to the kind of machine used. Machines of the puncher type give less slack than the Radial type in the cutting, and the undercut is not only higher but is so made that when the coal is blasted puncher coal falls well out and breaks into much larger pieces. It is easier to load away and requires less digging out and yields a larger amount of good marketable coal than if cut by a machine of the Radial type.

The undercut of the Radial is very low and when deeply undercut the coal after blasting simply settles down in a mass and has in large measure to be dug out by hand. Miners know that to shatter a large block of coal with one shot requires a large amount of explosive. If the block is not thrown outward or downward some considerable distance, it has little chance of being broken into lumps as required. A narrow undercut necessitates an extra large charge of explosive to meet this condition. Too much explosive in blasting pulverizes the coal and tends to give a large amount of slack. In order to obviate this the radial mining machine has been improved lately, and a new device attached that can be used to break down the front of the undercut and make it higher. This snubbing off will not appreciably increase the amount of small coal, as this work is done when the undercutting has been well advanced. It will not only increase the amount of lump coal but, by allowing a smaller quantity of explosives, coal mined in this way will be less shattered and will stand transportation much better.

More Satisfactory Explosive Being Sought

The quantity of explosive and the kind used have much to do with breaking the coal. When loose black powder was used in Nova Scotia collieries it was no uncommon sight to see a whole shot fall in one lump of twelve or fifteen tons. As the mines grew deeper and more dangerous the use of black powder, which nearly always flames in firing, was prohibited and a safer explosive was introduced. Finally the use of permissible explosives became general and safety in blasting became a larger factor in mining than the quality of coal produced. High explosives are rapid in action and are more suited to the blasting of rock than of coal. This is becoming more and more clearly recognized, and the Dominion Coal Company are seeking an explosive that will do the work with less of a shattering effect.

Experiments are now being made with a powder of slower action. Daily records are kept of the quantity of powder used per ton of coal. If the results show equal strength to that of the powder in use and more coal of larger sizes firm enough to stand handling, some progress will have been made. The tests, to be conclusive, will be carried on for a considerable time and in different collieries. Reports from the mine, from the screens and from the shipping piers will be examined, and if the final result shows an increase in larger sizes of coal, everything else being satisfactory, a gradual change of explosives may take place.

Method of Mining Affects Quality

The placing of a hole has much to do with the quality of the coal. Usually holes are bored along the rib directly over the undercut. The rib coal acts as a lever and much of the shattering force of the explosive is spent in the solid coal. Holes improperly placed, just as holes over-loaded, give a large quantity of the finer sizes. Too many holes tend to much breakage and the fewer the holes used, the larger the coal and the better the quality.

The method of mining is therefore of great importance. If a seam seven or eight feet thick can be undercut on the bottom and brought down without splitting it, a larger amount of lump coal will be obtained; but, if seams of this thickness are worked on the fall and bench system, too many holes are required and too much small coal is made. We know that some mining men do not agree with this opinion, but a long experience in the collieries of Cape Breton and Nova Scotia supports the statement.

Forty years ago all coal in Nova Scotia was mined by hand. The cut in Cape Breton collieries was made on the bottom. A method was adopted by which five-foot undercuts could be made. By keeping one-half of a twenty foot room three feet ahead of the other half and shearing in the center, one shot on each side brought down the whole room, filling it up with coal of the best quality. Records show that when an extra effort was made, the amount of lump coal ran as high as 87 per cent. The average, however, was from 75 to 80 per cent lump. When a call for a superior quality came in, miners were prompt to respond, and coal of the finest quality was sent up. The mining, the shearing, the boring, the blasting and the loading of the coal was all done with that fine art of the hand-pick miner, which, through the introduction of machinery, is fast disappearing from the coal mine. The "will to do and the hand to dare" was there and great slabs of coal, too large sometimes to pass over the screens,

found their way out of the mine and had to be broken on the surface. Miners found great delight and much satisfaction in producing the kind of coal called for, and they chuckled as they rolled great lumps of coal, too heavy to lift, up on props or planks into the pit boxes—"for their's was the joy of work well done, the greatest of all joy under the sun."

There were collieries where coal was riddled into the pit car and the slack left in the mine and yet the tonnage rate was less than half of what is paid today. In winter it was 32c per ton. This was laborious work and most unfair to the miner, who received nothing for his extra work.

After riddling underground in order to place large coal on the market was abolished, screens of a large mesh were erected on the bankhead of one colliery and miners were paid according to the weight of coal passing over them. This system was most unpopular. The Company styled the new screen the "bully fair play" but the humor of it all struck the workmen, who gave it the opprobrious epithet of "bully foul play" under which name it died at the hands of the local government.

Specialized Mining

The first mining machines introduced were of the puncher type and undercut on the bottom. The system of mining remained the same as when the hand picks were used. Indeed the introduction of machines had to be made in such a way as not to displace too many hand pickers, and for a long time a united front prevailed. The pillars today are nearly all drawn by hand pick miners. With machine mining, specializing took place and instead of all the mining from placing down by one man, it was broken up into parts so that we now have the machine miner, the shooter and loader and the shot firer. A division of work and the introduction of a large amount of raw labor caused by the expansion of the coal trade led to a loss of individual responsibility for the quality of the coal produced. This was largely overcome by the appointing of coal inspectors whose duty it is to go through the mine and see to it that all work is done with the object of sending up coal of large size.

Where for any reason a coal seam seven or eight feet thick must be mined in the center or by what is known as "the fall and bench system," coal is more liable to be broken into small sizes. This system usually entails the use of a large amount of [illegible] shots. The amount of explosive [illegible] is greater in the aggregate and because of the [illegible] of the coal is much shattered. It sometimes happens that a great depth in the middle of a coal seam gives way under the vertical pressure, and there is no chance [illegible] the fall and bench system.

[illegible] Coal Carefully Supervised

Recent improvements have led to an examination of the coal before the screens and screening tables, the chutes both at the [illegible] and the shipping piers. Where the chutes [illegible] to stop changes were made to lessen the fall of the coal. Coal is fed to the picking [illegible] in front of all foreign material being removed.

Which is confined that coal from certain sections is dirty [illegible] the attention of the coal inspector is drawn to it. He immediately makes investigation in the mine [illegible] a more friable section of coal has been [illegible] explosive is being used or proper care has not been taken to clean the coal before it is sent out. Whatever the cause, it is ascertained and, if possible, it is removed.

Care is also taken to have all coal sent out of the mine in a dry condition. Where the grade is uniform and the seam regular this is easy; but where the floor becomes irregular and grading becomes difficult, water gathers. Coal from such places usually finds its way to the fire doors without passing over the screens and mixing with other coal.

A special coal inspector has been appointed in each colliery whose duty is to see that coal is sent out of the mine in the best possible condition. If at the screen tipple he finds the coal too small he proceeds at once to the section of the mine producing this coal and finds the cause. He reports to a chief Inspector who in turn passes a copy of this report to a regular mine Inspector who at once makes a closer investigation. In this way the collieries are all under special supervision and no practice tending towards the production of dirty coal or of inferior sizes can be carried on for even part of one day without falling under the notice of the management.

The coal companies of Nova Scotia have determined to supply coal in the best possible physical condition and of good quality and, from what we known of their plans, they will succeed.

METAL USED IN AUTOMOBILE CONSTRUCTION

Figures concerning 1921 consumption of materials by the automotive industry have just been published which disclose facts of unusual interest.

The automotive industry uses 1,464,000 tons of iron and steel a year—or approximately four per cent. of the total output of the United States. 43,250,000 pounds of aluminum were used in 1921 in manufacturing cars and trucks or twenty two per cent. of the total output of aluminum. The manufacture of automotive vehicles required the use of 83,125,000 pounds of copper—sixteen per cent. of all the copper mined in the country. One fifth of all the tin used in the United States is used in the automotive industry—some 12,510 tons a year. The Tanners Council estimates that 54,000,000 square feet of upholstering leather was our 1921 output, and of this amount 37,165,000 square feet were used in making comfortable seats for automobile and truck passengers. In addition, more than 88,000,000 square feet of imitation leather was used in upholstering (figure that out in acres for yourself).

Although the amount of wood on the average car does not seem to be worth mentioning at first glance, 315,800,000 board feet were used by this mushroom industry [illegible] year.

When one speaks of plate glass, one generally thinks of department store windows, but thirty per cent. of all the plate glass made in the country, or 16,500,000 square feet was used in manufacturing everything from roadsters to five ton buskies. It required nearly 6,000,000 gallons of paint and varnish to dress up our motor cars last year, and it took 16,000,000 pounds of hair and padding to make comfortable seats. Aside from these items 60 million pounds of lead, 3,100,000 pounds of nickel, 5,337,000 yards of upholstering cloth, and 15,340,000 yards of cotton material were some of the items in the raw material bill. From *The Industrial Digest*.

The Iron Ore on Belcher Islands

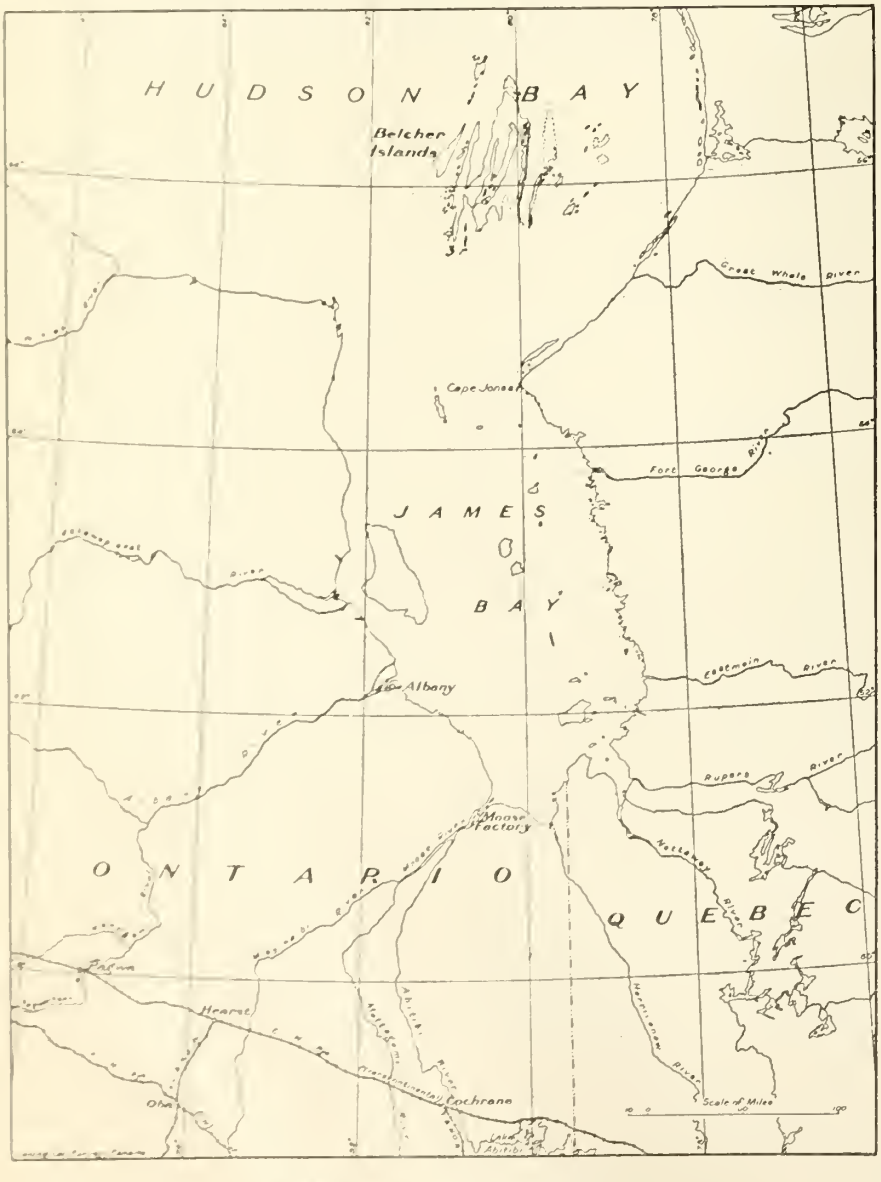
There has just been published by the Geological Survey, Ottawa, as Summary Report, 1921, Part E, *Iron-bearing Rocks of Belcher Islands, Hudson Bay, by G. A. Young.* This report of 61 pages, with three sketch maps, gives in its first three sections a comprehensive account of the geological occurrence of the extensive beds of iron formation, and in its final chapter a non-technical discussion of the economic features of the case.

The iron formation is of the banded siliceous type common in Ontario, 300 to 450 feet in thickness. It is underlain immediately by quartzite, and beneath that by slate and limestone. Above it in the sedimentary series is ellipsoidal basalt, from which it is separated, however, by a thick sill of diabase intruded uniformly at the juncture of iron formation and basalt. The rocks have been folded into a succession of antielines dipping at various angles up to the vertical, along the eroded tops of which the iron formation now is exposed. These north and south folds give to the Belcher Islands their elongated shape. It is suggested that the sedimentary rocks are Animikean in age.

Extent of Iron Formation

The exposures of iron formation and of iron ore are along the eastern edge of Flaherty Island, the prineipal island of the group, and a long peninsula that skirts its eastern side, and on two long islands that parallel this side at a distanee of from six to twelve miles. The parallel outerops of iron formation are parts of one bed, folded and then eroded so as to present these various exposures.

Dr. Young examined about 40 miles of the outerop of iron formation and observed it at a distanee, from a boat, for an additional length of 70 miles. From the outerop thus determined and from data as the dip of the strata he estimates that at least 150 square miles of land surface is underlain, at no great depth, by iron formation. Of the 40 miles of outerop examined, only 10 miles was sufficiently well exposed to allow of the unreserved statement that beds of iron were present or absent. With an unimportant exeeption, the general character of the iron formation was the same throughout.



By Courtesy of the Geological Survey.

BELCHER ISLANDS HUDSON BAY

Iron Formation underlies 150 square miles of land surface on the eastern side.

The Ore

"In eight areas examined on the several outcropping bands of iron formation highly ferruginous bands were found, and where the formation was fully exposed two or more such [illegible] In thickness the individual zones vary from 10 feet to 50 feet." Four representative samples across the zones gave iron from 35 to 45 [illegible] from 16 to 32%. A picked sample gave [illegible] and silica 24%. The ferruginous zones contain [illegible] capable of removal by hand picking, when the remainder of the zones would reach 50% iron [illegible] and the silica would be reduced to 20.

It is probable that these [illegible] zones owe their comparatively high content of iron to the character of the original deposition and not to any process of concentration such as causes the presence of commercial ore-deposits on the Mesabi range. However, as the character of the iron formation is not [illegible] distinction to some found in Ontario, such as to preclude the possibility of concentration to [illegible] it is possible that ore deposits of [illegible] grade occur, though now effectually concealed as a matter of drift.

In conclusion Dr. Young points out that since the sedimentary beds are essentially horizontal in character and regular in their disposition, the work of exploration "should consist of [illegible] examination of complete "natural or artificial [illegible] sections of the iron "formation [illegible] along the course of each "outcropping band. Such prospecting he recommends in preference to [illegible] diamond-drilling which in this case [illegible] only when the outcrops [illegible] examined thoroughly.

STRUCTURAL MATERIALS ALONG THE ST LAWRENCE

The Mines Branch, Ottawa, has recently published a *"Report on Structural Materials along the St Lawrence River, between Prescott, Ont., and Lachine, Que.,"* by Joseph Keele and [illegible] Cole. It is a volume of 120 pages, accompanied by [illegible] maps on a scale of a mile to the inch, showing the areas investigated, and well illustrated with photographs.

This report [illegible] the growing tendency toward inter-departmental co-operation in our administration at Ottawa. The Mines Branch undertook, in 1919, at the behest of the Dominion Power Board, an examination of the [illegible] of St. Lawrence for materials suitable for the building of [illegible] for the projected canal and power developments. The report of Messrs. Keele and Cole was so complete and thorough that the Dominion Power Board recommended its publication for general purposes.

The area covered [illegible] miles comprises a strip six to eight miles wide mostly along the north shore of the St. Lawrence. The geological map distinguishes between [illegible] rocks, sand, clay and gravel deposits, [illegible] swamp and peat. The materials [illegible] are limestone and clay for cement manufacture, [illegible] sand, gravel and crushed stone for [illegible] concrete.

Of the [illegible] for making cement, suitable clay is available [illegible] localities, but limestone of the requisite [illegible] occurs only in two localities, both near Cornwall, and [illegible] are commercially available only in [illegible] small quantities.

Sand [illegible] of the quality suitable for concrete are available only in small scattered deposits. Consequently recourse must be had to crushed limestone and screenings for the construction of any large works. Limestone for such a purpose can be got conveniently at numerous places on the shores of the river, and distributed cheaply in barges.

The report deals briefly with rock for road building and with materials for the making of brick. As brick and drain tile will be used to an increasing extent in the future, a number of promising localities for their manufacture are pointed out.

Deposits of pure silica occurring as sandstone at Beauharnois, Melocheville, Cascades Point and Isle Perrot, are described. Only at Melocheville is this material quarried at present. It will be used to an increasing extent as our industries develop.

Two possible sources of moulding sand for foundries are described, one about a mile north of Bainsville in Glengarry County, and the other 2½ miles west of Cardinal. Most of the moulding sand used in Ontario and Quebec at present is imported.

BENTONITE

A Species of Clay That Offers a Wide Field for Exploration

A non-metallic mineral which promises to be of considerable importance when it has been further investigated is the clay known as bentonite. It was first discovered in Canada in 1911 by Joseph Keele, ceramic engineer of the Department of Mines, at Camrose, Alberta, and later along the Red Deer river in Alberta and in the Nikola valley in British Columbia.

As described by Mr. Keele, bentonite, when freshly exposed, varies in colour from a light yellow to a light olive green, with a waxy lustre. It is exceedingly fine grained and has a soapy feeling when wet. In water it forms a jelly like mass. The research laboratories of Alberta University are reported to have established the fact that the presence of bentonite is responsible for the gumbo soil of western Canada. As it is capable of absorbing water to the extent of twelve times its bulk, it forms itself into a heavy sticky mass that renders roads almost impassable.

Wide Range of Uses

While its presence in the soil is undoubtedly a serious drawback in regard to transportation, bentonite has many valuable uses, notably as a filler in the manufacture of paper and textiles, in which it has advantages over kaolin, at present largely used. Other suggested uses are: soap making, in which it can [illegible] replace a portion of the soap substance; as a filler in rubber, leather, phonograph records, [illegible] and moulded insulations, as an ingredient in [illegible] and lime plasters, in ceramics, as a water softener and base for massage creams, as a carrier in [illegible] inks and as a substitute for fuller's earth.

The peculiar properties of bentonite [illegible] further study into its possibilities. And Messrs. E. A. Thompson and A. Sadler, of the Mines Branch of the Department of Mines, are making a more [illegible] investigation into the commercial value of the occurrences already reported and into further uses for the material.—*From "National Resources."*

Book Reviews

IRON ORE — Part 7 — Foreign America — Imperial Mineral Resources Bureau — 4s. 4½d., post free, from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2 — 136 pages.

This volume describes concisely the iron ore deposits of both Americas, with the exception of the British dominions and colonies, which were dealt with in Part 3. The chief producing country is, of course, the United States, but Cuba and Brazil have deposits of the first magnitude, in which development has been commenced, and a number of the South American republics have large, though mainly unexplored, supplies of high-grade ore.

The main facts of the iron-ore situation in the United States are so generally known that there is no need of repeating them here. It is noted once more that the high-grade ore of the Lake Superior field will last for only a few years, and that, if this field is to keep its ascendency, commercially successful process of "beneficiation" for low grade ores must be developed. The alternative to this is an enlarged use of the huge deposits of Alabama and the development of scattered deposits throughout the western and northeastern states.

That the growth of the United States steel industry has been developed for, and rests upon, the home market is made clear by the fact that exports of iron and steel are almost a negligible quantity, except during the abnormal war period. The United States does not influence seriously the British export of iron and steel. The former point has a moral for Canadians. We also have a huge territory in Alberta, protected by natural barriers from outside sources or supply, in which it may be possible to effect a successful industrial development alongside the great agricultural development that is now in prospect.

Cuban ore, though cheaply mined and transported, is not as yet used in great quantity. It has been used principally for the manufacture on the United States Atlantic seaboard of iron and steel for export. It is estimated that 1,000 million tons of commercial ore is available.

Mexico has numerous important deposits of iron ore, but only a small production. A development of deposits on the Pacific coast is forecasted.

In the Minas Geraes district of Brazil, superficial examination has determined the largest known reserve of high-grade hematite known in the world. A large part of the several thousand millions of tons available is almost pure oxide of iron, the silica being less than one per cent. and phosphorus and sulphur well below working limits. It is noted though, that the phosphorus is higher than is commonly supposed. The absence of coal has prevented the establishment of any important iron and steel industry. The government of Brazil wishes to encourage the home production of iron and steel, and an attempt to establish an electric smelting plant is under way.

Of the resources in iron ore of the other South American republics, little is known. Nowhere is coal available in sufficient quantity to stimulate a search for iron ore. Deposits have been found in all, particularly in Chile, where the high grade and accessibility of some of the ore has stimulated an attempt to establish an electric steel plant at Santiago.

IRON ORE — Part 8 — Foreign Asia — Imperial Mineral Resources Bureau — 2s. 9½d., post free, from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2 — 79 pages.

So far as determined up to the present, Asia is the least bountifully supplied with iron ore of all the continents. The principal known deposits are in China and Manchuria, and important ore-bodies have been located in the Philippine Islands, as well as those in Japan and in Korea, now part of the Japanese Empire.

The various iron ore deposits of China are estimated to contain 1,000 million tons. A large part of this is in the Yang-Tse valley, adjacent to the best coal to be had in eastern Asia, which is controlled by British capital. About one-half the known iron ore supply of China is now controlled by Japanese firms, which have been mainly responsible for the considerable growth of the iron and steel industry of north China during recent years.

The present annual consumption of iron per capita in China is less than 0.0008 ton. In the United States the figure is 0.25 ton. It is expected that the consumption per annum in China will increase rapidly during the next few years. If it were to reach the United States figure per capita, the known ore would last only five years.

Japan has ore reserves totalling 80 million tons. Most of her annual supply is brought from China, where she controls half the reserve available, as mentioned above. In spite of the disabilities due to poverty both of ore and of fuel, Japan is forging ahead as a producer of iron and steel.

In the Philippine Islands, in Sungao province, an area of 40 square miles along the coast contains lateritic ore of good quality, totalling 430 million tons. The nearest market at present in Japan, to which transportation is economically available.

In eastern Siberia, it is known in a vague way that immense deposits of iron ore occur, none of it being developed as yet. Throughout the rest of Asia, iron ore is widely distributed, but little is known of its economic possibilities.

VANADIUM. (1913-1919) — Imperial Mineral Resources Bureau — 7d., post free, from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2 — 19 pages.

This little report gives a resumé of the uses, preparation and occurrences of vanadium and its ores, with special attention to occurrences. The ever-increasing use of this rare metal to improve the quality of steel gives it an interest that is in proportion to the growing use of high-grade steels. Though the amount of workable ore available is small, vanadium is required to be added to steel in such minute quantities (0. 2 to 1.5 per cent.) to produce its whole effect that no large annual tonnage is needed. Its action in "scouring" steel by removing nitrogen and oxides as well as its direct alloying action are still the subjects of much study.

The chief, and at present almost the sole, source of commercial supply of vanadium is the Misasagra pat-

ronite deposits near Cerro de Pasco in Peru. The vanadiferous asphalt of these deposits when roasted to eliminate sulphur and carbon contains over 50 per cent. vanadium pentoxide. The next most important source of vanadium is the district in Utah and Colorado in which occur carnotite an ore of radium and vanadium, and roscoelite, the vanadium mica. These deposits, now owned by the Vanadium Corporation of America as are the Peruvian deposits, are not now being operated.

In the British Empire, vanadium ore is widely distributed, but has been found only in relatively unimportant amounts, mainly in conjunction with deposits of lead ore. At Broken Hill in Northern Rhodesia, hand-picking from the lead-zinc ore provides high-grade vanadium ore as a by-product. At Kaffirskraal in South Africa a deposit of vanadinite of fair size has been delineated. In South-West Africa in the Otavi district there has lately been a small but consistent production of mottramite from scattered deposits. In South Australia, carnotite occurs with titaniferous magnetite near Olary. An attempt made to use the deposit as a source of radium has been unsuccessful. The Taranaki iron-sands of New Zealand contain vanadium up to 0.34 per cent.

QUICKSILVER. (1913–1919.)—Imperial Mineral Resources Bureau.—1s. 1½d., post free, from H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2.—39 pages.

The use of quicksilver (mercury) is at present very limited, though it is one of the oldest known metals, and there is no prospect of the market expanding materially. Most of the world's annual supply (6 to 8 million pounds) comes from Almaden in Spain and Monte Amiata in Italy (formerly in Austria). "It is probable that "either locality, if worked to its full capacity, could "satisfy the world's demand for quicksilver for many "years to come."

The sulphides of mercury, cinnabar and cinnaharite, are the only commercial ores. The ore is roasted and the mercury thus released is distilled. The Almaden ore yields about 6.5 per cent. of the metal. In California, ore as low as 0.1 per cent. in mercury is worked. As a rule, workable ores of mercury occur in regions of Tertiary or recent volcanic activity.

Within the British Empire, Australia and New Zealand alone have produced mercury, and these only in small amount. In Canada the war-time scarcity promoted extensive exploration in an area at the western end of Kamloops Lake, British Columbia. The ore is estimated to contain 1 to 2 per cent. of mercury.

FINAL STATISTICS OF UNITED STATES COAL PRODUCTION IN 1921

Final statistics of production as reported to the United States Geological Survey by the bituminous operators show 415,000,000 net tons in 1921. The Survey's preliminary estimate published January 7, 1922, was 407,000,000 tons. The error in the estimate was thus 2.2 per cent.

Value

The value of the bituminous coal produced in 1921 was reported to be $1,179,000,000 as against $2,109,000,000 in 1920. The average value per ton f. o. b. mines declined from $3.50 in 1920 to $2.89.

Men Employed

Contrary to what might have been expected, the number of employees increased in 1921. There was less work but more men to share it. The total employed at bituminous mines was 663,754,—an increase of 24,000 men. This figure is not the average number of men at work at any one time, including the weeks or months when the mine may have been shut down; it is rather the number of men on the working force of the mine when it was in operation. Since the effect of the business depression upon the demand for coal did not become acute until February or March, the great majority of commercial mines got at least a few weeks operation during the year, and their working forces were thus counted in the total number of employees. By August, 1921, so many mines had closed down that the total number of men drawing wages in one week had fallen to somewhere between 500,000 and 530,000. Examination of the individual returns shows that in many districts the men laid off at small mines found employment at the larger mines. In fact, in some districts, such as Illinois and Pittsburgh, the coal mines employed men discharged by the factories or railroads. In still other districts, notably Maryland, the number employed decreased sharply.

The increase in number of employed was confined to the tonnage workers. The number of day-men decreased in almost every state. The total number of surface employees dropped from 110,000 to 96,000, and of underground day-men from 174,000 to 168,000.

Tons per man per day

This reduction in number of day workers was one cause of the remarkable increase in the output per man per day. In 1920 the average production per man employed per day worked, was 4.00 net tons,—a new record for the bituminous industry. Yet in 1921 the average rose to 4.20 tons, an increase of 5 percent. Other factors contributing to this increase, in addition to the change in proportion of day workers, were the natural tendency to restrict development work in a time of depression, an apparent tendency of the miners to work harder when running time is poor and, most important, a remarkable increase in the percentage of machine mined coal. Average productivity in a machine mine ranges from 20 to 30% above that in a mine where coal is undercut by hand or shot from the solid. Now in 1921 the proportion of coal mined by machines was 65.6% against 59.8% in 1920, and 55.9 in 1918.

Days Worked

Higher productivity per day tended to reduce the number of days worked. The average time worked by all of the bituminous mines was 149 days,—the lowest in the history of the bituminous industry. In the calculation of this average, as in earlier publications of the Geological Survey, the size of each mine is taken into account, and each affects the average in proportion to the number of men it employs.

Examination of the figures by states shows that the business depression was felt in every important coal producing region. Omitting the states of insignificant tonnage, such a California, Georgia, and North Carolina, the lowest number of days worked was 112 in Arkansas and the highest, 196 in Michigan. No important producing state reached the 200 day mark. In Illinois the average was 152 days, in Kentucky, 152, in Pennsylvania, 151; in West Virginia, 149, and in Alabama, 166.

News and Comments

BY ALEXANDER GRAY

Quebec Government Assists Asbestos Industry

In every way opportune was the decision of the Quebec Government to reduce the royalty (really an export tax) upon raw asbestos from 5 to 2½ per cent. The consumer was paying the tax, it is true, which formerly was 2½ per cent. Now the industry will be freer to move ahead and producers contemplating the establishment of fabricating plants will know exactly how they stand. Given this stabilizing influence, it is expected the mills will be enlarged and that manufacturers of asbestos materials will concentrate their enterprise to a greater extent in Quebec. So all's well that ends well.

Sir Mitchelson Meanders

Colossus has none the better of it with Sir Archibald Mitchelson, President of Porcupine Davidson Gold Mines, who is quoted in *The Globe* in this strain:

"The President stated that the outlook was certainly very favorable, and, while he did not claim at this stage that the Davidson Mine was another Hollinger, *he emphasized that it was on the same 'shear zone' formation*".

The italics are mine. Sir Archibald is Colossus and Leander combined. His bracketing is a trifle faulty—or is it his trajectory? These recurring comparisons of the Davidson and the Hollinger "shear zone", as closely akin, are unworthy of Pinner's Hall. Hollinger simply is not in it!

Clouds—and some Silver Linings

Kerr Lake and Temiskaming reflect what is inevitable unless outside investmen's mature with more rapidity. A deficit, after dividends, for Kerr Lake, notwithstanding there is a fi ly surplus, is not what those who know the record of the company care to see. Temiskaming has a substan ial stake in the Blue Diamond Coal venture, and elsewhere, but fruition is apt to be slow of accomplishment. As for the Castle-Threthewey statement, it was encouraging. A gain in the silver in reserve and the milling grade disclosed suggest what is contemplated—a more profitable output, and more of it, when cheaper power is available.

Castle-Trethewey Progressing

On balance the Cas le-Trethewey Mines may be said to have gained 338,000 ounces of silver for an operating loss of $7,693. That much is the excess of expenditure over receipts since the inception of the company in January last, reckoning to June 30. What high-grade was picked and shipped almost defrayed the cost of operations, and as the silver in the reserves now totals 640,000 ounces (at least that was the total in June) the company is fairly comfortable and is in a position to provide a concentrating plant. In the five months during which the company operations maintained, it is evident the management was more concerned with development than about shipments. Until hydro-electric power is available a milling program necessarily cannot be rushed.

Manager Kennedy is informative as to the development results. He points out the strong features and faultings, and is altoge'her optimistic. The details as presented by him are as follows:

40,399 ounces were shipped, being obtained by hand sorting from development rock. The ore shipped averaged 3,778 ounces per ton. Silver on hand amounts to 4,429 ounces, making a total production of 44,828 ounces of high grade, in addition to which 2,000 tons of 20-ounce ore were added to the dump. Ore reserves, which amount to 640,000 ounces, consist of 116,000 ounces in the dump and 524,000 ounces in the workings of Nos. 1 and 2 shafts.

Development work was confined to No. 2 shaft, and was mostly done on the 270-foot level, with generally better results than obtained in either of the upper levels. Seven veins have been opened up and important ore-shoots developed in veins 1, 2 and 3. In vein No. 1 an ore-shoot 75 feet long has been developed from the surface to the 270-foo' level, containing ore of 65 ounces per ton over a stoping width of 42 inches. In vein No. 2 ore has been opened up for 40 feet, assaying 50 ounces per ton over a stoping width of 42 inches. No. 3 vein has been opened up for 50 feet, assaying 50 ounces per ton over a stoping width of 42 inches. These ore bodies have been developed by raises and winzes and found to maintain their values below 'he 270-foot level.

Veins 4, 5 and 6 have persistently produced ore, but no continuous shoots have been developed. The favorable influence of flat-dipping faults paralleling the Keewatin-diabase contact is particularly noticeable below the 163-foot level. Mineralization and fracturing have proved to be more ex'ensive on the 270-foot level and veins 3, 4, 5 and 6 give every promise of becoming producers of high-grade ore.

The value of production is given at $28,000 in the profit and loss statement, this representing 40,000 ounces at 70c. Mine costs stand at $29,371, and administrative and general cos's $6,322, which shows an excess in expenditures of $7,693. The net liability for prior development expenditures undistributed and assumed under purchase agreement is given at $87,124, making a total of $94,818 carried to the balance sheet as deferred charges. Assets, current are $119,332, fixed $403,739; deferred charges $1,535,319, making a 'otal of $2,058,391. Current liabilities are given at $5,391, capital liabilities at $2,000,000, which is capital stock authorized and issued; and $53,000 contingent liabilities owing to former shareholders of Castle Mining Co., and payable only out of net profi's from operations.

METALLURGICAL WORKS IN CANADA

The Mines Branch, Ottawa, has published its annual list of metallurgical works, one of the series of such lists relative to the mining industry, all of which will be issued in due course. The list gives the address, location, products and managers of companies making iron and steel, nickel, copper, lead, tin, zinc, aluminium, antimony and magnesium, as well as silver-cobalt-nickel smelters and refineries and the customs concentrators in Ontario and British Columbia.

New Forge Blower

GIVES NEW MEANING TO TERM "FREE AIR"

BY D. M. McCLEAN, M. E. I. C.

Mine operators will undoubtedly be interested in a new device for blowing forge fires, etc., that recently has been introduced in Canada by The Canadian Ingersoll-Rand Company.

A tiny jet of high pressure air discharges into a bell-mouth nozzle leading to the forge and induces a flow of air from the atmosphere into the nozzle where it mingles with the expanding jet and is propelled into the pipe leading to the forge, providing the proper volume of air at a suitable pressure for the purpose.

In present practice, in mines, boiler shops, blacksmith shops, steel erection, ship yards and certain chemical and other processes, it is customary to take compressed air from the general supply line and throttle it down to a pressure of a few ounces before it reaches the forge tuyere or blow pipe of use. In rivet heating, for example, the ordinary small portable forge will require about 15 cubic feet of free air per minute to blow the fire. To compress this to the initial pressure of 100 lbs. will take the expenditure of approximately 7-1/2 horsepower. In constant daily use, this may mean a yearly cost for air for one forge of at least $300.

With the new blower or air transformer described herewith, the consumption of compressed air from the supply line is less than 2 cubic feet of free air per minute, requiring practically one-third of a horsepower, because the other 43 cubic feet required for the fire is drawn direct from the atmosphere. This represents a saving in dollars and cents per year per forge, other conditions being equal, of not less than $275 per forge. The term "free air" therefore, takes on a new and very important meaning.

Fig 2.

Forge Blower in Use

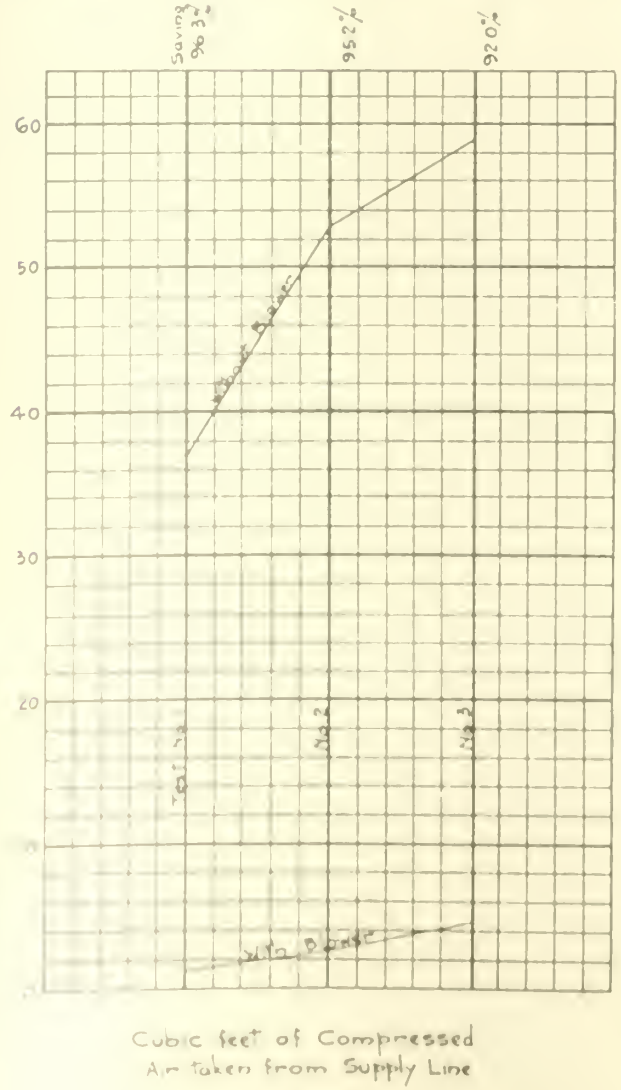


Fig. 1.

The chart, Fig. 1, shows graphically the results of three tests of forges operating with and without the blower. The space between the upper and the lower curves indicates the greatly lessened drain upon the compressed air supply, and the consequent savings are expressed in percentages at the top of the cut.

Test No. 1 was taken with a slow fire, No. 2 with a fairly hot fire and No. 3 with an intense fire. These percentages may also be considered as expressing the efficiency of the blower under the varying conditions, and they emphasize unmistakably the futility of the common practice of compressing the required quantity of air to a pressure of 80 to 100 lbs. and then throttling it down for use at a pressure of a few ounces.

These tests were taken with practically equal valve openings and consequent reduced pressure on the air nozzle. The results of tests with the blower connected to an orifice tank with low pressure [illegible] outlet to furnish resistance to draft and measure the output are shown in the tables appended.

Fig. 2 shows the general arrangement of the device. V is an ordinary needle valve regulating the flow of

compressed air. In ordinary operation, one quarter of a turn usually provides sufficient air for the work. After passing through the strainer S which retains all dust and dirt which might clog the device, the air reaches the special nozzle N and is discharged into the bell-mouth B which is connected to the forge.

The bell-mouth is cast solid with the strainer chamber, and ample space is provide for the access of free air as it is drawn into the bell-mouth. The strainer may easily be blown out to clean it by removing the plug at the bottom of the chamber. Home-made blowers resembling this device have often been made up from pipe fittings, but cannot attain anything like the results reached by this specially designed appliance, proportionated and adjusted for the best possible results. The standard blower of this type is designed to deliver the air at a pressure of 4 inches of water, but higher pressures may be reached by the use of specially designed jet nozzles.

In the tests mentioned above the actual air pressure in the screen chamber below the needle valve was taken. This is the same as the working pressure on the jet nozzle. The cost of this device is such a small fraction of the saving it ensures that it may be expected to have quite a wide application in its particular field.

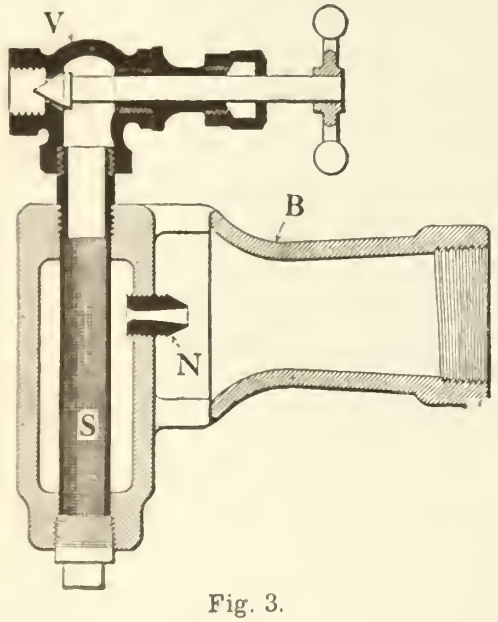

Fig. 3.

TEST No. 4.

RESULT OF TESTS OF NEW JERSEY BLOWER ON WIND BOX USING 1″ ORIFICE

Working Pressure on Jet Nozzle lbs. per sq. inch	High Pressure Air Used C. F. A. per minute.	Low Pressure in inches of water.	Free Air delivered C. F. M.	% of Air Induced
5	.96	.31	12.15	92
10	1.36	.72	18.5	92.8
15	1.67	1.00	21.8	92.3
20	1.93	1.25	24.4	92.2
30	2.52	1.84	29.6	91.5
40	3.07	2.38	33.6	90.8
50	3.64	2.87	36.9	90.2
60	4.20	3.14	38.6	89.2
70	4.75	3.61	41.4	88.7
80	5.3	4.12	44.2	88.
90	5.85	4.57	46.5	87.5
100	6.45	5.05	49.0	87.

With a 1″ Orifice the New Jersey Blower develops pressure or draft in excess of ordinary requirements for blowing forges. When pressure or resistance against which the Blower delivers is increased, this is at the expense of volume and also reduces the percentage of free air induced. The normal outlet of the Blower is 1¼″ giving a greater volume at a little lower draft pressure.

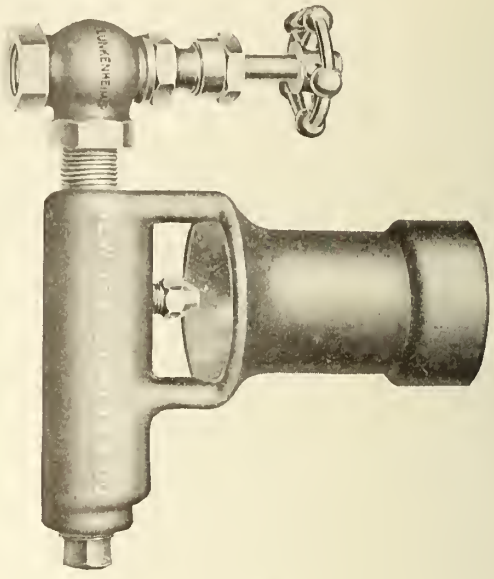

Fig. 4.

TEST No. 5.

RESULTS OF TESTS OF NEW JERSEY BLOWER IN WIND BOX USING 1¼″ ORIFICE

Working Pressure on Jet Nozzle lbs. per sq. inch.	High Pressure Air Used C. F. A. Per min.	Low Pressure in inches of water	Free Air delivered C. F. M.	% of Air Induced
5	.96	.29	18.3	94.8
10	1.36	.48	23.6	94.5
15	1.67	.67	28.0	94.0
20	1.93	.88	31.9	94.0
30	2.52	1.29	38.6	93.5
40	3.07	1.64	43.5	93.0
50	3.64	1.95	47.5	92.4
60	4.20	2.18	50.5	91.7
70	4.75	2.50	54.0	91.4
80	5.3	2.80	57.0	90.6
90	5.85	2.95	58.5	90.0
100	6.45	3.25	61.4	89.5

The resistance to flow or draft pressure required in an ordinary forge is somewhat less than for a nozzle of this size. With less resistance the flow is greater in volume. The working pressure on the jet is controlled by the needle valve and can be anything up to the full line pressure. In forge blowing the working pressure required is usually from 15 pounds and draft pressures of ½″ to 1″.

Copper-nickel alloy money, being of a yellowish colour and liable to earnish, is not diffieult to counterfeit; but coins of pure niekel metal are not subjeet to tarnish, and being of a bright white lustre, are practically proof against successful counterfeitures. Moreover, while copper-nickel is a comparatively soft alloy and consequently easy to work, pure Nickel is very hard, thereby offering almost insuperable diffieulty to successful counterfeiture, and in addition, pure niekel being subject to magnetic attraction, sparious coins composed of alloys can be immediately detected.

Steam From Electricity

By A. R. R. JONES

(Editor *Journal of Commerce*)

The production of steam by electricity seems, at first sight, a rather striking example of whimsical and ingenious paradox. But the electric steam generator has already achieved a certain, and is destined, one cannot doubt, to achieve a much wider, sphere of usefulness in its application of electric energy and its conversion to heat energy. For analysis of present conditions of energy production and conversion, accentuated by the recent, and, indeed, still continuing, dislocation of all kinds of productive activities, has shown that the electric steam generator has a very valuable place where hydro electric power is available which otherwise would be suffered to be idle or to go to waste.

It is not claimed that electricity can be produced to compete with coal for the making of steam at normal times and under conditions where electric power is sold on a kilowatt hour basis. But in a number of European countries possessing hydro electric power, the scarcity and high price of fuel, in recent years, have combined to favor the development and use of various methods, such as the electric steam generator, of generating steam by electricity. According to a very interesting paper on this subject by Mr. F. T. Kaelin, M.E.I.C., chief engineer to the Shawinigan Water and Power Company, read early this year before a joint meeting of the Montreal section of the Society of Chemical Industry, the Engineering Institute of Canada and the Canadian Institute of Mining and Metallurgy, there are more than three hundred installations known to exist in Italy, Switzerland, Sweden and France. In Canada and the United States a small number of generators have been in use for a short time.

Among the paper companies, and other industrial concerns, in the St. Maurice Valley district there have been quite a few installations of these appliances for the electrical generation of steam. The Laurentide Company has one of the largest installations thus far, and the Shawinigan Water and Power Company and the Laurentide Power Company must be benefiting largely by reason of their being able to dispose of their off peak load in this manner. For not only is the new apparatus very valuable to paper and other industrial companies by rendering them independent of coal in emergencies—in fact, with some industrial companies in the St. Maurice Valley, coal is now said to be playing quite a secondary part in the turning of wheels—but it is also giving power companies a market for their surplus current at a figure sufficient at least to pay operating and carrying charges.

Power companies have had cause, in these recent times of industrial depression, to consider the problem of the disposal of their surplus power. This power they can obviously afford to sell cheaper while there is no other market for it, in preference to allowing it to run to waste, but it must yet be emphasized that they could not afford to develop hydro electric power for the main purpose of generating steam in competition with coal. Thus the problem that has been confronting them has been to find a use for their surplus power, which would not require any expensive installation, new machinery or additional apparatus. And a solution, or part solution, of this problem has unquestionably been found in the turning of electric power into heat in the form of steam which is used very largely in many industries, and especially in the pulp and paper industry.

Some of the installations in operation today may be considered as temporary, and as, in fact, owing their existence to exceptional industrial and other conditions. At the same time, there can be little doubt that there are many cases where the electric steam generator has made for itself a valuable place and one of permanent usefulness at such times as there is power available from the power companies. In the paper from which we have quoted, Mr. Kaelin suggests that it may even be feasible to use only night power by means of close cooperation of the power company with the power user, and in virtue of the fact that the starting and stopping of electric steam generators take only a few minutes. These are points which, as he says, render the steam generator a very flexible apparatus and make it very useful for the conversion of electric energy, at any time, at short notice and at extremely low cost, into valuable heat energy.

In the electric steam generators all electric energy is converted into heat energy, and the electric current passes through a resistance, either of metal or formed by the water to be evaporated. They have been built during the last ten years in capacities up to 1,000 kilowatt, and only within the last two years sizes of 2,000 kilowatt and more have made their appearance. Steam generators can be divided, as appears from what we have just said as to the passage of the electric current, into two main and distinct classes: First, generators in which the electric current passes through a combination of metallic resistors; and secondly, generators in which the water itself forms the electric resistance. In his paper above referred to, Mr. Kaelin emphasizes the outstanding advantages of the water resistance type, as compared with other types, as consisting in simplicity of construction, compactness, easy control, and its very low cost per kilowatt capacity which is very often the determining factor, especially for temporary installations, or where that rate power is consumed to flatten the load factor of an industrial plant.

Among the other advantages of the electric steam generator over the usual coal fired boiler, Mr. Kaelin mentions the fact that any interruption to feed water supply simply means the shutting down of the generator and does not in

troduce any danger. The steam generator is equipped with the usual steam safety valves, and can, in addition, be supplied with an automatic blow-off valve which discharges the water and thereby shuts down the generator, should the pressure go beyond a fixed limit. Other safety devices consist in relay protection of the electric circuit in case of short circuit, unbalancing or ground on the electric system, and a trip for the automatic oil switch, which will interrupt power and therefore the steam supply. Accordingly, the operation of the steam generator may be said to be as safe as, if not safer than, that of the ordinary boiler, and the insurance companies have no hesitation in accepting insurance on the apparatus in the usual manner.

What we have said will suffice to show something of the importance to industry of the electric steam generator and its possibilities. In the near future we shall publish a special article going into the whole subject in considerable detail.

POSITIONS VACANT

The Secretary of the Civil Service Commission, Ottawa has given notice of the appointment of the following. Particulars and forms for application can be had from him.

4606. A Junior Chemist, Ore Dressing and Metallurgy Division, Department of Mines, Ottawa, Ontario, at a salary of $1,680 per annum, which will be increased upon recommendation for efficient service at the rate of $120 per annum, until a maximum of $2,040 has been reached. This salary will be supplemented by whatever bonus may be provided by law.

4607. An Inspector of Petroleum and Natural Gas Operations, Mining Lands and Yukon Branch, Department of the Interior, Calgary, Alta., at an initial salary of $2,100 per annum which will be increased upon recommendation for efficient service at the rate of $120 per annum, until a maximum of $2,580 has been reached. This salary will be supplemented by whatever bonus may be provided by law.

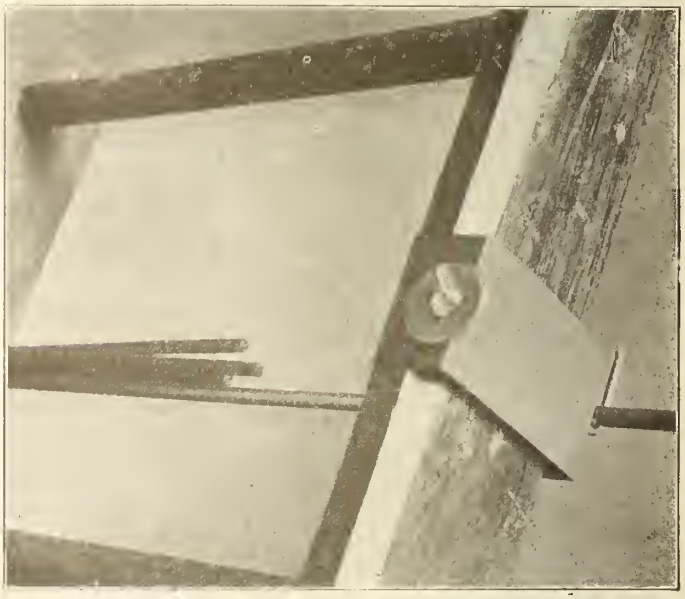
NEW MAP

The Department of Mines, Toronto, has published a little map on a scale of 4 miles to an inch, of the Watabeag Lake area, which includes 15 townships extending westward from Sesekinika and Ramore stations on the T. and N. O. Ry. to Michie, Timmins and Sheraton Townships. It outlines the geology of this area, which is, briefly, two larges areas of Keewatin rocks intruded by Algoman granite, with an area of Cobalt sedimentarics near the railway. A large part of the area is heavily drift-covered. This map will be followed in due course by one on a larger scale geologically coloured and showing greater detail, to accompany Mr. D. G. H. Wright's report on the district. The eastern tier of townships has been mapped previously, but has been included in this key map for the purpose of indicating the position of the area relative to the railway. Copies of the map are available on application to the Department of Mines, Toronto, or to the several Recording offices.

A LADDER VISE ATTACHMENT

For want of a better name the attachment shown in the photo is called a ladder vise, because it enables work to be tightened to the side of a ladder in a manner similar to a bench vise.

Often it is a difficult operation to drag out a particular length of steel from a rack running along the storeroom wall, especially if the size required lies near the bottom of a pile or is some distance from the floor, as most of the smaller diameters usually are. When the whole length of the piece is required there is no alternative, of course, but to pull it all out. It is when only a certain length is required that the usefulness of the device illustrated is shown, for by its use the stock can be sawed off without removal from the rack.



To make the vise, a piece of sheet-iron is cut and bent to fit the side of ladder, so that it will slide up and down, the ends being bent inwards but left short enough to clear the rungs. Next a hole is drilled or punched for a rod which is bent at right angles at one end of the iron, after which the wing nut is tightened together with a washer rather large in proportion to the nut, forming the means for tightening the vise in place.

When it is desired to saw a length of rod, the ladder is placed in a convenient position and the particular rod wanted pulled out from the rest a distance a little longer than the length required. The vise is then slid to position and the work inserted between the bent rod and the iron, after which the wing nut is tightened and the piece sawed off in the usual manner with a hack-saw.

Easy to make and simple to operate, this attachment holds a rod securely while being sawed, rapid adjustment being effected by the single nut tightening the work in the vise and the vise to the ladder at the same time.—Harry Moore, Montreal.

The bituminous sand beds intersected for a distance of 73 miles by the Athabaska River are 150 to 200 feet thick and are estimated to cover an extent of 10,000 square miles. These beds comprise, therefore, not only the largest known deposits of asphaltic material, but one of the world's largest accumulations of carbonaceous material.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

(Special Correspondence)

EXPRESS RATES ON BULLION.—Partly due to the efforts of the Ontario Mining Association, the Express Companies have granted a reduction in the carrying charges for gold and silver bullion. While the reduction on gold bullion is comparatively small, a substantial saving has been effected on silver bullion. The price from Cobalt to either St. John or Halifax will be $5.60 per $1,000, as compared with a rate of $7.90 now in force. On gold bullion from Porcupine and Swastika to Denver, Colorado, a reduction of 60 cents has been made, the new rates being $5.45 and $5.15 per $1,000. To Ottawa the new rates will be $2.10 and $1.80, a reduction of 25 cents and 20 cents respectively.

HIGH GRADING.—Further arrests have been made in connection with the effort to stamp out high-grading in the Northern Ontario gold camps. A man named E. Belanger from South Porcupine was caught in North Bay and was found to have in his possession 65 pounds of high grade ore, estimated to be worth $100 per pound. Several Italians in Porcupine, employees of the Dome, were also arrested in connection with this lot. Police officials claim that three separate rings have been operating, and police activities to date have resulted in the arrest of members from each of those gangs. It is understood that further arrests are liable to follow in the near future.

KELLEY.—It is stated that the Keeley has found one of the richest silver veins ever encountered in Northern Ontario. The discovery was made on the 4th level of the Woods contact and on plunge the ore is 12 inches in width, and of an extremely high grade. The company is maintaining a large production and in September the output was [illegible].

NIPISSING.—During the month of September the Nipissing mined ore estimated as value of $194,000 and shipped bullion and products of an estimated net value of $[illegible]. The low-grade mill treated 6,834 tons and the high-grade mill 201 tons, while the refinery shipped [illegible] ounces of bullion.

MCKINLEY DARRAGH.—During the month of September the McKinley Darragh produced 52,000 ounces, some of which was obtained from the vein recently discovered. The vein on this property is of substantial width, but [illegible].

O'BRIEN.—The O'Brien group lost its mill by fire a couple of months ago, but concluded a deal for the purchase of the Castle mill at a price understood to be $75,000. The Keeley Company has a bond issue of $150,000 on which the interest was in default and it is understood that an offer was made to the court under authority [illegible].

[illegible].—The Consolidated built the mining plant on the [illegible] was destroyed by the big fire. It is also said that the Consolidated negotiations for the Beaver will soon be concluded. The Beaver has some very promising features on the lower contact, but has not sufficient money to undertake a development.

CASTLE.—The report of the four months ending June 30th, shows a production of 44,000 ounces, valued at $28,000, and expenditure of $35,700, leaving a deficit of $7,700. The report states, however, that during this period an additional 338,000 ounces of silver was put in sight, and ore reserves now stand at 640,000 ounces. Drifting on the 270-foot level has shown the best result of any part of the mine. The financial statement shows current assets of $119,332 and current liabilities of only $5,391. A further sum of $87,124, representing liabilities for development expenditures which have not been distributed, makes a total of $91,818 on the debit side of the Balance Sheet.

TRETHEWEY.—The annual report of the Trethewey for the year ending June 30th shows that the Castle has assumed the old Trethewey's liabilities of $87,124. The only asset that the Trethewey now has is 400,000 shares of Castle stock. Expenditures for the year were $12,900, with no revenue.

EVERETT.—Underground development work has been started on the Everett, which adjoins the Castle. Operations are being conducted from the original Castle shaft, which was sunk close to the Everett boundary, and crosscutting has been started on the 175 foot level.

KIRKLAND MILLS IDLE.—Operations in the Kirkland mines are still confined to pumping, and it will probably be some time early in November before sufficient power will be available to permit the mines and mills resuming.

REBUILDING POWER LINES.—A few days after the big fire that destroyed the transmission line of the Northern Ontario Light and Power Company, it was thought that a temporary line could be made which would permit power being turned on in two weeks. The damage, however, proved to be greater than originally estimated, and the power company decided to make a permanent job of replacing the burned section instead of trying to get power over a temporary line.

POWER THROUGHOUT WINTER.—Due to the extremely dry season, operators have been somewhat doubtful about the supply of power during the winter. The main supply is generated at the Matabitchewan plant, but this year the company has installed another storage dam on Rabbit Lake and feels that there will be sufficient water to carry on operations throughout the winter without any curtailment of power.

TOUGH OAKES.—A recent official statement of the development work on the Tough Oakes reports that 34 feet of drifting has been done on the new vein found on the 4th level, and that the average assay is $11.00 over a width of 50 inches. No information has been given out regarding the milling results, but the Ontario Department of Mines report for the first six months of the present year shows that the Tough Oakes ore averaged less than $5.00 per ton. The mill had only been started a short while, however, and it is possible that during the turning up process low grade ore was [illegible].

LEBEL LODE.—The Lebel Lode is negotiating for the underwriting of a block of treasury stock, and in the meantime work on the property has been stopped.

Continental.—The recent offering of 250,000 shares of Continental Mines Limited has been oversubscribed. This company owns 27 claims in the Kirkland Lake district and will now have $1,000,000 in the Treasury, which will be ample to finance the proposed plans which the company has under consideration.

Pancake Lake.—Development work on the new find of the Pancake Lake property of the Crown Reserve continues to give good results. On the adjoining property the Associated Gold Fields has just completed a 1000-foot diamond drill hole, but no information is available regarding the results obtained.

West Dome Lake.—Notices have been sent to shareholders regarding the completion of the Consolidated West Dome Lake merger, and they are asked to turn in their shares to the liquidator in order to permit of the distribution of the stock on the basis of one share for each two shares of the old stock. Dome Lake officials have also asked the shareholders to contribute 1 cent per share to pay off the $30,000 debt owing to the Hudson Bay Mines. The new merger has a capital of $5,000,000, of which 1,750,000 shares are in the treasury. This has been underwritten on a graduated scale from 20 to 60 cents per share, and will net the company approximately 40 cents a share.

Dome.—An unsually rich discovery has been reported on the 7th level of the Dome, and it is stated that high grade ore is being bagged and shipped direct to the refinery. The company continues to maintain a high production and the October output will be approximately that of September, which amounted to $423,000.

Clifton.—The Clifton has its small mill in shape to commence operations, but it is understood that power will not be available until there have been heavy rains or until the Sturgeon Falls plant is completed.

McIntyre.—The report of the McIntyre for the three months ending September 30th shows gross earnings of $585,868 and net earnings, before allowance for plant depreciation, of $268,035. Production for the quarter is considerably in excess of that for the corresponding quarter of the previous year, and is considered particularly gratifying in view of the fact that very little benefit was obtained from the new mill additions. The full benefit will be reflected in the quarter ending December 31st.

Davidson.—A shareholders meeting of the Porcupine-Davidson was recently held in London, England, at which it was announced that within eighteen months it was expected to have the 500-ton mill built and the new 1000-foot shaft completed. The estimated expenditure for this is £100,000, and an agreement has been entered into whereby the money will be loaned for a period of two years with interest at 5 per cent.

NOVA SCOTIA

Steel Plant Output.—With a working force of 3050 men, the ingot-output of the Sydney steel works equals the output of the years when the number of men employed ran close to 3800. The gain is, however, not altogether due to better management. The kind of material being turned out accounts for a small part of it. A record day last week show 1,101 tons, the highest in the whole 22 years of operation.

Galvanizing Plant.—A new galvanizing unit is to be built at the Sydney Steel plant to take the place of the one now running. It will have a daily output of 80 tons, being twice the capacity of the present mill. The demand for wire and wire products has increased very much of late and bids fair to out-run the supply, but the new unit will take care of all the needs of the wire trade.

Rail Order.—The order for 25,000 tons of 100-pound steel rails for delivery next spring placed with the British Empire Steel Corporation by the Grand Trunk Railway, will keep the rail mill busy throughout the winter, present orders being sufficient for brisk business up to Christmas.

Electric Undercutter.—The Sullivan electric undercutting machine is being used in No. 24 colliery, a comparatively new mine. This is the first electric undercutter in the Glace Bay district and its work will be watched with interest by all mining men, as it marks a departure in cutting coal in Glace Bay collieries. The Dominion Coal Company plans to cut all coal in the future by electric power and has been preparing for the change ever since the British Empire Steel Corporation took practical form.

BRITISH COLUMBIA

Mackenzie River.—Professor M. Y. Williams of the University of British Columbia returned recently from a trip to the McKenzie River basin where he was in charge of a geological survey party. He left Fort Norman on September 4th and says that the only persons he saw there were the employees of the Imperial Oil Company and some Indians. The white posts of the claims staker were spread over the country for miles, tombstones of a vanished hope. Practically all these claims have been abandoned as the high rental demanded by the Government made it impracticable for the lessees to retain them. Even the Fort Norman Syndicate's well, which struck gas at 1500 ft.—"the only well put down by an outside company"—has been abandoned.

"Take the case of a man who staked the limit," said Professor Williams "a limit of four square miles. At a yearly rental of 50 cents an acre this would cost him annually $1200. There were many who paid this amount to hold their claims for a year, believing that within a twelve month they could dispose of them at a huge profit. Their claims have gone the way of those who were satisfied with smaller holdings."

The Imperial Oil Company alone continues the quest, but is not hurrying about it. The Discovery well, the first gusher to be brought in, has been deepened and a greater flow of oil has been struck, but the total flow is estimated at only 75 barrels a day. The Company is still working at the other four wells which were started last year, but nothing more has been found. As Professor Williams was coming up the McKenzie toward home he met two new crews going in to replace the oil drillers who were leaving the country. These crews were picked men from the Petrolea Oil Field in charge of Angus Sutherland, a veteran driller. They will sacrifice the young months of winter in order to be early at work next spring, for the frozen lakes and rivers do not permit entry through the country until June.

In his comments on the Mineral Resources of the North, Professor William refers to the Nathinna River, which is on the direct route to the Yukon. He states that this river and the district contiguous to it offers a splendid field for exploration. It is supposed to conceal in its bed enough gold to pay off the national debt. A large number of prospectors went in to this section

this year. Guarding the mouth of the river like a silent, sentinel stands the Nathlinina Butte, 4,000 feet above the stream, which is bordered by mountains for its full length.

Cedar Creek.—The Del Ecuador Mines Co., Limited holders of four placer gold leases on Cedar Creek, Cariboo, B. C., valued at $100,000, has gone into voluntary liquidation to meet creditors claims of $17,000. The Company was incorporated in 1897 and with the recent revival of activity in the Cedar Creek District resumed operations this year.

Mayo.—Captain George Black, M. P. has returned after spending the summer in the Yukon Territory. Referring to the Mayo Camp he states that the Keno Hill property shipped 3,100 tons of high grade ore to the Selby Smelter at San Francisco during the summer. The experiment of transporting ore from the mine to river boats by tractor trucks, which carry from 25 to 30 tons a load, is proving satisfactory. Captain Black also announced that important strikes have been made in the Beaver Creek district, about 50 miles from Mayo. Not much was known about them yet but there were indications that the whole district was richly mineralized and several outfits had been taken in to continue work all winter. He said that next summer would see both the Keno Hill and Alaska Treadwell Co. installing reduction plants for the treatment of lowgrade ore. At present only ore running from $100 a ton up was being shipped and great dumps of the lower grade had been accumulating. Many of the placer companies, which have not been operating since early in the war, are planning to resume work next year. He expects to see a remarkable recovery on the part of the Yukon in point of mineral production.

Portland Canal.—The directors and shareholders of the American Mining & Milling Co. who recently visited their property on Fish Creek, Portland Canal District, appear thoroughly satisfied with the showings made and the progress of development. W. R. Tonkin, who is in charge of the work, took his visitors over the camp and Mr. Grant Mahood, President, afterwards stated that it was the intention immediately to make surveys for an aerial tramway to be built in the spring. This will be from a mile to a mile and a quarter in length, coming from the mine to the Salmon River wagon road. Plans also have been made for the installation of a concentration plant capable of handling 100 tons of ore a day. Brothers & Company, of New York, are reported to have undertaken the financing of work necessary on the development of the Daly Alaska group of mineral claims, Portland Canal.

A [illegible] grade ore is reported as having been made on the Alaska Premier, samples of the ore giving returns of [illegible] gold and 26.0 ozs. in silver.

A [illegible] tunnel on the Big Missouri. It [illegible] 60 ft. in good ore. The intention is to [illegible] 200 or 250 ft. A blower is being used for ventilation.

The Consolidated Western Fuel Corporation dropped to E. J. [illegible] and associates of Seattle, Washington. The property is situated on the east side of the Portland Canal [illegible] of some 3,000 or 3,500 ft. There are [illegible] and defined leads, all of which have been [illegible] and good values are showing up in gold and silver.

Trail.—The receipts at the Trail Smelter, Consolidated Mining & Smelting Co. for the first seven days of October were 8776 tons. Among the contributors were the Bosun, Sandon, B. C., 18 tons; Knob Hill, Republic Hill, Republic, 118; Lanark, Lawrie, 23; Metallic group, Silverton 15; Noble Five, Sandon, 87; Northport Smelter, 54; Ottawa, Slocan City, 15; Paradise, Lake Windermere, 41; Quilp, Republic 160; Silversmith, Sandon, 175; Silver Hoard, insworth, 38; Surprise , Republic, 105; Standard, Silverton, 183; Utica, Adamant 47; Van Roi, Silverton 25, and Neosho, Ainsworth 11. The latter is the first shipment made from this property. The Company properties have shipped so far this year to the corporation smelter 304,718 tons of ore which is an exceptionally high mark.

Oil Wells In Alberta.—J. R. Court, of London, Eng. Director of the Spartan Oil Co. Ltd. is in Western Canada investigating conditions in the Coutts and Wainwright oil fields. Mr. Court is said to represent British financiers and to be commissioned to obtain for them the facts regarding existing oil condition in the Province of Alberta. "Drilling in the Coutts properties of the Spartan Company will start immediately", Mr. Court stated. "We are drilling one well in Montana and also expect to commence operations quite extensively on the Canadian side. We have just shipped 7 carloads of equipment and casing to Coutts, Alberta, in order that an early start may be made in the exploration of a field approximately 10,000 acres, which the company has under option."

Smithers.—J. F. Duthie, of J. F. Duthie & Company, Seattle, Washington states that a mining plant consisting of compressors, drills etc. will be shipped to Smithers, B. C. to facilitate further development on the Aldrich, Henderson, and White Swan groups of silver-lead claims, Hudson Bay Mountain. He states that surveyors are now working on the mountain to permit the drawing up of plans for the creation of an aerial tramway from the mine to the Smithers Railway Depot. One hundred tons of silver-lead ore is ready and will be shipped on the settlement of the freight rates question.

Vancouver Meeting C. I. M. & M. The annual meeting of the British Columbia Division of the Canadian Institute of Mining and Metallurgy will be held at Vancouver, B. C. starting November 15th next. There will be the usual sessions and the arrangements thus far made assure a programme of unusual interest. Plans have been made to enable delegates to visit some of the operating coal mines of Vancouver Island.

B. C. Coal in September.—Although the collieries of British Columbia have not been working at the same high pressure recently as was the case in August, there was little lost time in the month of September, the total production for that period being 267,355 tons. The Herewood Mine, Canadian Western Fuel Corporation, lost two days but, apart from this, there was no evidence of slackness. There was, however, a distinct slowing up on the Island and in the Nicolas Princeton fields. As for the Crow's Nest, the returns show that it has not taken long for the operators to get back almost to normal in point of output.

The Canadian Western Fuel Corporation dropped from 85,282 tons in August to [illegible] in September; the Canadian Collieries from 18,118 to 39,108 at [illegible] 21,044 to 18,823 at Extension; and 7,117 to [illegible] at South Wellington; the Granby Companies from [illegible] to 21,115; and the Nanoose Wellington from 10,31[illegible]

to 2,851. The same tendency is shown by statistics relating to the Nicolas Princeton Collieries, the Middlesboro Colliery from 1,540 tons to 7,135; the Fleming Coal Co. from 1,676 to 3,894, and the Coalmont from 18,059 to 14,599.

The rapidity with which the Crow's Nest Pass Collieries have got back on their feet after the strike lasting from April to September is remarkable. The Coal Creek Mines in March last produced 56,780 tons and last month their output was 36,997 tons. There were mined at Michel last March 33,240 tons and the figures for September are 31,228. The Corbin Coal and Coke Co. has 6,703 tons to its credit for September. Last March it was 7,430 tons. This mine, however, was not entirely closed down over the whole period of the strike, having an output of 3,554 tons in April and 179 tons in May.

A DOUBLE DRUM COMPRESSED AIR HOIST

A portable hoist, designed primarily for more convenient, economical and effective use in hauling ore scrapers or "slushing" than can be secured with the single drum hoist of this type, is announced by the Sullivan Machinery Company, Chicago, Ills., and is known as Type "HDA." In the double drum hoist, the "Turbinair" motor, in its casing, is supported on a central standard with a broad frame or foot, and supplies power to the two hoisting drums, each 10 3-4 inches in diameter by 5 1-8 inch face, which enclose the motor.

The capacity of this hoist is the same as that of the single drum type. Either drum is capable of lifting 2,000 lb. dead weight vertically, with 75 lb. of air pressure at a speed of 110 ft. per minute. This hoist has the same economy of air consumption as the single drum machine. Sufficient air can be supplied the machine through a 3-4 inch hose line to develop the machine's rating of 6 1-2 H. P.

In "slushing" work the live or hauling rope is attached to one drum and the tail rope or return rope to the other drum. By means of a suitably placed snatch block or arrangement of sheaves, the tail rope is paid off the second drum as the load comes in on the first, and when the scraper has been dumped the process is reversed, the clutch being thrown out on the live rope drum and in on the tail rope drum to haul the scraper back to the loading point.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

EDITORIAL

Every Canadian must wish the utmost success to the efforts now being made to develop the gold mining industry in the Dominion, but not by the plan of the modern miner who, unlike the ancient miner, begins by opening a broker's office on a leading thoroughfare instead of a tunnel in a mineralized hillside.—A. R. Selwyn —1897.

WILL THE COAL MINERS HOLD UP THE PUBLIC?

The president of district eighteen, United Mine Workers of America, is quoted in a press despatch as announcing that at the expiry of their agreement with the operators on March 31st next, they will demand not only the continuance of the present rates of pay, but a six hour day and a five day week. Thus do the coal miners of Alberta and eastern British Columbia throw down the gage of battle before their employers, the coal operators. They do this openly and deliberately, with a full knowledge of what their challenge involves. There are rumours of a similar move to be made by the coal miners of the United States at their conferences to be held soon. They too are ready to renew a fight of which they have won the first round.

It is probable that none of these unions of coal miners realize clearly a fact that is as yet only dimly seen by the general public, and in fact has not yet become even dimly visible to the vast majority. The coal miners have determined deliberately to constitute themselves a privileged class on this continent, and demand it as a right that they be paid for their labour at a rate quite out of proportion to the service they render the whole people of the continent. The terms under which they propose to labour in the mines would afford them a living at the expense of less effort than will support the average man and his family under the conditions at present prevailing in Canada and the United States. They implicitly propose that other classes of labour and professional men shall expend the remainder of effort necessary to provide them (the coal miners) with a comfortable living. Their present demands mean that the rest of the community of all callings, are to work longer hours that the miners may have two days of rest in seven and an exceptionally short period of labour on the other five days. The coal miners propose a measure that will turn them into the human leeches they profess to decry, against whose supposed domination, as capitalists, the present ultimatum is directed.

Will the public allow itself to be held up, as was done recently when the coal operators acceded to the demands of the miners? Will the case of the public remain virtually unrepresented when the other two parties to the dispute align their arguments next spring? Shall we, the owners of the natural resource that is the physical basis of the dispute, allow our agents, the operators and the miners, to decide their differences without reference to our undoubted and inalienable rights? Put in this light, the conclusion is obvious.

Unfortunately the general public, which alone can provide and enforce a just decision in this triangular dispute, is not as yet sufficiently aware of its responsibility to act in the decided way the occasion requires. There are glimmerings of interest in the dispute in certain quarters, but the issue is as yet grasped clearly by only a very few. It is incumbent upon these few to act, and to act promptly. The public press is the principal and most effective means of educating the public rapidly and effectively in such a case. We hope that publicists and the press will take hold of this most important question and employ all the means at their command to prepare the public's brief. Only thus will a purely selfish decision be avoided. Only thus will British justice be upheld in its high place in our land.

CANADIAN SOAPSTONE PRODUCTION

There is in Canada an increasing annual consumption of blocks or bricks of soapstone, which are used to line the "smelting" furnaces of sulphate pulp mills. These mills make the tough "kraft" paper, which is growing rapidly in popularity, and there are now over thirty of them in Canada. The liquor from the digesters in the sulphate pulp mills containing the resinous materials extracted from the wood and the chief chemical reagent, as sodium sulphate, is charged into the "smelting" furnace, where the carbonaceous materials are burned out and the sulphate is reduced to sulphide and thus regenerated.

The chief requirements for the lining of this furnace are that it should remain unfused at the high temperatures used (2000 deg. Fahr. or over) and that it should remain unattacked by the fused sodium sulphide in the bottom. Bricks of chrome and of talc fulfil these conditions and

the latter is so much the less expensive that it is generally used. It can be quarried so cheaply and then fashioned so easily by sawing into the shapes required that its use for the purpose seems secure for a long time to come.

Heretofore the soapstone blocks used in Canada have been imported, principally from the United States. Now there is a consistent Canadian production. During the past summer Mr. Louis Cyr has been quarying and shipping the blocks for Canadian mills from his property two miles northeast of Robertson, Quebec, in the Thetford district of the Eastern Townships. The quality of the soapstone in these blocks is said to be better than those usually imported.

Here is native Canadian enterprise of the right sort, operating on a small scale, to be sure, but constituting an example of progress that can be duplicated a hundred times and that will, in the aggregate, means much to Canada's mineral industry. In a somewhat similar way there was inaugurated years ago the use of soapstone in the form of talc at Madoc, Ontario, an undertaking that has grown with the years to occupy a prominent place in the world's talc industry. It is not too much to hope that Canadian soapstone may enjoy eventually the reputation of Canadian talc.

AN ADVOCATE OF CAUTION

Mr. C. M. Campbell makes today, in these pages an unusually effective contribution to the discussion on the general dimensions of Canada's mineral resources that he originated last spring. He has examined critically statistics that most of us have accepted without question, and finds that they cannot be accepted at face value. He has been at great pains not only to analyze these statistics, but to collect and collate additional facts that have a vital bearing on the subject. He shows (what many of us suspected, but none other of us took the trouble to prove) that the mining industry of Canada does not comprise such a large fraction of our total national production and is not so important to our railways as certain over-all statistics would lead us to believe.

Without accepting all of Mr. Campbell's deductions from the facts he presents so clearly, we must realize the truth of most of what he says, and shall do well to shape our actions accordingly. The fact that such a large proportion of mineral products, notably iron ore and coal, carried by our railways is of foreign origin should stimulate us to replace it as far as possible with Canadian products. If we see clearly the dimensions of the sum lost annually through the export of raw minerals rather than the products of their manufacture, we will do our utmost to remedy the case to our own gain. An unclouded view of our National Railway lines shows thousands of miles built before their time; yet it shows also the lands they traverse, awaiting the prospector and the miner, to whom they promise much. If we see an annual wastage of our meagre capital resources in money due to misdirected enthusiasm, we must take pains in future to direct both capital and enthusiasm into more profitable channels.

As we pointed out some months ago in these columns, this discussion, in which Mr. Campbell and Dr. Corless consider themselves the proponents of opposing principles, elucidates, in our opinion, two different aspects of one and the same question, each of which is useful and indeed necessary in its own proper sphere. Without the optimism that has been the guiding principle of Dr. Corless' public utterances of late, there would be no prospecting, no development of prospects into mines, and hence, inevitably, a dying and then a dead mineral industry. Without the discriminating judgment advocated by Mr. Campbell, our engineers and investors would soon dissipate their tangible resources in attempting the impossible.

It is obvious that there is required a judicious combination of optimism and caution if we are to effect a rapid and sound development of our mineral resources. Seldom are these qualities combined in one man; hence co-operation is necessary among those possessed of these opposing inclinations. Men with the calculating caution that Mr. Campbell upholds must ally themselves with others having the enthusiastic temperament that impels them to the vital work of exploration and research.

It is impossible to prove or disprove the actual dimensions of Canada's future mineral industry and of her present latent possibilities; only the prospector and engineer of this and future generations can do that. Meantime we must provide for the use of the prospector and the engineer adequate means for their purpose, so far as is consistent with sound business management. By directing wisely the maximum of effort available, we shall make the most of what we have—and no one can do more than that. Mr. Campbell has provided a very useful contribution to this end.

HOW MUCH MONEY WILL THE SWINDLERS MAKE?

The "Golden Opportunities" are coming thick and fast, according to prediction. They are genuine opportunities—to the promoters of fake mines and bogus stock. The advertisements must be bringing a handsome income to the newspapers. Even the most cautious and conservative of our dailies has succombed to the lure of the full-page "ad." It is "in the swim", now, with all the rest of the daily press. It is very difficult to refuse advertising from any source, and it is almost impossible for any but those well versed in mining matters to discriminate between genuine and illicit mining stock promotions.

The *Canadian Mining Journal* accepts no advertisements of mine promotions. Adherence to this principle has put us under the painful necessity of refusing a lucrative source of income. We are confident that the facilities available allow us to distinguish sufficiently clearly between genuine and counterfeit; but we are determined to be under no suspicion of subsidy, whatever the cost. Our

hand is completely free to commend or to condemn, without fear or favour.

There has been, recently, only one gold mining stock offered to the public that we are prepared to recommend, without qualification, to the man who can afford a legitimate and promising speculative investment. There are a small number of stock flotations based upon mining properties that are of sufficient promise to warrant the expense of development; but we are not fully satisfied that the money obtained from the public has been expended wisely in all cases. We have refrained from adverse comment on these stock flotations; with good luck, they will pull through and may make a reasonable or even a handsome return on the investment.

There are a host of illicit stock flotations, based mostly upon mining claims that are not of sufficient promise to attract the genuine operator or mining investor. Some of them are in close proximity to producing mines—but that proves nothing in itself. Some are far removed from any productive area, and pretend to be close. All claim to have important geological and structural features in common with Ontario's famous gold mines; few of them have anything of the sort.

Even to enumerate these bogus stock flotations would take more space than we care to give them. They are multiplying daily, and each seems to be more of a barefaced swindle than the last. The circulars and the bogus mining periodicals got up for the occasion, as well as the strenuous campaign of newspaper advertising, are bound to separate some careless or credulous persons from their loose change. It is impossible to protect the fool from the swindler. We hope that few with ordinary common sense will be deceived by propaganda now being conducted by numerous members of the light fingered profession.

EDITORIAL NOTES

At least one part of the British Empire recognizes publicly and officially the prime importance of its mining industry. The South African Minister for Mines and Industries (note the significant conjunction of responsibilities) has recently issued his annual report for 1921. He mentions that the gold mines are working almost normally and the reorganization effected has reduced working costs in such a way as to enable the low grade mines "to carry on." He adds that still more efficient operation is essential to ensure the continuance of gold mining, the most important of South Africa's industries. The white miners, who were formerly not only autocratic but inordinately self seeking, have now commenced to work for a living. Apparently their habits of application are not yet sufficiently developed to meet the needs of the case.

On October 13th we stated, on page 687, in discussing "Institute Membership", that "the mining engineers of "Ontario have, at their own request, been excluded from "the provisions of the Professional Engineers Act of "Ontario." Mr. R. B. Wolsey, secretary of the Association of Professional Engineers of Ontario, has drawn our attention to the fact that this statement is decidedly in error. Mining engineers are included with others in the provisions of the Act. The misapprehension, which is not confined to the editor of the *Journal*, is probably due to a copy of the bill that was circulated last year, containing such an exemption, the bill as then drafted requiring all engineers practising in Ontario to join the Association. As passed by the Legislature, the Act incorporates a voluntary Association, there being no legal compulsion for practising engineers to join it. Thus the exclusion of mining engineers from its provisions, deemed necessary in the first instance, is not required in the bill as finally passed.

Coke of a dense variety is the best known substitute for anthracite coal for domestic use. It is with a view to making this excellent domestic fuel as a by-product that such a determined effort is being made to discover an economically feasible method of low-temperature carbonization. Meantime, the ordinary by-product process of making coke at a high temperature provides a first-rate fuel after saving part of the valuable volatile constituents. It may be feasible, even without any new invention, to bring bituminous coal westward from Nova Scotia and eastward from Alberta to large centres of population and there resolve it into its constituents, solid, liquid and gaseous, all of which can be used to advantage locally. This is one of the tentative proposals of the newly created Fuel Committee in Ottawa of which Dr. Charles Camsell is chairman. Mr. Moffatt's article in this issue on the manufacture of coke in Nova Scotia is timely.

The Financial Post of Toronto published last week a special supplement featuring Canada's mining industry. The consistent optimism, and even exuberance, of the special articles that compose this excellent resume of our mineral industry, present and future, is tempered by a most decided warning against the dangers of the indiscriminate buying of mining stock. *The Financial Post* is rendering the investing public a notable service in exposing undoubted fraud wherever it is found, whether in illicit mining stock promotions or in similar shady means of collecting cash from the gullible or the unwary.

The slide of rock in the pit of the Asbestos Mines, Limited, East Broughton, Quebec, last week, that killed four miners is one of those unfortunate accidents that cannot be foreseen nor provided against. The local management and Mr. Jacobs, at the headquarters office in Montreal, spared no pains or expense while there was still a faint hope that the huge blocks of rock might have lodged around rather than on, the entombed men. Here there is demonstrated, once more, the fact that human life is held above money in a well-ordered mine, as in any other part of our modern civilized life that rises above mere savagery.

Statistics and the Canadian Mining Industry

A LETTER FROM MR. C. M. CAMPBELL, GIVING STATISTICS AS TO CANADA'S MINERAL INDUSTRY

To the Editor,

Canadian Mining Journal.

Some months ago I wrote a letter to this journal protesting against what I considered extravagant language used in an editorial. This was the subject of some criticism, favorable and otherwise. About the same time Dr. Corless, as President of the Institute, made the public statement that mining would be "Canada's greatest industry of the future" and it was a "fact" that we "had inconceivable wealth in minerals." I therefore protested again as strongly as possible. This correspondence was the subject of an editorial by yourself and an article by your special contributor, Mr. Alexander Gray. The matter has been further discussed in the Bulletin of the Institute.

In investigating this subject I have tabulated a large amount of statistical information for my own guidance. I propose to submit some of these tables as I believe that the information they contain is of sufficient importance to well warrant this publicity.

It has been stated that anything can be proven by statistics and that there are lies, damned lies and statistics. Those submitted I believe to be correct and you and your readers can judge whether or not I have drawn any unwarranted conclusions therefrom.

Annual Production

The annual mineral production is, generally speaking, an indication of the mineral wealth of a nation. The following table indicates the relative importance of the mining industry in Canada and in some other areas on this continent.

	Mineral Production 1918	Pop.	Per Cap.
Pennsylvania	$979,245,098	8,720,017	$111
Oklahoma	336,857,921	2,028,283	166
W. Virginia	327,962,620	1,463,701	225
Illinois	271,244,365	6,485,280	41
Ohio	246,162,215	5,759,394	43
California	204,673,547	3,420,861	60
Arizona	203,992,915	334,161	614
Canada	211,301,897	8,788,483	24
United States	5,540,496,000	105,710,620	52

I have taken the year 1918 as it is the latest year for which the U. S. Geological Survey have published detailed statistics. It was also a year when production in all cases was at a maximum. The fact that the populations shewn are for 1920 and 1921 means that the per capita figures are only approximately correct. Relatively speaking they are very nearly correct.

From the above it will be seen that certain states that have not been popularly considered as mineral producers have a much greater per capita production than Canada, while an area like Arizona is not approached by any other state or province. I would not like to say that it is not possible for a province like British Columbia to have great undiscovered mineral deposits; but a trip through the coastal jungles of British Columbia will convince anyone that if mineral wealth is there it is likely to stay there except in the few cases where outcrops indicate the possibility of encouraging results. Though they might greatly increase our mineral wealth, British Columbians do not desire Arizona conditions. There are compensating advantages.

The next table compares the value of the mineral production of Canada with that of some other Canadian industries. The figures are also for 1918.

Dairy products	$256,000,000
Forestry	209,528,000
Goods manufactured in Hamilton	193,638,000
Mineral Production of Canada	211,301,897
Goods manufactured in Ontario	1,809,067,001

The above table shows that the production of one of the minor divisions of our agricultural industry is greater in value than the entire mineral production, that the forest production and the manufacturers of a city like Hamilton about equal it. In the case of manufactures, to avoid duplication, all statistics include a special column for cost of materials. In the manufacturing industry this is usually the greatest item. In the mining industry it is an appreciable item though seldom referred to. The millions of tons of Canadian coke that has been used in our smelters appears in our records as coke and also as part of the value of the smelter products produced. In the case of Hamilton the comparison is not an unfair one as the value of Canadian mineral products that entered the finished product was probably less than the value of the non-mineral supplies that went into the mineral output.

I have also included in the above table the total value of the goods manufactured in Ontario. An examination of the mineral production of that province shews that the proportion that appears in the total value of the manufactures is a small one. Ontario is a great manufacturing province and for its manufactures of metallic goods thanks are due mainly to raw mineral products from the neighboring states.

Mineral Imports

Mineral Statistics in Canada are confined to tables of production. This seems to me to give a one-sided idea of the situation and I have therefore compiled the following table shewing the imports of mineral products for 1921 as furnished by the Canada Year Book:

METALLIC		
Iron: Ore	$ 5,995,038	
Rolling Mills products	75,604,655	
Smelter products	4,583,053	
		$ 86,186,746
Aluminum:—Alumina	1,675,020	
Ingots, blocks, etc	566,944	
		2,241,964
Brass:—Bars, rods and coils	478,634	
Scrap	663,468	
Strips and sheets	376,350	
Tubing	366,884	
Woven wire	489,788	
		2,375,124
Copper:—Bars and rods	5,724,064	
Blocks, pig and ingots	1,396,327	
Strips, sheets & plates	586,399	
Tubing	319,536	
		8,026,326
Lead: Scrap, pigs and blocks		1,971,392
German, Nevada and Nickel Silver		526,741
Precious Metals		2,753,571
Tin and Products		2,962,644
Zinc and Products		584,474
Ores and metals n. o. p.		176,989

NON METALLIC	
Bricks, etc.	3,021,600
Coal	111,298,100
Coke	6,247,931
Glass and products	11,083,028
Petroleum and products	51,438,351
Stone and products	4,836,784
Diamonds (uncut)	2,384,150
Salt	1,372,199
Sulphur, crude	1,729,808
Fertilizers	4,272,054
Inorganic Chemicals	7,4 0,430
	$312,890,406

The above figures are for the fiscal year and should be compared with a mineral production of about $200,000,000 for the same period. Appreciable reductions should be made as the records do not in all cases exclude manufactured articles. However, after every allowance is considered I think it will be admitted that our total mineral production is less than our imports. The fact that we may have control of the nickel and asbestos situation and that the production of gold is increasing is seriously discounted when we study the list of minerals we are short of. The table also indicates that some of our industries are, to use the language of the photographer, being "developed" but not being "fixed". For example, among the metals we ship out our copper, lead and zinc in large quantity and then pay about as much to get part of it back again as we received for all that we exported. The introduction of refineries is a forward move, though the table indicates that there is room for much further endeavor.

Comparison with Other Industries

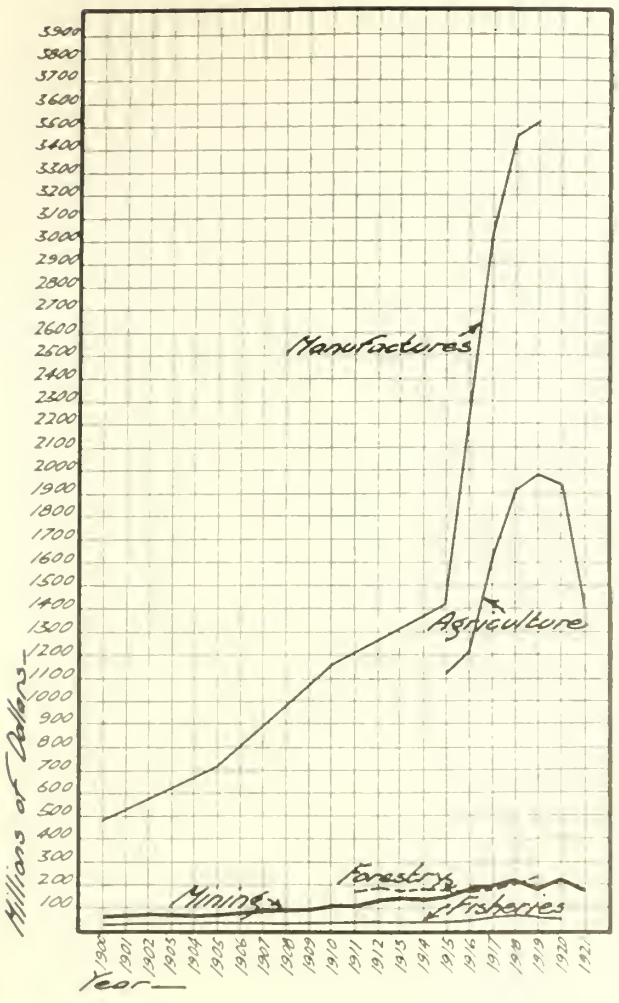
A comparison of the mineral industry with that of other industries for the last 20 years is shewn below in graphic form. The curves are not complete but are as complete as statistics supplied from Ottawa will permit. They shew mining production to occupy a place appreciably above fisheries but slightly below the forest production. Far above are the products of manufacture and agriculture. Canadian mining engineers have not been backward in declaring that the mining industry is forordained to soar in the upper ether. It would seem that the start of this meteoric flight is somewhat overdue.

Coal Statistics

Coal statistics have recently been brought into prominence by Dr. Corless' statement that we have 1,234 billion tons and his announcement that this would be good for 35,000 years, at the present rate of consumption, was telegraphed to all the daily papers and in many cases appeared in heavy type on the front pages. Dr. Corless is lauded in your journal as an "Optimistic Engineer", and men who make statements of this class as "Conrageous Leaders".

The above tonnage estimate was obtained from Vol. 2 of "The Coal Resources of the World", prepared by the Geological Survey of Canada. I am entirely at a loss to know how any mining engineer can arrive at Dr. Corless' estimate of 35,000 years after a study of the details as set out by the survey.

In the first place, 1,073 billions tons, or 7 tons out of every 8, is located in Alberta and the fact that the great bulk of our reserves is located in an area inaccessible, on account of freight rates, to the great majority of Canadians is a detail that should be emphasized when any statement is made in regard to our reserves. This is especially the case as other countries, with which we make comparisons, often not only have better coal but have it



better distributed. In the second place, 948 billion tons, or over 3 tons out of every 4, is lignite or similar low grade material that will not warrant transportation charges except for very short distance. Even if the heavy expenditures that are being made to devise some method of improving and briqueting this material result in success it can only be done at the expense of a heavy loss in the original tonnage figures. In the third place it is very essential to note that only 115 billion tons, or 1 ton in every 3 is "actual" coal, the balance being "probable" coal. This balance contains such items as a probable 17 billion tons, 2 ft. thick, located at a depth of from 4,000 ft. to 6,000 ft. In the fourth place, even this "actual" coal, as the record states, "includes seams 1 ft. thick to a depth of 4,000 ft." On Vancouver Island, unless the coal is extra good, it is not worked when it is under 3 ft. in thickness, even near the surface. At the other extreme are mines where the coal is too thick, such as one of the big mines at Coal Creek where only 10 ft. of a 40 ft. seam is worked. United States figures are based on coal 14 inches thick to a depth not exceeding 3,000 ft. The United States total of 3,225 billion tons specifically excludes 604 billion tons between 3,000 ft. and 6,000 ft. Due to the hallucination of the public that it is being robbed by the coal companies a state of mind brought about by extravagant statements in regard to our coal deposits—the competition of the coal companies with each other and the competition of all of them with the fuel oil industry, the price of coal is at such a level that only the best and most easily mined can be taken and the loss in recovery is simply enormous.

I have been accused of being a pessimist; of holding a "lugubrious brief"; of "attempting to belittle the mining

industry and of being lacking when it came to a question of intelligence. These remarks have been made in different journals and represent the penalty one pays for taking the negative side in a popular belief. My chief crime seems to be that I have insisted that engineering rules which apply to individual mines should also apply when statements of "fact" in regard to our national reserves are being made and when the life of these reserves is being estimated. No reputable company, it is generally admitted, in developing its property will estimate its life mainly on probable reserves; it will not ignore loss in recovery and it will not, if it be a coal company, seriously consider seams 1 ft. thick at a depth of 4,000 ft. National reserves, I am convinced, should be treated in the same way.

Possibly at some future date some means will be devised whereby thin seams will be worked, lignites improved so as to approximate anthracite and the present loss in recovery eliminated. However, until that day arrives this extra tonnage should not be used as a factor in estimating the life of our coal deposits. In addition to this I also think that our Geological Survey should seriously consider a revision of their figures downward and that public attention should be drawn more to the necessity of conservation even in coal.

The Mining Industry and the Railways

An entirely exaggerated idea of the importance of the mining industry in its relation to the railways is prevalent among American and Canadian mining men. The publications of the United States Bureau of Mines, even those that do not even remotely deal with railway statistics, contain tonnage tables designed to shew "the magnitude of the mining industry as a contributor to the revenue-producing freight carried by the American railways." These tables shew only half the truth and while it is very important that the effect of the mining freight should not be underestimated, it is just as important that it should not be overestimated. The deduction naturally made—that the importance of an industry to the railways can be approximately gauged by the proportion its freight tonnage bears to the total tonnage carried—is very wide of the mark.

The statistics in question, as far as Canada is concerned, are summarized in the latest Canada Year Book and tabulated for 1920 as follows:—

	Tons	
Products of Agriculture	23,304,979	18.3%
Products of Animals	3,801,130	3.0
Products of Mines	45,075,968	35.4
Products of Forests	22,278,880	17.5
Manufactures and miscellaneous	32,925,394	25.8
	127,429,154	100.

In justice to agriculture, the entire tonnage of animal produce should be credited to it, making that percentage 21.3 per cent. Unless one is familiar with actual conditions, he will assume that all this tonnage originated in Canada. As a matter of fact, 34,954,469 tons was obtained from United States roads and a further 27,379,108 tons was received from other roads in Canada. Restricting ourselves to Canadian tonnage and allowing for no duplication, the total can therefore be cut in half. Of the tonnage originating in the United States well over half, or close to 20,000,000 tons, represented mineral tonnage in the shape of coal imports to which the Canadian mining industry can lay no claim whatever. The tonnage supplied by the Canadian mining industry will therefore be seen to be a completely different figure.

In a paper by Dr. Camsell at the last meeting of the Institute he said, "Possibly if the figures were given in ton-miles the percentage of the other groups might rise at the expense of the mine products." In following up this lead and in taking into consideration the different rates on different articles I find that the percentage of other groups rises to such an extent as to demand an altogether different conclusion than the one prevailing, as to the supreme importance of the mining industry to the railways.

As the table now stands it puts a transcontinental silk train—and the silk traffic is an important one, for our Empress boats have brought in silk cargoes valued as high as $8,500,000—on the same basis as a train of gravel from a suburban pit into a city. It makes no difference whatever between 4 times 1st class, and 10th class rates. The table includes some very heavy tonnages on short hauls, such as 1,882,774 tons hauled by the Algoma Eastern consisting mainly of raw ore, coke and flux for the Copper Cliff Smelter and 3,484,094 tons, almost entirely coal, handled by the Sydney and Louisburg Railway which has a total length of only 69 miles. Tonnages such as these should really be deducted, as railways of this type are often operated by the mining companies as part of their own equipment. Examples are the roads operated by the Granby Company at Anyox and the Canadian Collieries on Vancouver Island.

An examination into the details of the mining tonnage as given in the following table shews that the items are mainly of that bulky class which takes about 10th class rates and which are characterized by a short haul:

	Tons.
Coal and coke	33,796,034
Iron Ore	899,546
Other ores and concentrates	2,127,184
Base bullion and matte	173,851
Clay, gravel, sand, crushed stone	4,473,155
Slate, dimension or block stone	1,216,140
Crude petroleum	1,051,006
Asphaltum	248,672
Salt	307,135
Other mine products	782,245
	45,075,968

All railways do not prepare their statistics on a ton-mile basis or segregate their revenues. A table of this nature for all Canada is therefore not possible. The following table for 1921 based on these figures, from the point of view of the Canadian Pacific is, however, submitted. As this is an outstanding railway covering all parts of Canada this table represents, I think, a more accurate idea of the relative importance of the different industries to the railway:

Class	Tons.	%	Ton-Miles	%	Revenue	%
Agriculture and animals	11,310,372	38.5	5,473,863,186	51.	$46,258,805.01	36.2
Mines	3,686,840	12.6	742,287,120	6.9	6,646,898.41	5.2
Forests	2,432,491	8.3	1,165,319,850	10.8	10,824,168.01	8.6
Manufactures and other products	11,893,457	40.6	3,359,459,766	31.3	63,952,599.78	50.0
Total	29,325,160	100.	10,740,929,922	100.	$127,682,471.21	100.

Those who followed the recent freight inquiry will also remember that the statement was often made by railway officials that the carrying of low grade commodities resulted in actual loss. I do not know what this loss amounts to and do not think it is serious, but am prepared to believe that in the case of much of the mineral freight carried the profit is very small. In other words the mines may even produce a smaller proportion of net profit than the revenue percentage would indicate. On the other hand some semi-manufactured products now classed as manufactures might legitimately be classed with the mine products. Agriculture and forest figures would also be raised for the same reason. Iron products, however, could hardly qualify, as our production of iron ore is negligible. Even making a liberal allowance for these additions and the possibility that the Canadian Pacific table may not quite represent the railways as a whole it is obvious that the Canadian mining industry occupies an interior position far below the keystone location that the tonnage table would indicate. That its position can be improved, I have no doubt, and the endeavors of the Geological Survey along this line will be watched with interest and approval.

Prophecies

An editorial which was published in the issue of June 9th, indicates that you are under the impression that Dr. Corless' statement was in the nature of a prophecy. Mr. Gray seems to be of the same opinion, for in discussing the situation about the same time he claims the matter "is incapable of general solution until a few decades have elapsed and more work is done." Dr. Corless' statement was a statement of 'fact' and not a prophecy and as such there is no occasion for any delay in estimating its accuracy. If it is a "fact" that our mineral wealth is "so great that it cannot be conceived or imaged by the mind" the truth of the matter should be so apparent as not to call for any intensive program to prove it.

Many prophecies have been made in regard to our mineral wealth. They are usually elusive, as the prophets seldom include a time limit for their fulfilment. The following parallel, however, shows how one prophecy went astray.

[illegible]

[illegible] Canadian Mining Journal, April 15th, 1911.

[illegible]

I do not know what Canadian mining engineers told Dr. Hewett that made him publish the ridiculous prophecy attributed to him. The information supplied, however, was much in line with that which was being supplied elsewhere and at the same time by other Canadians to outsiders who invested in rock exposures under the impression they were buying fruit lands. As far as I know the prophecy was not contradicted and it appeared in the Canadian Annual Review for 1905 as one of the outstanding development incidents of that year. It had its share in bringing about the boom conditions that lasted till about 1912 and from which we are likely to suffer for many years.

Other statistics on propheeies include the sayings: "Never prophesy unless you know" and, "Prophecy is the most gratuitous form of error."

Sporting Spirit vs. Engineering

Before closing I wish to draw attention to another remark of Mr. Gray's that should not pass unchallenged, for similar remarks are still being made. It is his concluding sentence in the article referred to. He says, "Sporting spirit is what makes the world move". This may be all right for a sporting magazine, but for an engineering journal I would suggest that, if it is to be used as a rule, the word "backward" be added. Much the same advice is given by Mr. G. R. Mickle when he concludes his letter in the current *Bulletin* with the sentence, "Let us take a chance."

About 10 years ago the people of British Columbia, then worshipping the false gods, Inconceivable Wealth and Sporting Chance, embarked on the construction of the Pacific Great Eastern Railway, projected so as to penetrate the heart of the province. This railway has cost the province over $10,000,000 to date. Railway experts of national reputation have gone into the situation in detail and now find that there is no prospect that traffic can be created as a result of development, and this includes mining development, for many years to come. They also find that unless the people are prepared to continue paying from $2,000,000 to $2,500,000 yearly the proposition should be abandoned in whole or in part.

The raising of this money by increased taxation and by cutting down expenditures has meant a heavy handicap to this province. Income taxes have been put on much the same basis as those of the Dominion; the poll tax has been resurrected and every other form of tax exploited; mining companies complain of unfair and retroactive taxation and other industries denounce taxes as having increased by leaps and bounds. All the Government departments are suffering from lack of funds. Schools now built are of a cheaper type or not built at all and the University has to conduct classes in tents. Provincial roads are dangerous in places. Mining investigations which were formerly made at the expense of the Government have now to be made by the companies or not made at all. There is no attempt at reforestation and the debris from logging is not cleared up. Last summer there were 2250 forest fires. Lives have been lost and, though fortunately there have been no tragedies such as those in Northern Ontario, there is no assurance that these may not occur. For three months during the past season it was impossible to see across the Straits of Georgia and at times the smoke was so dense that vessels had to use their foghorns. There is now only one stand of virgin timber along the highway between Victoria and Alberni and a trip through this is an experience to be remembered. The Government cannot afford to preserve this, has said so, and we can only prepare to contemplate a desert of blackened stumps and fireweed. In California they plant trees by the side of their highways and preserve their beauty spots. In British Columbia we are in such a position that [illegible] to pay interest on our gambling debts.

"We will muddle through in true British style," said Premier Oliver. The number of individuals and corpora-

tions, however, that didn't "muddle through" when the boom burst is legion, and it is not uncommon these days to read of municipalities that are bankrupt. Even if the P. G. E. is abandoned the salvage is limited and there will always be a heavy interest charge. Another sporting move like this project and the province may be sold out at a sheriff's sale.

The present generation in B. C. came into a wonderful heritage. An appreciable part of it has been destroyed and we are handing it down not only seriously impaired but with an additional heritage of heavy debt. I cannot see anything sportsmanlike in this. I am prepared to pay my share and more than my share to help clean things up but I do not propose to stand idly by while leaders in the mining engineering profession continue to publish statements that are not only unjustifiable from an engineering standpoint but also have a tendency to tempt governments and communities to make further extravagant expenditures.

Yours, etc.

C. M. CAMPBELL.

Cassidy, B. C.

The Manufacture of Coke

BY-PRODUCTS PLANT AT SYDNEY

By JOHN MOFFATT

The By Product Department of the Sydney Steel Plant is most interesting, especially to the layman who in his own way has learned of the many things, besides heat, that can be extracted from coal.

A Scene of Order

The first impression one receives on looking over these extensive works is the simplicity of the arrangement, of its large buildings and railway tracks, the order and taste with which everything is laid out, the safe and sanitary conditions under which men work, the clock-like precision with which all work is done, and the ingenious machinery used in doing much of it, as well as the marvellous results obtained within a few hours by undoing what it has taken nature many thousands of years to do. The level yards with their many covered-in pipe lines and their whitewashed curbs or brick arches just high enough above the surface to afford a clean footpath (if that were at all necessary where the ground looks as if it had been newly rolled), and the dolomite walks of other more defined and permanent pathways, all add to the comfort and convenience of getting round; and if one adds to this the pleasure of listening for the first time to a highly intelligent workman explaining the different processes by which coal is made to give up its varied stores of wealth, the attention and interest are held spellbound while he passes from one phase of the work to another. Here and there on the way round, sheltering behind high buildings or adorning the centre of a well-trimmed lawn, are beautiful little flower gardens, all tending to give a feeling of the aesthetic and of repose in the center of this hive of industry. It is good that it is so. It was Darwin who said that the pursuit of scientific study over a long life lost him the capacity to see the beauty of a flower.

Here where scientific minds, with all the ardor of their profession, spurred on by the fierce conflict of commercialism, are liable to be robbed of the taste for the beautiful things in life, it is well that the eye should be arrested by the artistic and the fragrant flowers that "toil not neither do they spin."

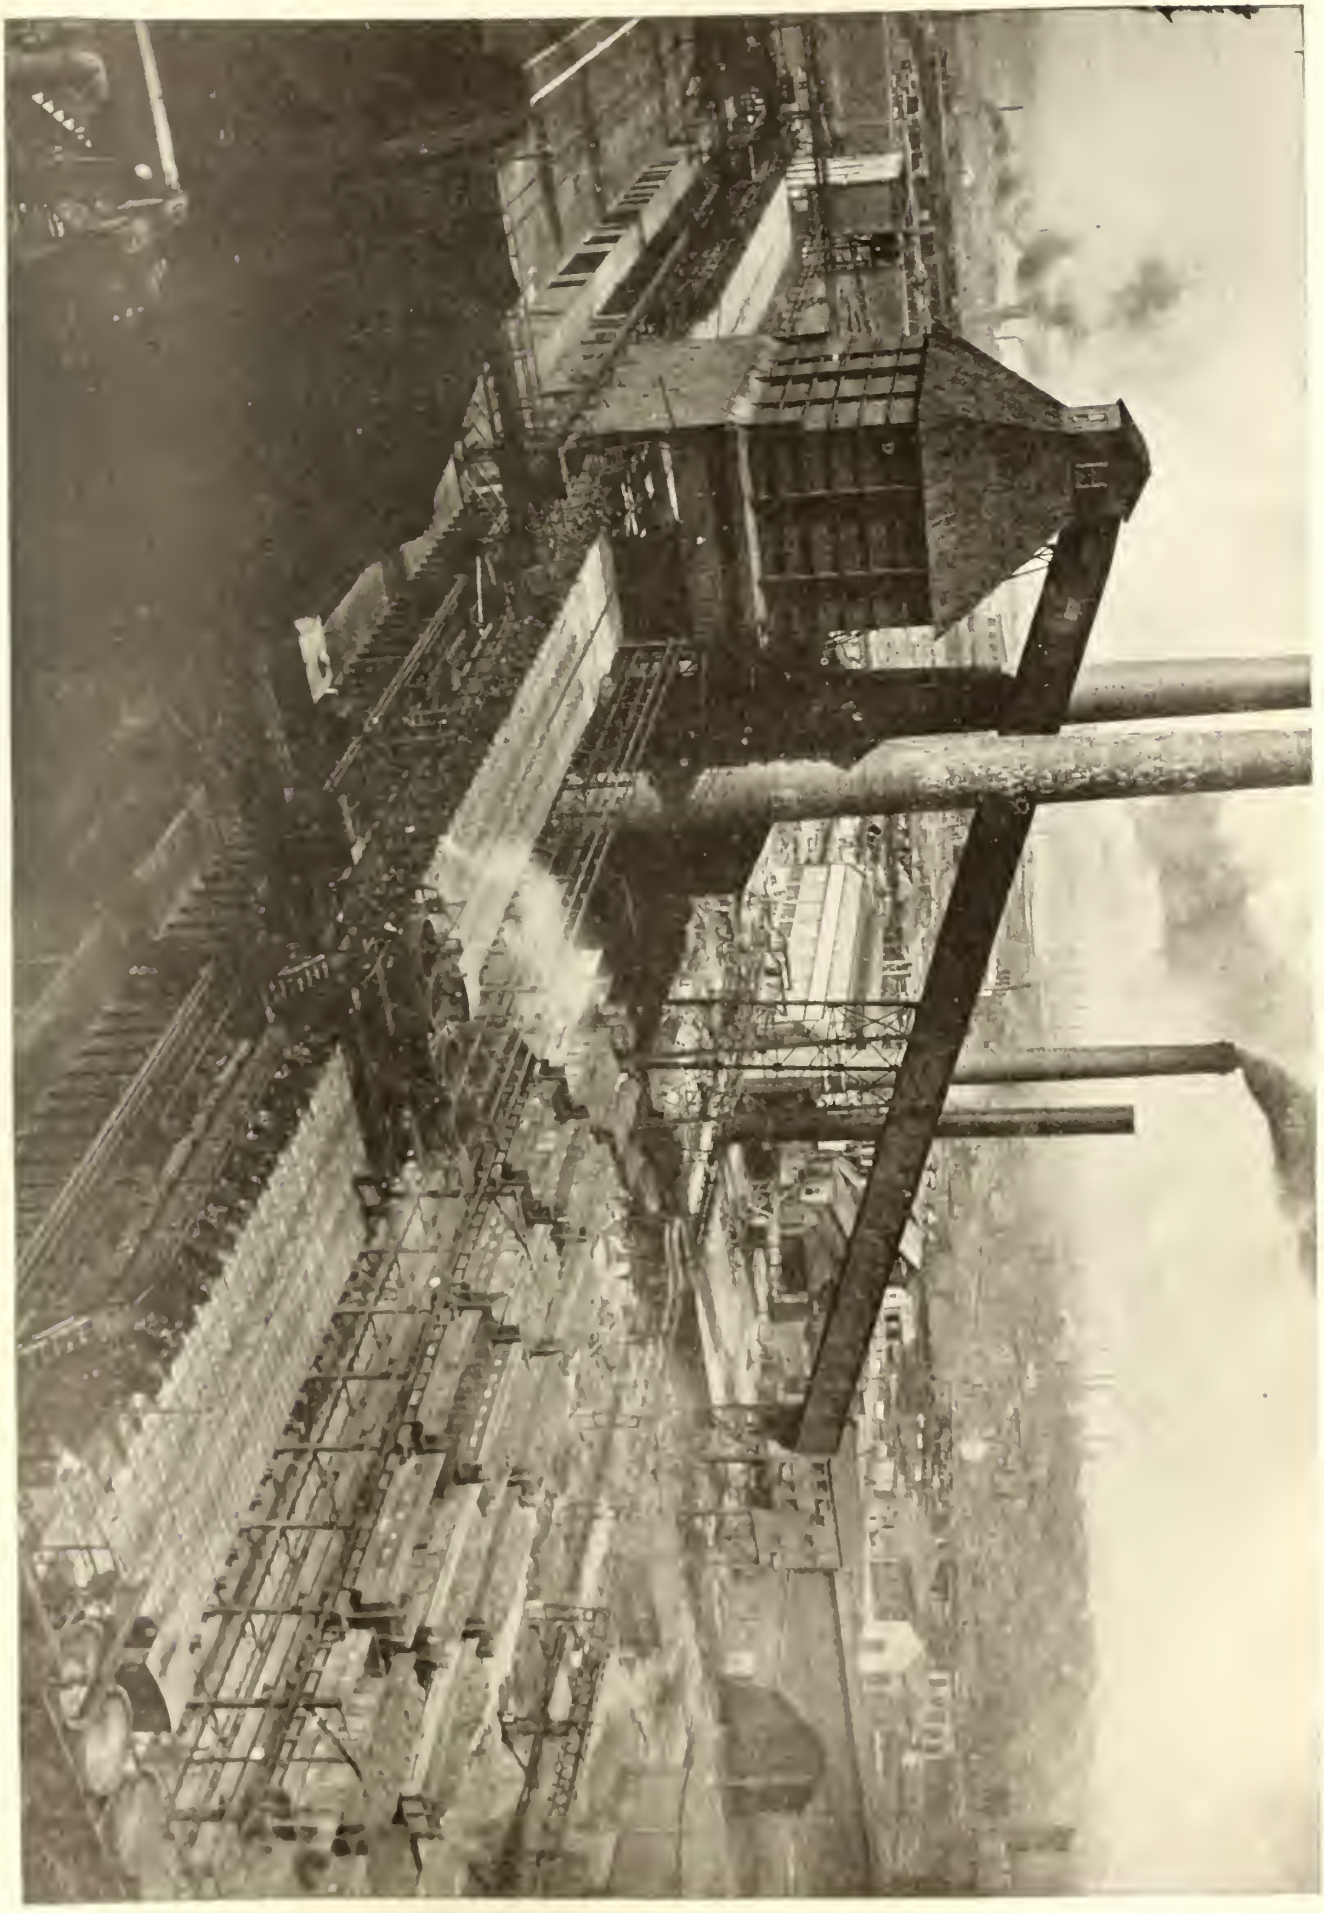
The Coke Ovens

The Dominion Iron and Steel Company has never been very prodigal in the use of coal. Only for a short time at the beginning were Bee Hive coke ovens used. "In 1900 five hundred ovens of the Otto Hoffman type were built. These had a coking period of 48 hours and a daily capacity of 1,000 tons, and when the plant was in full operation 400 men were employed. But twenty-two years works many changes and sees old methods of doing things dropped and old machinery scrapped. The Dominion Steel Company, to keep abreast of the times, have within that period twice changed their coking plant, improving it each time, so that two batteries of 60 ovens each now produce 1,200 tons of coke per day. The ovens are larger, but with the improvements in construction and heating, coke is turned out in eighteen hours, as against forty-eight in 1900. With dry coal the time period of the new ovens is sixteen and one half hours. The wet slack as it comes from the washer carries eleven per cent. moisture and requires a higher temperature and a longer time to dry this off and make coke. The increased output is made with 200 men, or a reduction in force of 200 men per day. This is surely economy of the highest order and points to tremendous progress in the making and handling of coke. To revolutionise a plant of this size costs money; but it pays and it is only by keeping in the forefront that trade can be obtained and profits made.

A complete description of this plant was given some time ago in *"Iron and Steel of Canada"* by Superintendent C. E. Wallen, an English gentleman, educated in Oxford, who followed up his chemistry studies in Vickers Works and in the Sydney Steel Works after coming to Cape Breton. He is thoroughly qualified and capable and fills his position with ability and success. I will not therefore attempt the impossible (to me) and try to repeat the description.

Separate Quenching Area

A noticeable feature of the change wrought through the introduction of machinery, is that in respect to labour, especially that part of it that has to do with the work of making coke. Five hundred coke ovens had, at the beginning, to be discharged by hand and cooled by hose at the place of discharge. It was hot, dirty, disagreeable and tedious work and required a large number of men. In striking contrast today is the speed with which this work is done and the ovens relieved of their charge, the whole being forcibly pushed out in a few minutes by machinery into a wide dumping car of steel and cast-iron construction. The car is then removed by an electric locomotive to the quenching station where the coke is subjected to a spray of water for 35 to 40 seconds. After draining in the car for five minutes it is discharged to the coke wharf. No change could be more complete, and the absence of smoke in the rapid cooling has taken away the standing reproach of the coke oven department, which because of its stifling fumes and its smoky, murky atmosphere is iso-



BY-PRODUCT COKE OVENS AT SYDNEY, NOVA SCOTIA.

hated, far away from the homes of men and placed outside the pale of civilization. This leprous blight has all been removed, and the cooling having been relieved of its fiery and poisonous breath and its smoke screens, the coke department may now be freely admitted to the company of other respectable and less despised parts of the main works.

Coke Used Immediately

Coke is not stored, and the work of the ovens is timed to meet the requirements of the furnaces and foundries. This requires nice manipulation and a thorough knowledge of the quantity wanted. But when one looks at the time clocks and charts, by which the making of coke is regulated, the heat being changed from one side or other of the oven every half hour, one can easily understand how coke can be delivered at any specified hour.

Coke, like coal, must be screened to remove the fine sizes. The quality of the coke is good and the supply of metallurgical coal so far as known may be only limited by the distance to which undersea mining can be successfully carried on.

The recent activity at the Steel Plant and the putting into operation of a second blast furnace almost doubled the quantity of coke used, and if trade should continue to improve further and the third blast furnace be blown in, all three batteries of improved type would be required. Many of the older ovens have been repaired and if wartime activity should again return the coke supply will be equal to the demand. As it is, more could be done by the present ovens; but as the method of doing it might be a trade secret we shall pass it over.

The By-Products

In reply to a question asked, if the ammonia fumes were not injurious to health, the answer was that they are not known to be and that such small quantities escape into the atmosphere that no workman has been known to be affected by them. No complaint was ever heard, but to the contrary a little ammonia in the air is held to be a disinfectant. Working with tar is known to be wholesome so long as plenty of fresh air is admitted to the buildings, or the work done in the open, as is the case here.

Sulphate of ammonia, tar, benzol and gas, are the chief by-products. The recovery made under the improved conditions are tar, 11 gals. per ton coal, as against 7½ gals in the old ovens, sulphate of ammonia per ton coal, 18 to 28½ pounds; surplus gas, 3000 to 6400 cu. ft.

After the volatile matter has been distilled from the coal, the tar is extracted and the gas treated by various processes until in turn all the products desired are obtained.

The increased yield of by-products from coal in ovens of recent design is largely due to developments that have taken place in the last ten years. The oven construction itself is of a more solid nature, the temperature of carbonisation is more accurately controlled, and the pressure and temperature of the gas generated are, during the various phases of its subsequent treatment, regarded as a matter of the highest importance. To such an extent is this the case that in the plant under notice some forty automatic regulators and temperature and pressure recorders are in operation. The result is that not only is more uniform operation obtained, but the workmen have a readily visible indication should anything abnormal occur. In addition, each part of the operation is the subject of constant chemical control.

The Market for By-Products

Sulphate of ammonia is in great demand in the West Indies on the sugar plantations. The Tar and Chemical Co., Sydney, use up all the tar, and here other by-products are extracted. These are creosote of several kinds, cement roofing, and disinfectants. Pitch, being the residue of tar, is exported in large quantities. Napthalene and other light and heavy oils were for a time included in the by-products of tar, but for the present some of these are not extracted and are allowed to remain in the pitch.

Benzol sprang into favor as a motor fuel and is preferred to gasolene. Unfortunately the storage capacity of the plant is limited and the supply this year was used up within a few months. There was general lamentation among autoists when it became known that benzol was almost off the market. There should, however, be some way of storing a larger supply and saving the benzol, for if it cannot be safely and economically stored, it is not extracted and is lost as a by-product. The use of the motor car, in a climate like Cape Breton, is only seasonal, and the full output of at least four or five months would have to be stored, for auto driving after October is seldom done for pleasure. The matter is under consideration and in due time the case will be met.

Other by-products extracted during the war were toluol, xylol, and solvent naptha of the highest degree of purity and in great quantities. Not the least cause for pride among Nova Scotians was the fact that the industries of the Province could be made to play a great part in the world struggle for the right, and foremost among these industries was the great Dominion Steel Works at Sydney.

GOLD REPORTED IN NEW BRUNSWICK

Press despatches record two discoveries of gold in New Brunswiek, one near Shippegan in the northeast corner of the province and the other in Carleton County, near the Maine boundary. Prospectors licenses have been take out in both cases. Mining is very backward in the Province of New Brunswick and there has been very little prospecting done throughout the interior, though a large part of it is readily accessible by railway and has rocks of such geological character as make mineral occurrences possible. A genuine gold find of workable dimensions would, doubtless, attract prospectors from other parts of Canada and would stimulate a thorough search through this long neglected part of Canada.

Preliminary returns to the United States Geological Survey on coal production in the fourth week of October indicate a total of 12,500,000 net tons, of which about 10,400,000 tons is bituminous coal and 2,100,000 is anthracite. Revised estimates for the third week show 10,365,000 tons of bituminous and 2,003,000 tons of anthracite. A slight increase in the total coal raised is thus shown for the present week as compared with the week before, which increase is practically entirely in the output of anthracite. The gain in the rate of production during the past two weeks reflects some improvement in the transportation situation which, however, remains the principal factor limiting output. The rate of output is approaching adequacy but does not yet assure sufficient coal to meet current needs, the required movement up the Lakes, and to provide the desired consumers stocks.

News and Comments

BY ALEXANDER GRAY

The Gaspe Zinc Lead Impasse

Gen. Charles A. Smartt has asked the Quebec Government for all the correspondence bearing upon the endeavors of the Federal Zinc & Lead Company to obtain assistance in the construction of a road suitable for tractors, to connect with its Gaspé mines, of conceded importance. Whether or not relief will be accorded as a result of the Smartt inquiry, is not for discussion here. That the zinc-lead deposits developed and capable of further great development, are of exceptional merit, no longer is in dispute. Prominent engineers representing rival concerns of Canada and the United States pronounce the Gaspé occurrences to be unusually strong. The country in general has all the attributes essential to mineral discoveries, so the Federal Company has not the only bird in the bush. It is not strictly equitable to compel the Federal Company to build an expensive highway when the whole section will be benefitted. Besides, there is a market for zinc and lead. The further cost involved in the completion of the road would be trifling compared with the momentum the expenditure would give to the development of the peninsula. The equities, if not the exigencies, suggest co-operation on the part of the Quebec Government. Called for zinc and lead in quality and quantity when A. J. Sharpe, a world authority on the subject declares "a critical famine in zinc has almost arrived in Europe as well as in the United States. With production capacity below consumption in Europe, stocks have steadily decreased and prices have just as constantly advanced. European consumption is growing, production is not increasing, stocks are virtually non-existent, so the elements are all present for an excited market."

What Hollinger and Dome are Doing

Hollinger Consolidated production figures to September 9th and Dome Mines results to September 30th, make an illuminating comparison from which it is possible to forecast with the greatest real of their 1922 operations will be. In the nine four weekly periods up to September 9th the Hollinger Company milled 1,016,280 tons indicating for the year 1,660,000 tons. For the fourteen months of the nine periods represented a gross yield of $8,899,758.25, of which $8,573,761.[illegible] Assuming that if the same rate of prosperity is maintained in the remaining four periods the Hollinger Company will come near to the $13,000,000 mark. At the current rate, the year's gross production will be about $12,000,000, of which about $2,[illegible] will be recovered. The average of the grade hereto milled is $8.88 and the working cost $4.14 per ton. With profits exceeding $800,000 per month, and special profits from investments and other sources amounting to $101,[illegible] in the nine four weekly periods, it is natural that the promoters are eager to have "another Hollinger." Net current assets on September 9th were $7,[illegible]. As there is 501,495 tons broken in the stopes, and 2,[illegible] men are employed, the company is fortified with all the power for a greater programme. At this writing the Hollinger mines have accounted for approximately $[illegible] in bullion.

Coincidentally the Dome Mines results are correspondingly flattering. For the half year ended September 30th, the profits amounted to $970,297, which compares with $1,307,275.79 for the whole year ended March 31st. The earnings before deducting depreciation charges and depletion, amounted to $1,230,593, to which other income of $79,561 had to be added. This is by far the best showing made in the history of the Dome Company, with this aggregate record:

Year	Gold Recovered	Operating Expense	Net Operating Earnings
1913	$1,043,994.93	$ 534,038.83	$ 509,956.10
1914	1,204,597.64	615,513.46	589,084.18
1915	1,055,496.78	747,195.70	308,301.08
1916	1,778,958.91	889,594.24	889,364.67
1917	2,171,784.83	1,241,862.15	929,922.38
1918*	1,030,758.30	812,852.16	217,906.14
1919 (Milling Plant was shut down)		237,279.24	237,279.24
1920	1,773,374.44	930,762.31	842,612.13
1921	1,946,403.06	239,508.69	706,894.37
1922	2,809,452.38	1,640,844.90	1,307,275.79
1922 April-September	2,165,384.00	1,230,593.00	970,297.00
TOTALS	$16,980,205.27	$9,120,044.98	$7,508,893.08

* In 1918 the Mill ran only eight months.

The tonnage milled during the past half year was 183,950. The grade of this ore must have averaged about $11.00, for the net average profit per ton was $7.122. This compares with a net profit of $2.819 in 1921. The net yield for September was $8.685.

The combined gold production of the Hollinger and Dome Mines this year will not fall far short of $16,900,000. In that event those two companies will have produced about $79,000,000, of which approximately $60,000,000 will be Hollinger's portion. Both companies are strong in their cash and other liquid assets.

"Another Hollinger has been Discovered"

The "Bankers' Securities Corporation" seems to be a surcharged source of information when it announces that "another Hollinger has been discovered" that

- Geological conditions identical with Hollinger
- Surface showing of ore higher than Hollinger
- Veins larger and values higher than Hollinger
- Ore similar to Hollinger
- Showing better than Hollinger when at similar stage of development.

Rather than squander such an opportunity with a "small initial issue" is contemplated. "Until [illegible] company you will be told about begins to [illegible] supporters."

These alluring inducements appear in the Montreal daily papers. At the same time one of [illegible] papers [illegible] that the public is surfeited with oils and [illegible] schemes, "mining" schemes. Manifestly the [illegible] Securities Corporation" is courting [illegible]. The individuals behind such attempts to [illegible] respect in the "moose pasture" belt of [illegible] Tree prodigy enriched by all the known methods [illegible] deposited [illegible] and then some [illegible] with the Hollinger [illegible] incidentally to obtain small change to [illegible] forget that the public is not [illegible] powers of observation and [illegible] agers of daily newspapers accepting [illegible] probably meretricious, are hardly [illegible] principals among the promoters.

Dome Directors Protest

While Hollinger directors are indifferent as to the claims of catch penny promoters that "another Hollinger has been discovered", directors of the Dome Mines have formerly notified their shareholders not to give heed to representations connecting them with outside mining ventures. At a recent meeting Dome directors fully discussed this matter and vigorous language was employed, because of the impression being cultivated that the Dome organization is officially or unofficially sponsoring certain other enterprises. It is easy to understand why Hollinger and Dome credit should be tapped — but not to the point of discredit.

Mine Labor and Power

Before producing mines, properties undergoing exploration and development, and all the prospects about which their owners are so optimistic can be sure of maintaining or even attaining to their strides, it is becoming a matter of urgent moment that power and labor be provided. A dry season may or may not mean that the North Country will have another of those interruptions which, though temporary, are intolerable. It is a fact that certain of the Mine Managers have been keeping close check on conditions and that they are apprehensive. Daily newspapers clamorous for greater production hardly realize that if Ontario is to be the source of gold to the extent forecasted by them, there will have to be cheap, permanent power, and plenty of it. One power company may not be able to meet the whole situation. As for the labor problem, it looms disconcertingly. Ottawa has promised to modify immigration regulation, but it will have to do so intelligently. There is a shortage of men in the bush. Labor of a kind is lacking. Statesmen and politicians cease to be such and are unpatriotic when they superimpose handicaps on industry, and at a reconstructive time. Chairmen Gary and Grace, of the United States Steel and Bethlehem Steel Corporations, respectively, have publicly appealed for the relaxation of immigration restrictions. This department of *The Canadian Mining Journal* has explained why the largest of steel corporation have raised wages. They felt they had to for more than one reason. President Grace reaffirmed last week the urgency of their needs. In this connection, *The New York Sun* of October 27, had a pertinent paragraph—

"The shortage of unskilled labor, admittedly assuming large proportions, is held by a number of the prominent leaders as the most serious obstacle in the way of prosperity. Judge E. H. Gary, chairman of the United States Steel Corporation, addressing the American Iron and Steel Institute, held the percentage immigration laws as the direct cause. He stated many regarded the law as unreasonable and believes therefore it should be promptly changed. Curtailment in operations and delay in construction work were attributed to the same condition by E. G. Grace, president of the Bethlehem. Industry in this country cannot continue to grow and prosper as in the past, he said, without a substantial yearly supply of new labor. Not a dearth of credit, but a shortage of labor combined with an overburdened transportation system, is the opinion of Col. L. P. Ayres of the Cleveland Trust Company, will serve to end the present rise in this tide of business."

At least two large Ontario gold producers have foreseen the ultimate effect of Ottawa's inhibitions, unless relief be given. Hydro-electric and human power mean more than politics to the whole Canadian people.

"Canada's Century"

Those "doubting Thomases" who frowned upon Cobalt, jeered at Porcupine, pooh-poohed Kirkland Lake, scoffed at Portland Canal, have another chance offered to them in the most recent discoveries of a "fourteen-foot ledge of silver" on the "Big Missouri" the other side of the mountain, across the glacier from the Premier, and of gold and platinum sands in the Fraser River. Porcupine survived its critics; Kirkland Lake, perhaps presents a broader field for wise money. What operating mines there are in Northern Ontario, and what the geological conditions make worthy of effort beyond the pocket books of a Public that is being asked to take cheap script, have "the fecundity of the pack rabbit and the feline" of the domesticated or wild variety.

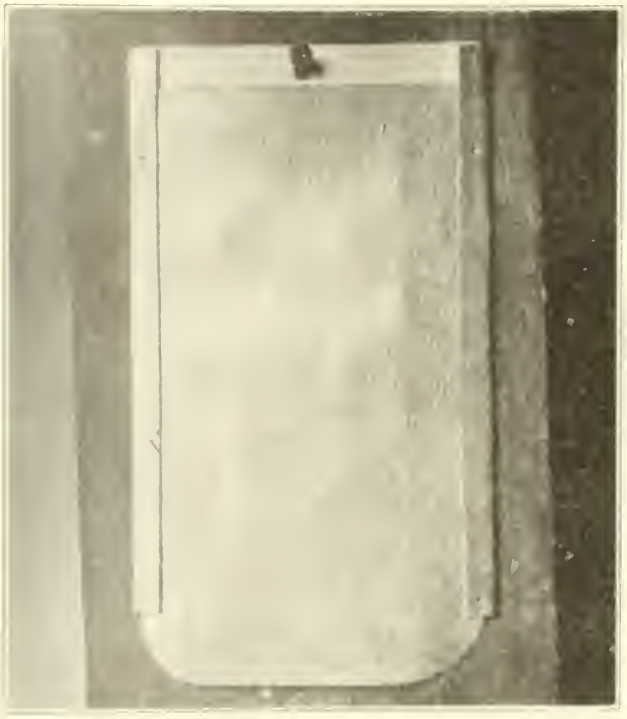
A certain amount of wild-catting is indispensable—if not made too expansive. As evidence of this, there is the experience with the "Big Missouri". It was belauded and belaboured. Holders of options tried and tried again. It met with favor when Neill struck it rich on the Premier, and immediately went into disfavor when New England capital sampled the outcrops. Later Sir Donald Mann, counselled by an eminent Geologist, took it over. The drill was employed, and views regarding secondary enrichment underwent revision. Again there was an abandonment. It reverted to the owner. Then New York interests did some work and dropped out. Finally, the Trites-Wood-Neill-Wilson party seems to have had an eye to windward, being good judges and weather-wise owing to what was learned at the Premier. So the Big Missouri underwent another investigation and it will be all the more interesting to have the details of the find reported in the daily press, to the effect that there is " a fourteen-foot ledge of silver."

Undoubtedly Portland Canal is receiving attention from those American interests controlling the Premier and other properties in the locality, as well as in the Mayo District to the north. The slim pocketbook may not be adequate for the purposes of the Pacific Province, but large ore-bodies and satisfactory values will supply enough magnetism to draw the necessary funds. To be sure, the Guggenheim technical staff will not take a half-portion where a whole meal with the trimmings will make principals more comfortable. As usual, in the meanwhile, Canadian capitalists of the East are rather obsessed with the perennial view that having to do with Mining is censurable, as repulsive as the flesh of a certain international animal is to the followers of Mahomet or those who took their cue from Siani. Of the Fraser River gold and platinum, it is to be said only, that the "bars" may not be so musical as the wires suggest. Considerable platinum has been taken from British Columbia rivers. No doubt there is more where it came from; but fishing in the Fraser has not been very productive in many ways, of late. At any rate, it is possible the platinum will be more plentiful — as plentiful as it was said, a while back, amber was going to be, owing to it being found in sizes of building blocks in a coal mine.

The value of diamonds exported from the alluvial diamond field of British Guiana during the first nine months of 1922 exceeded $2,000,000.

KEEPING STOCK RECORDS CLEAN

A frequent objection to keeping a list of the contents of racks, bins, etc., close at hand for easy reference is that the record sheet soon become almost unreadable by reason of the dirt and grease it collects after a short time in use. It is impossible, of course, for any storeman handling metal to have clean hands and wherever lists of material



and the like are hung up in the storeroom and it is necessary that additional information be added from time to time, some method should be adopted whereby the paper is protected at all times.

A stock record holder that has proved advantageous is illustrated in the accompanying photographs. This holder was made from a piece of scrap sheet brass, one part having both sides bent over and the other piece cut to slide between. Four punch marks provide the necessary friction to hold both parts together. The paper is attached by turning it back over the top and bottom and glueing it to the back. In the first illustration the holder is shown closed, in the second the cover is partly withdrawn, illustrating how the paper is protected from contact with the writer's hand.

A LITTLE TALK ON THRIFT

By S. W. STRAUS, President American Society for Thrift

It is difficult to break away from old habits, and, for this reason the hardest dollar to save generally is the first one.

After the start in saving money has been made, the way becomes continually easier because the new habits of life gradually become more fixed.

The reason many persons do not practice thrift is not that they do not appreciate its advantages, but they never can bring themselves to the point of making the start. It is so much easier to procrastinate and say "next week, next month or next year." But the best time to begin thrift is the present moment. Tomorrow will bring its difficulties, its problems and its temptations. Nothing whatever can be gained by putting off the day of a beginning in thrift.

It should be borne in mind also the amount of money one saves at the beginning is not of importance. The chief factor in the process is making the actual start. After this has been accomplished, one's own enthusiasm will assure the saving of the largest possible sums. It is well to make the matter of saving money a part of one's regular routine. Save systematically.

It also is well to keep a record of one's expenditures. In brief, try to run your personal affairs with much the same accuracy and careful accountancy methods that are practiced by wisely administered business corporations.

Bear in mind as well that, with your resolution to practice thrift and surrender some of the indulgences, pleasures and vanities of life, you will not be the loser in actual happiness. Living beyond one's means without provision for the future does not bring happiness. The sense of security that comes when one really begins to get ahead is a far more substantial and satisfying joy than any that can be obtained from pleasures purchased with money that should be saved.

Make the start in thrift today. Do not be even discouraged if the first sum you save is only a few pennies.

The important question is not how much, but when.

Excitement grows apace as a number of the wells in southern Alberta near the new oil field of Montana near their objective. There is good reason to believe that one or other of these wells will bring in oil. Should oil be found, there will doubtless be a wild stampede to the district as well as a recurrence of excitement in the other presumptive oil fields of the province.

The Smart Turner Machine Co., Ltd., Hamilton, have lately supplied a number of their pumps for mine and quarry use. Mr. H. F. Routley, Toronto, has just installed at his quarry near Caledonia a No. 1 belt-driven centrifugal pump. They are getting out a 5 x 6 Triplex Power Pump for Vipond Consolidated Mines, Timmins, Ont.

Coal Commission in Session

JOHN HAYES HAMMOND DELINEATES THE PROBLEMS TO BE INVESTIGATED

At the three conferences held this week between the United States Coal Commission and the three delegations representing mine workers, bituminous, and anthracite operators, the letter which follows was addressed to each committee. The purpose of the letter as of the conferences themselves was to invite the full cooperation of the coal industry itself. Without exception the response at these meetings with the commission was hearty and such as to promise results in the program to be undertaken. The letter is of such significance to Canadian as well as to Americans that we reproduce it in full.

Gentlemen:

The U. S. Coal Commission appreciates the offer of cooperation on the part of your organization with it in the discharge of the duties imposed upon it by Act of Congress "to investigate and ascertain fully the facts and conditions and study the problems and questions relative to the coal industry with a view to and for the purpose of aiding, assisting and advising Congress in matters of legislation which would insure a supply of this commodity to the industries and the people generally throughout the country and maintain the uninterrupted flow of commerce among the states, or any legislation which Congress may after said investigation deem wise and which under the Constitution Congress has the power to enact."

To this end the Commission very earnestly desires your advice and suggestions, in writing, as to the best means of ascertaining all the facts pertinent to the investigation it has been directed by law to make. The Commission particularly desires your carefully formulated views as to what efficient policy, if any, could, or should be adopted by the Government relative to the coal industry, having proper regard to the interests of the mine worker, the mine operator, and the public. Your intimate knowledge of the conditions which at present obtain in the coal mining industry, your recognition of the principle that there should be a "square deal" for all concerned, and your appreciation of the importance of arriving at the earliest possible date at some policy which would insure an uninterrupted and assured supply of coal at a reasonable price to the consumer, will enable you to render a great service to those engaged in the industry itself and to the nation as well by your cooperation with this Commission in carrying out the functions imposed upon it by the law.

In order to put the matter before you in a more concrete form for your consideration there is attached hereto a sheet giving the various topics upon which the law creating this commission requires it to develop facts or make recommendations.

The Commission desires you to go carefully over this list of topics and advise it in writing at your earliest convenience on the following points.

(a) What specific data should be secured under each one of the topics enumerated in the law in order to carry out adequately the direction of the law?

(b) What, in your judgment would be the best and most practicable method for the Commission to adopt for securing these data?

(c) What, if any, topics should the Commission investigate in addition to those already enumerated in the law, in order to give to Congress and the public complete information necessary to the proper understanding of the conditions in the coal industry?

(d) To what extent are you in a position to co-operate with the Commission in securing necessary data in such manner as will eliminate in the largest possible degree any basis for criticism of the accuracy or the validity of the data which have been secured?

In addition to the above the Commission further desires you to advise it in writing at some date in the near future, tentatively:—

(e) What, in your judgment, are the elements that have caused and are causing the acknowledged demoralization in the coal industry, and which are working hardship alike upon the parties engaged in the production of coal and the consuming public?

(f) What, in your judgment, are the practical remedies that would eliminate any or all of the elements that you feel are responsible for the condition?

Respectfully,
John Hayes Hammond
Chairman

LIST OF TOPICS

1. Ownership and titles of the mines; 2. Prices of coal; 3. The organization and persons connected with the coal industry; 4. Cost of production; 5. Profits realized by operators or owners of said mines during the last ten years; 6. Profits of other persons or cooperation having to do with production, distribution or sale of coal; 7. Labor costs; 8. Wages paid; 9. Wage contracts; 10. Irregular production. 11. Waste of coal; 12. and suggestions as to the remedy for the same; 13. Conditions generally under which coal is produced; 14. Distribution.

15. The causes which from time to time induce strikes, thereby depriving interstate carriers of their fuel supply and otherwise interrupting the flow of interstate commerce;

16. and all facts, circumstances, or conditions which would be deemed helpful in determining and establishing a wise and efficient policy by the Government relative to said industry.

17. Standardizing the mines upon the basis of their economic productive capacity and regarding the closing down of mines which by reason of their natural limitations or other conditions, fall below the standard.

18. Ascertaining and standardizing the cost of living for mine workers and the living conditions which must be supplied or afforded in order to surround the workmen with reasonable comforts and standardizing also as far as practicable the amount of work a man shall perform for a reasonable wage, recognizing the value and effect of such surroundings in respect of their efficiency.

19. Standardizing a basis of arriving at the overhead cost of producing and distributing the coal, including delivery at the door of the consumer, recognizing in this compilation that the standardized cost of living to the miners should be the first and irreducible item of expense.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

PROVINCIAL TAX—It is officially stated that the Government has no idea of increasing the mining tax at the present time. Some who were supposed to know about these things have been greatly concerned the last few weeks over a report that the Government proposed to increase mine taxes on a sliding scale that would bear most heavily on the largest and most profitable mines.

GOLD IN QUEBEC—New discoveries of considerable importance are reported in the Township of Ruyon in the Province of Quebec a short distance East from the Ontario border. A couple of months ago the property known as the Horne Claims was found and optioned to the Thompson-Cadbourne interests. Men were sent in to open up this property and although the results were not very encouraging, it did lead to the new discoveries some little distance away. It is understood that the vein has been traced for practically two miles in length, and that where uncovered it shows an average width of about six feet and assays approximately $8.00. As mining claims in Quebec can be staked to embrace 200 acres, it did not take long to blanket this particular discovery and put the claims in the hands of a very few people. A considerable amount of work will be done during the coming winter and the result of operations there will be awaited with keen interest. The discovery appears to be the most important since the discovery of Kirkland Lake.

POWER FOR KIRKLAND—Kirkland mines are still waiting for power, but should receive it some time during the week beginning November 1st. When the power company was able to supply sufficient electricity for pumping and lighting the mines, it seemed better to make a permanent job of repairing the burned sections of the power line rather than to make a temporary job that might give out at any time, and this has necessarily taken longer.

NEW HOIST—Kirkland Gateway has purchased a larger hoist to permit of the increased operations on its property.

BROCK—The Boland has cut its main vein at 600 feet, but no information is yet available as to assays.

OPTION PROMOTES—The Thompson-Cadburne interests have dropped their options on the Elsto-Dunkin and the United Kirkland properties. It is understood that while results were encouraging they were not good enough to justify the heavy cash payments due under the options, and as some defer could not be arranged the options were allowed to lapse.

KING KIRKLAND—The King Kirkland is crosscutting at the 100-foot level in an effort to locate the main vein at this depth.

RICH KEEWATIN ORE—The Keeley property in South Lorraine has some remarkable ore and in the new shoot recently discovered the vein in places shows a width of 12 inches and carries up to 15,000 ounces. Production is being maintained at about $80,000 per month, and it is understood that substantial reserves are being blocked out.

VIPONT UTAH—A large part of the revenue of the Kerr Lake Mine comes from the Vipont property in Utah. During the year ending August 31st the latter property produced 997,666 ounces of silver.

NEW VEINS ON PRINCESS—Recent developments of the Princess property by the La Rose have resulted in the discovery of several small veins in territory that hitherto has been practically unprospected.

HOLLINGER—In an effort to cope with the possible shortage of skilled miners, the Hollinger has arranged to bring men out from England, and it is understood that there are now one hundred Cornishmen on the way. Officials of the company announce that no dividend increase will be made this year. This may perhaps be in view of possible power shortage, which would result in curtailed operations and decreased profits. A few days ago a very unusual accident happened at this property. A storage battery locomotive and two cars, one empty and one full of steel, were standing on the 4th level. The operator intended to send the steel car to the steel rack, but apparently must have turned the control the wrong way, and the two cars, with the locomotive behind, shot into the shaft compartment, down which a cage load of men had just descended. Eighteen men were on the cage when the cars and the locomotive went down the shaft, and the surge on the rope caused the safety dogs on the cage to set, fortunately just above the 600-foot level, where they were able to get the men on the station. If the dogs had caught further up the shaft the only way they could have got the men off would be to cut through the side of the cage with acetylene torches. Six men are in the hospital, one with a fractured skull, while all were more or less burned with the solution from the electric storage batteries. Although the locomotive was too large to go on the cage and the two cars went down the shaft ahead of the locomotive, when the wreck was removed it was found that the empty car was on top. As the locomotive fell approximately 200 feet, the shaft was badly damaged as well as the locomotive. It is estimated that the repairs to the locomotive alone will cost approximately $5,000.

DOME—The report of the Dome for the six months ending Sept. 30th shows a profit of $970,000 after large allowances for depreciation of plant, machinery and exhaustion of minerals. Profit compares with $1,215,000 for the entire previous year and shows an increase of approximately 55 per cent. Although a repayment of capital of $1.00 as share was made and the dividend was also doubled to $2.00 a year, the surplus was increased from $215,000 as of March 31st to $712,000 as of Sept. 30th. Call loans are shown at $550,000, bonds at $1,610,000 and cash on hand at $378,000. Reserve for depreciation on plant, machinery and mine exhaustion now stands at $3,000,000, which is over 70 per cent of the paid up capital. Although the recent profit-sheet pocket was small, it is understood that the ore exhibited $50.000 a ton.

NEWRAY—Comagas has completed four diamond drill holes on the Newray property, and other holes are under way. No official word has been given regarding the results.

Porcupine Power Shortage.—Unless there is further rainfall in the Porcupine district, the power situation during the coming winter is liable to be serious. The supply of power is already short, and pending the completion of the Sturgeon Falls plant, which will probably be ready in January, no new contracts are being made.

North American Gold Corporation.—One of the latest stock offerings to the public is that of the North American Gold Corporation, with offices in New York. While literature sent out from the company's offices does not actually state that the property is greater than the Hollinger or Dome, it implies that it will be. The literature also implies that the North American Corporation owns the property, but this is not the case, and the public is being asked to put up money not only to buy the property but also to finance a mill. The property comprises what was formerly known as the Ankerite claims in Deloro Township. This property was under option to the Coniagas for a long time, and the Coniagas spent approximately $300,000 in endeavoring to find commercial ore bodies. Although the company had already paid a certain proportion of the purchase price, they did not presumably, consider it worth while, even in the face of the heavy expenditures already made, to complete the purchase and were content to take their loss and let the option drop. The North American Corporation estimates ore reserves of $6,000,000 above the 300-foot level, but in view of the action of the Coniagas management, these figures must be taken with a large grain of salt

BRITISH COLUMBIA

Cariboo.—J. D. Galloway, government mining engineer, thinks that the old Cariboo, the historic gold country of British Columbia, is "coming back". He states that there is gold at Cedar Creek, that it is found on the high benches, seven hundred feet above the present creek level—a most unlikely place to look for the precious metal. One company, with an option on two leases, took out thirty ounces in a day. A steam engine is being installed to pump water from a reservoir for the sluice boxes. Adjacent ground is to be opened up on a large scale and men now are working in preparation for the installation of a plant of considerable size. Mr. Galloway has been supervising some diamond drilling of an exploratory character being carried on by the government on what is known as the Waverley Group of claims.

Usk.—The high benches along Gold Creek, near Usk, northern British Columbia are reported to be yielding gold. Six leases have been recorded and other staking is going on. Two or three companies have taken steps to explore the gold area thoroughly. Gold has been taken from the creek bed for years but the possibility of the benches containing values never before occurred to prospectors.

Rossland.—The last shipment of ore from the I. X. L. Mine, Rossland, which is being operated by a syndicate of local miners, is reported to have brought over $12,000. One car of ore was sent to the smelter.

Molybdenite, Kaslo.—Samples of ore running over $20 a ton in gold and containing a fair amount of molybdenite have been brought to the town of Kaslo by D. Waddams of Johnson's Landing. He says that he already has a carload of this mineral ready for shipment. There is said to be a 12-foot vein.

Kaslo.—The Utica Mines near Kaslo will be taken over by Major H. H. Armstead, a mining engineer of New York. His offer is 7½ cents per share at the end of twelve months, giving the stockholders the alternative of taking stock in the Armstead mine or cash. Major Armstead has lately been identified with a property situated at Talache, Idaho, which under his management now is upon a dividend earning basis. He proposes building up the Utica Mines in the same way, it being his intention to acquire other properties for development simultaneously with the Utica.

Silver Strike.—James Currie reports having struck 14 inches of dry sulphides on Woodberry Creek, carrying values in silver varying from 100 to 950 ounces per ton. Several tons are sacked and ready for shipment.

Slocan Shipments.—A revival in mining throughout the Slocan district is predicted. The Silversmith Mine shipped 700 tons in September and has sufficient ore in sight to continue regular shipments over a long period. The Ruth Mine, now under development, is showing up satisfactorily and the force of men employed is to be materially increased. An important strike is reported to have been made on the Reco. A new lead has been uncovered carrying more of a dry ore than usual, which contains a considerable proportion of grey copper. The Silverite, Black Colt and Carnation are all prospects of promise. A lease had been taken by operators on the dumps of the Sovereign mine, a carload of which material has been shipped. The Noble Five mine at Cody shipped 10 tons of zinc ore in September and is expected to be permanently re-opened in the spring. The Noonday Mine has been opened and expects to ship a carload of ore before winter. The Surprise and American Boy Mines are working under lease. A long tunnel is being driven on the McAllister property and the work will be continued until its objective is reached.

Big Missouri.—Development work on the Big Missouri, Portland Mining Division, Northern B. C., will be continued throughout the winter months. Indications are that it will be possible to commence shipment of ore at an early date. The intention is to transport the material over the trail which was constructed this summer, by double-ended sledge.

Esperanza.—Approximately 100 tons of second-grade ore is being shipped from the Esperanza Mine, Alice Arm to the Granby Smelter.

Boundary.—After more than three years inactivity, the Boundary Red Mountain Co., whose property is practically on the line between the State of Washington, Whatcom County, and the Province of British Columbia, has resumed operations. This property was taken over by Mr. George Wingfield of Nevada, President of the Goldfield Consolidated Mines Co., in 1915. Considerable development work was done with results that led to the installation of a 50-ton mill and an adequate power plant. During 20 months of mill operation extending well into 1917 the gross production amounted to more than $280,000. The work of proving the principal vein from the 200 to the 500ft. level was completed in 1918, opening up large ore reserves. A geological survey recently made has satisfied the management that the ore will continue to greater depth and plans are now under consideration for a new tunnel, 700 ft. below the present 500 ft. level.

Trail Ore Receipts.—Ore receipts at the Trail Smelter, Canadian Consolidate Mining & Smlting Co. for the second week in October were 7565 tons. The shipments

included: Alamo, 151 tons; Black Rock, Northport, Was. 72 tons; Etheopia, Greenwood 4 tons; Monarch, Field 44 tons; Mountain Chief, Rerata 23 tons; Noble Five, Sandon 92 tons; Paradise, Invermere, 40 tons; Quilp, Republic, Wash. 53 tons; Silversmith, Sandon 199 tons; Surprise Republic, Wash. 54 tons; Silver Hoard, Ainsworth 38 tons; and Company Mines 6853 tons.

TESTING PLANT FOR B. C.—The establishment of a plant for the experimental testing of the complex ores of British Columbia has been favorably considered by the Dominion Government. Such an installation, costing approximately $100,000 will be provided for in the estimates at the next session of the Federal Parliament. This has long been agitated for in this province. At present mines operators must send their ores to Ottawa for treatment and the service, it is stated, is far from satisfactory. With a plant engaged on British Columbia minerals exclusively it is thought that information could be more readily obtained as to the best methods to be adopted for the economic treatment of refractory ores of the Kootenay as well as of other mineral bearing sections of the Province.

NOVA SCOTIA

MOVEMENT OF COAL.—Coal shipments eased up somewhat during the week, affecting some collieries, which had broken time. These were largely in the Glace Bay and Sydney Mines districts. The collieries of Pictou and Cumberland have contracts which will give steady employment to the end of March, 1923.

CAR REPAIRS.—The Trenton Steel Plant is busy on a 500-car repair order from the Canadian National Railways. In repairing the steel cars an average of four tons of new steel is being used and this will further business has made busy times.

PROGRESS REPORTED AT No. 26.—Operations on the large colliery at Dominion No. 26, which for upwards of a year have been held up have started up and the shaft will be rapidly pushed down to completion. This looks as if "Besco" has sufficient money without having to borrow from New York. Other undertakings on a large scale have been commenced lately.

WABANA ORE SHIPMENTS.—The ore shipments from Wabana to Sydney to October were 71,000 tons. An average of 5000 tons of ore was loaded at Wabana piers each day that ore was operated. Of the amount shipped 4000 tons recently was drawn from the stock piles and 4000 from the mines. Between now and Christmas shipments of ore are from Wabana to Sydney are expected to reach 150,000 tons.

THE LIMESTONE QUARRIES.—As large quantities of limestone will need to supply the Sydney steel plant up to next June have been stocked at Sydney, the Port au Port limestone quarries have been shut down for the winter. Some activity may have been kept on for a month to make certain of the next year's operations.

GOLD REPORTED AT LABRADOR.—In Newfoundland considerable interest is being shown in the reported gold discoveries at Star Creek, Labrador. Large areas have been taken up by Montreal men and claims are being staked out. As a result quite a great amount of capital will be required to develop. Aeroplanes are said to be in use in connection with the taking up of the claims. In this district the spring is a little late, but the summers are hot. The weather being fairly comfortable for at least six months of the year.

WABANA ORE FOR GERMANY.—The October iron ore shipments from Wabana, Newfoundland, to German ports was 102,000 tons. By the end of the shipping season, which comes about Christmas, the quantity of iron ore shipped from these mines to Germany will total 735,000 tons. In the interval 200,000 tons will be shipped to Emden. The freezing up of German ports prevents winter shipments.

Book Reviews

THE MINERAL INDUSTRY DURING 1921. VOL. 30.—edited by G. A. Roush.—McGraw-Hill Book Company, 370 Seventh Avenue, New York.—895 pages. Price, $10.00.

The thirtieth volume of this standard annual work has just reached us. It is, as usual, so compendious and so obviously authoritative that it is beyond the capacity of any but a genius or a specialist to commend it or criticise it; hence a few general observations must suffice in the present case. A scrutiny of the list of forty three contributors to the volume, each one with special knowledge of the mineral he discusses, is sufficient to demonstrate the dependability both as to information and opinions set down, of the book's contents. Mr. Roush has had an eye to head presentation as well as to sound matter, for his book, highly technical as it must necessarily be, is eminently readable.

Canada is represented in the list of contributors by Dr. C. W. Drury of Queen's University, who treats of cobalt, and by Mr. Thomas W. Gibson, Deputy Minister of Mines, Toronto, who reviews the nickel industry.

Canadian mineral production is prominent in several of the sections. The white arsenic production of 1,491 tons from Cobalt ores was, in 1921 one-quarter that of the United States. In former years it has been about one-fifth of the world's total. It is predicted that the annual consumption of arsenic will increase; but there is arsenical ore available to meet any probable demand.

The Quebec asbestos field still dominates the market, though the lower grade blue asbestos of Rhodesia is finding a wider market each year.

The copper production of the United States dwarfs that of any other country. Nevertheless Canada's principal producers are notable, even during the worst year the copper industry has ever had. The Granby plant at Anyox, the Trail smelter and the Sudbury plant yield the respectable total of about 50,000,000 pounds.

In 1921 Canada produced one sixteenth of the world's gold and one twelfth of the world's silver. Ontario's rising production of gold and its steady output of silver are the principal features, while the potentialities of the Portland Canal and Keno Hill districts in the Yukon have begun to loom large.

In the progress of the iron and steel industry [illegible] the most important of all the mineral industries, Canada [illegible] Canada also ran. The success of the Ard[illegible] electric steel furnace, a Canadian development, [illegible] new and promising process for smelting titaniferous ores, also worked out in Canada, [illegible] considered worthy of special note.

In lead and zinc the outstanding [illegible] Mine [illegible] worthy of international attention. The [illegible]

tallurgists who have solved the difficult problem of using the complex Sullivan ore receive special commendation.

"Canadian phlogopite continues to supply most of the world's 'amber mica,' which is preferred for certain electrical uses." The production in 1921 was 700 tons.

Nickel and cobalt, virtually monoplises of Canada's need no special discussion here.

In the resume of progress in ore-dressing and coal washing, the rod mill is discussed at some length, and the economies of its use (not yet fully demonstrated) are mentioned. The re-discovery of the Torrey Cyclone for liberating asbestos fibre from rock is noted. The remarkable progress of selection flotation is discussed. The flotation plant at Nanaimo is the pioneer in the commercial use of this process for cleaning coal.

THE MINES HANDBOOK, 1922—VOL. 15—by Walter Harvey Weed—The Mines Handbook Co., Tuckahoe, N. Y.—pp. 2248. Price $15.00.

The Mines Handbook originated as *The Copper Handbook* by Horace J. Stevens in 1900. Stevens was a noted writer on mining topics and investments and the book was an outgrowth of his work for the technical papers. In a few years time, the book became the standard authority on Copper Statistics and on Copper Mining companies, as Stevens did not hesitate to call a fraud by its right name and to express his frank disapproval of companies organized to sell stock and not for legitimate mine development.

The book has grown from a modest 200 pages, to the 1922 volume of 2400 pages. The original book dealt only with the Copper Industry. The present Mines Handbook covers the entire metal mining field. Carefully compiled and conscientiously edited, analyses of all available information are given for every active company and the opinions expressed are given without bias, fear or favor.

The book contains information about several thousand mining companies, that cannot be found in any other publication. Canada is represented on pages 1691 to 1867, the bulk of the companies listed being, of course, in British Columbia and Ontario. All incorporations that remain uncancelled are given, and consequently the operating mines represent only a small minority of those listed. The discerning reader will find a deal of information, both explicit and implied, in the few lines devoted to each company.

We can heartily commend the work to investors, stock brokers, banks, machinery manufacturers and in fact to all who are interested in the business of metal mining or the value of mining shares.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch). $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclosed ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

CHEMIST, experienced in blast furnace and steel plant work, ores etc., desires position. References. Address Box 521, Canadian Mining Journal, Gardenvale, Que.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertiserswill be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eighthpage, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale,Que., who can in all probability, refer them to proper sources.

EDITORIAL

There are some subjects with which governments can give assistance, and their assistance is always welcomed; but the mineral industry is one that does not flourish under paternalism, and advice such as has sometimes been offered in this country is not welcomed.

"How small a part of all that we endure
Is that which governments can cause or cure."

W. G. Miller 1910.

WHY PUBLIC SUBVENTION?

We quote today, above, the words of a leader in the mineral industry of Canada whom time has proved to have both sound judgment and prophetic vision. The quotation is apt today on account of a present case in British Columbia to which it appears to apply with a force equal to that in its original context. The prospective iron ore industry of British Columbia is in danger of being subjected to highly artificial and paternal treatment, such as has been shown often to be in opposition to the genius of British commercial life, and seldom leads to a good and lasting result of maximum benefit to the community that has footed the bills.

British Columbia has iron ore and plenty of it. For a generation or more, the owners of a number of first class deposits of magnetite on the coast and coastal islands have paid taxes on their property in the hope that there would be developed a market for it. A number of these owners have expended large sums of money in developing their ore bodies, and are not only willing but anxious to realize on their investment either by selling ore at a reasonable rate or by selling their holdings. Metallurgical coal is available at tidewater in comparative abundance. Hydro-electric power (if that should be required) is available on the mainland at fairly reasonable rates, though only in quantities that might not be adequate for large electro-metallurgical operations. British Columbians do not lack the initiative that leads to the utilization of natural resources such as these. What is lacking to stimulate their use?

Apparently it is the lack of an adequate market that has deterred all the numerous commercial interests that have investigated the field from investing their money in a Pacific iron and steel plant. The capacity of this market has been ably summarized by Dr Stansfield in his report to the British Columbia government in 1919. It is merely adequate to absorb the products of an electric smelting plant, but that is quite a different dimension from the requirement for a regular blast furnace plant. It has been proposed to include in the market available for a smelter in British Columbia, the western United States; but that is obviously unsound, as it is the avowed and consistent policy of the United States to exclude manufactures from foreign countries as soon as their importation interferes noticeably with domestic manufacture. Similarly there is no substantial prospect of a trans Pacific export market, as the iron and steel production of India, founded upon unsurpassed resources of iron ore and cheap metallurgical coal and labour, has commenced already to demonstrate its ascendancy in that quarter of the globe.

There is no doubt that, if there were a genuine opportunity for lucrative investment in a modern blast furnace and steel plant in British Columbia, one or other of the iron and steel firms that have examined the field during recent years would have seized it. There is likewise no doubt that British Columbians can institute such an industry if they are willing to pay the price. The danger is that specious argument, directed by selfish interest, may blind them to the truth and may commit them to a course that will add to their financial burden without the certainty of effecting the end they all desire. If the half million population of the Pacific province were augmented to say, two million (as it will be, no doubt, before the present youth of the province have reached old age) then the risk of public funds in the establishment of an iron and steel industry might well be justified.

Meantime, it seems more reasonable to look for the establishment of the much desired plant by some other means more in accord with present conditions. A short time ago it appeared as if the small-scale production of an electric smelting plant might be feasible, and only the non-availability of cheap electric power prevented its recommendation by Dr Stansfield. It might well be that a commercially successful electrolytic process will be discovered whose comparatively small unit production would suit the needs of British Columbia's sparse population. We believe that until the province's own need is sufficient to absorb the production of an iron and steel plant of the regular type, effort will be best expended in the search for a method of producing iron from its ores that is [illegible] in accord with all the important factors of the case.

A PUBLIC DUTY

Last week we noted the fact that the coal miners of Alberta and eastern British Columbia have given notice of a further demand from the public in the way of a six-hour day and a five-day week, with a continuance of the present weekly rate of wages. We pointed out that although the public is the owner of the coal seams and, as consumer, is the party principally concerned in the cost of producing the coal, it has not, heretofore, been adequately represented in the councils where wage rates are decided, and will remain unrepresented in the present case unless definite and decided action is taken.

Those who uphold the efficacy of our Arbitration Act to settle disputes must needs confess that, though its provisions have ended many a wages dispute, these settlements have been made almost invariably at the expense of the public. The Act provides for the representation of the interests of employer and employed, and an unbiased third member. The public has no representative instructed to plead its case and protect its interests; hence the public has suffered, and suffered severely.

In the United States, a Commission composed of eminent men of various professions, truly representative of the interests concerned and well qualified to investigate thoroughly and adjudicate fairly, have been left with the coal problem for solution. Whether they will prove to be the exception to the long succession of commissions and committees that have investigated and reported, without avail, only time will tell.

The coal strike in Britain last year was settled by a means that appears, up to the present, to have realized the expectations based upon it more fully than any similar method. The mine operators, faced with the necessity of meeting international competition, tried to reduce prices from their war-time peak. The miners, puffed up by their easily-won victories over the owners in the time of national stress, refused the lower wage. To overcome the impasse, the public, represented by a committee of Parliament, stepped in, and imposed terms that provide a fair rate of return to capital, that give to labour all it can earn and encourage it to further exertion for further gain, and that allows of the gradual and certain rehabilitation of the industrial life of Britain, based as it is to such a marked degree upon the product of the coal mines. This settlement has provided a most clear-cut example of the power of public sentiment, when it is roused to the point of action. It also gives to us Canadians a pointer as to how we can, if we will, adjudicate in our own case.

We, the public, must have a representative in future important industrial disputes. Many of us assume that, since the Industrial Disputes Act is an act of our elected Parliament and is administered by public servants and Ministers of the Crown, we are already adequately represented. The event has proved the contrary. If our Parliament is anything more substantial than the shadow of what it is supposed to be—if it comprises even a modicum of men (including the lady, but excluding those whose self-revealed tendencies place them in a lower category)—then it is capable of presenting our case, and of seeing that our interests are adequately served in the issue. It has been done in Britain and, unless our Canadian parliamentary institution is a farce, it can be done here.

There devolves upon the public, however, a very definite duty. We must let our elected representatives know that we are interested in this coal question—one of the principal concerns of our economic life—and we must give them the mandate without which we cannot expect them to act. The press is the chief instrument to arouse and organize public opinion. Upon the public press, then, rests this duty.

MINING-SHARE QUOTATIONS IN LONDON

On numerous occasions we have referred to the advisability of interesting British capital in the Canadian mineral industry in such a way as would be to the benefit of both. There has been evidence lately that the desirability of this is realized clearly on both sides of the Atlantic. So far, practical expedients have failed to keep pace with the idea. We wish to present here a practical expedient, not new, but capable of application at this time.

A Canadian, prominent in mining affairs, writes: "It is regrettable that, while there are daily quotations of South African mining shares, Australian, and so forth, in London, there are few shares of Canadian mines quoted. The following note is from the *London Mining World* of October 7th, 1922:

> 'The market in Canadian gold-mining shares is mainly confined to the United States and Canada, though our readers are fully aware that it is spreading rapidly to London—almost week by week.'

"There is no doubt that the market for Canadian shares would be much enlarged were there daily quotations of prices. It would be of much advantage to the gold-mining industry in Ontario to have conservative investors in the British Isles purchasing shares."

A scrutiny of a recent listing of Canadian securities in London shows six mining companies in a close-printed page — and one of these six is mis-placed, as it belongs to Colorado, not Canada. Another page of mining shares, representing properties almost exclusively within the British Empire, is graced by two Canadian mines.

At one time there were few, if any, Canadian mines that we could honestly recommend for listing on any well-conducted stock exchange. This is no longer the case. Though there is a multitude of flotations that would disgrace us abroad, as they do at home, we have now a large number of mining companies well worthy of representing the Canadian mining industry in London. Indeed, the affairs of some of our mining companies are so arranged that they give promise of dividends, if not in perpetuity, then as long as many industrial concerns with favoured places on the stock exchanges.

We hope that this matter will receive the attention of those whose concern it is to forward the interests of the best British mining stock exchanges. We are confident that these exchanges and the Canadian mining industry have a mutual interest.

PROFESSIONAL MINING ENGINEERS

Four weeks ago we discussed, under the caption "Institute Membership", the broad question of Institute policy in this important matter, and proposed that the subdivision of professional members, recently instituted and now fairly comprehensive in its membership, be made to serve certain ends of all professional mining engineers, and particularly of those that wish to have a purely professional Institute. Since that time, we have learned something of the origin of this movement within the Institute.

Fifteen years ago, or more, one of the charter members of the Institute, then, as now, one of its most active and most loyal members, and now a past president with an enviable record of service, brought forward this idea of forming a professional section to which only well-qualified engineers could gain admittance. At that time there was being brought to bear on the provincial and federal governments very strong pressure to force the enactment of a professional engineers' bill with exclusive provisions. It was mainly through the efforts of the Institute that this attempt came to naught. Then, as now, the logical alternative was to form a professional society composed exclusively of mining engineers to administer the affairs of the profession. This proposal was not incorporated in the by-laws until 1919, since when our secretary has vigorously put it into effect, so far as enrolment can do it.

But our progress has stopped. We have halted by the wayside. This enrolment is only the first step, and we have still a long way to go. We have now supplied the means to our end: let us effect that end.

Our profession needs regulation, as does any other. We prefer this regulation to be in the form of self regulation, imposed on ourselves by ourselves and by no one else. It is, no doubt, this worthy feeling of independence that has led mining engineers so generally to resist the enactment of a law that would regulate the practice of all branches of engineering. Regulation is necessary, and we have failed to impose it upon ourselves thus far; therefore it behooves us to adopt, without delay, some effective measure.

It is obvious that the logical procedure is to complete the measure inaugurated in the Institute fifteen years ago, formally adopted in 1919, and still waiting to be applied with its full effect. The measure was designed expressly for the object of regulating the practice of mining engineering throughout the Dominion. At present it is a dead letter so far as this, its prime object, is concerned. Meantime the effort and money expended on it are without avail. This is poor sport; let us, at least, get a run for our money.

EDITORIAL NOTES

Today we print a letter from Porcupine that registers a decided objection to our recent rather pessimistic editorial remarks on the forthcoming new report of the district. The writer, who is intimately acquainted with the methods of the field officers of the Ontario Department of Mines and the facilities at their command, predicts a prompt report. We sincerely hope his judgment is correct. It is quite possible that we have over-estimated the magnitude of Mr. Burrows' task and have under-estimated the amount of assistance he will receive from geologists in private employ.

The shortage of unskilled labour in the United States, which becomes more acute week by week, seems likely to spread to Canada. It is already noticeable in some of the mining camps. It is a question how far this shortage can be met under the present immigration regulations. It is likewise doubtfull if unrestricted immigration from Great Britain would provide men able and willing to meet this need.

THE FOURTH ANNUAL GENERAL WESTERN MEETING OF THE CANADIAN INSTITUTE OF MINING AND METALLURGY 1922

PROLEPSIS

Where the Pacific laves Columbia's strand,
(And more than laves when it gets out of hand
There, on the fifteenth instant, hand picked brains
A precious freight, brought in by many trains,
Forgather at Vancouver. Wide, O! wide
The range of talent that will there provide
The feast of reason and the flow of wit.
Cloud-piercing Spike will surely make a hit;
Wilson, the Archimandrite, (than whom none
Is fonder in a quiet way of fun)
Will fill the chair with grace and with aplomb,
Enforcing discipline as with a bomb.
Kirkpatrick, Brewer, Guernsey, Leckie twain,
Will see to it that things proceed amain
There'll be no lack of stimulating thought (in)
Tricks from the Bible will be played with wit (in)
I have no smallest doubt that rank sedition
Will be the rule respecting prohibition
And now, as ever, when the curtains fall,
The Meeting will be voted best of all!

* * *

One thing I ask before the Meeting closes—
It is that some one rises and proposes
The silent health of those who, now departed,
Courageous, cheerful, ever open hearted,
Kept the lamp burning through the anxious years,
Cherished their faith and straight forgot their fears!

J. C. M.

Placer Deposits of Cedar Creek Area, Cariboo District, British Columbia*

By W. A. JOHNSTON

The discovery in the autumn of 1921 of placer gold near Cedar creek in the Cariboo district, British Columbia, caused a rush of prospectors to the area in the spring of 1922. Considerable prospecting was carried on throughout the area during the spring and early summer in an attempt to extend the known area of placer ground but by mid-summer most of the prospectors, disappointed in their search for gold, had left the area. No important new discoveries were made outside the original area but mining and prospecting in the vicinity of the orriginal discovery resulted in the finding of pay gravels which are much richer and of different character from those originally found. This discovery was made late in the summer and has served to revive interest in the area and to raise the question whether the deposits will not eventually prove to be of considerable importance. The fact that the pay gravels are found at a high level above the present drainage also renders the occurrence of exceptional interest. Few if any similar occurrences were formerly known in the region but if one is established beyond doubt and proves to be of value there seems no reason why others should not be found when the area is thoroughly prospected.

The writer examined and mapped the Cedar Creek area in September, 1922. Acknowledgments are due to Mr. C. Muir, Mr. R. N. Campbell, Mr. E. G. Stevens, Mr. R. Graham, Major M. S. Day and other mining men and prospectors for information regarding placer mining operations and prospecting in the area.

Accessibility of Area

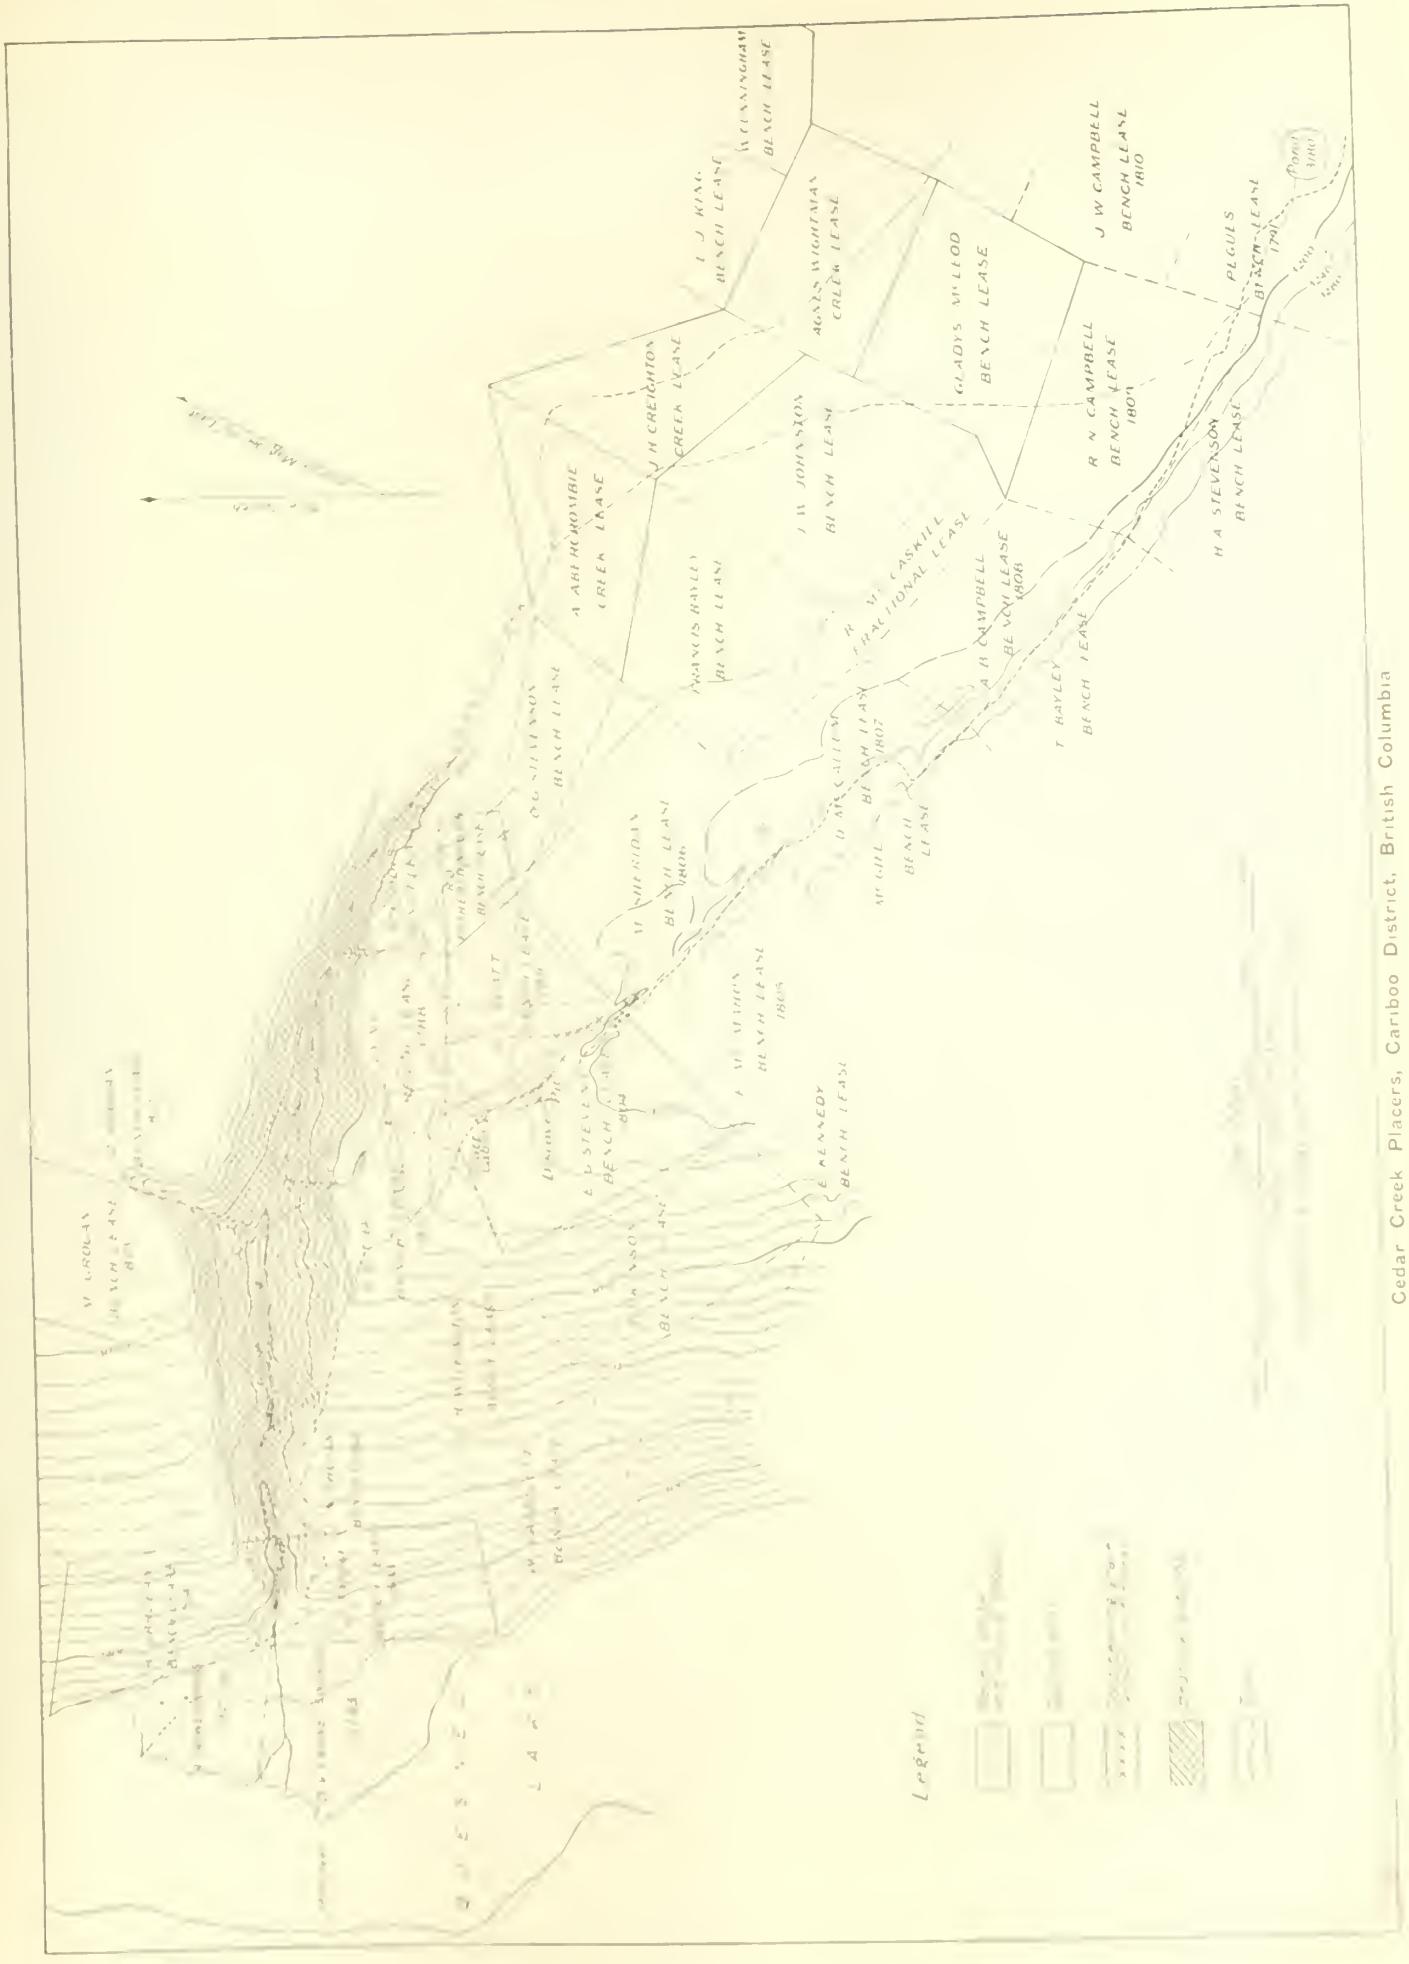
Cedar creek is a small stream flowing into Quesnel lake from the east about 3 miles above the old dam at the foot of the lake. The lake is situated in the south-central part of the well-known Cariboo district of British Columbia. A road, passable for automobiles, runs from Williams Lake station on the Pacific Great Eastern railway to the dam where a townsite, known as Quesnel Dam, is laid out. The road passes through Quesnel Forks at the junction of the North and South Forks of Quesnel river and thence along the north side of the South Fork to Quesnel Dam, the distance from Williams Lake to the Forks being 64 miles and from the Forks to the Dam 7 miles. Another road which ends on the south side of the river at the Dam runs from near Bullion and is shorter than the road via Quesnel Forks, but there is no bridge across the river at the Dam and the Forks road is generally used. Boats are employed for transportation from the Dam to the delta at the mouth of Cedar creek, and a wagon road is being built from the delta up to the mines. A hotel, general store and a number of residences have been built at the Dam and along the shores of the lake, and there are a number of motor boats on the lake.

Physical Features

The topography of the Cedar Creek area is in general similar to that of the Quesnel River and Quesnel Lake districts. The present stream valleys are, for the most part, narrow and deep and steep-sided. Some of the valleys, in their upper parts, are broad and flat-bottomed, and parts of the upland about 1000 feet above the lowest parts of the main valleys are nearly level. This shows that streams formerly flowed at about the level of the upland surface or plateau and that the present valleys have been cut down below the old drainage level, probably because of uplift of the region. In places only small remnants of the old plain-like surface at a high level are preserved; in other places they are quite extensive. Isolated hills and ridges — for example, Spanish mountain, east of the headwaters of Cedar creek, — rise 1000 feet or more above the plateau level. These hills are erosion remnants, and prove that a great thickness of the bedrock has been worn away. The recognition of the old plain-like surface at a high level is of importance in prospecting for placer gold, for it is reasonable to suppose that parts of the channels of the ancient streams would be preserved. It is to be expected, also, that the ancient streams had low gradients and that, therefore, if an ancient stream channel be located its continuation should be looked for at about the same level. A factor, however, which must be considered is that the region was glaciated and, as most of the placer gold was formed before the Glacial period, it is probable that the pay gravels were in part eroded by the ice and became mixed with the glacial drift or were transported by the ice for some distance from their original resting place. The work done in the area is not sufficient to determine what were the effects of glaciation, but glacial drift occurs abundantly from the lake level up to altitudes of at least 3300 feet. It forms a blanket over most of the area and conceals the bedrock except in the canyon of Cedar creek and at a few places on the upland.

A delta and alluvial fan at the mouth of Cedar creek represent the amount of material eroded by Cedar creek since the disappearance of the glacier from Quesnel lake basin. The lower part of the lake trends nearly north and south. It is narrow and straight-sided, except for delta protuberances, and is bounded by slopes which are steeper in their lower than in their upper parts. Some of the stream valleys entering the lake are hanging valleys. Such features are generally considered as characteristic of glacially eroded valleys. Cedar creek, for about 1½ miles up from the delta, is a narrow V-shaped rock gorge. It has a steep gradient amounting to over 600 feet in 1½ miles. In places the gorge is 400 feet deep. In its upper part the creek flows in a broad flat-bottomed valley which extends southeast for several miles and is nearly parallel to the lower part of Quesnel lake. The creek divides in the broad valley, one branch heading in a small pond near the southeast side of the valley and the other extending towards Spanish mountain, which lies between the valley and Spanish lake valley on the east. A broad, nearly flat-topped ridge, forming a remnant of the old plain-like surface, lies between the wide upper part of Cedar creek valley and Quesnel lake on the west. The ridge for a mile or so south of Cedar creek is 900 to 1000 feet above Quesnel lake and is about 100 ft. above the lowest part of the broad

* Published by permission of the Director, Geological Survey Canada.



Cedar Creek Placers, Cariboo District, British Columbia

valley of Cedar creek on the east. The ridge is about 1 mile from the lake and rises gradually towards the south where is passes into a high hill near where Quesnel lake turns towards the east. North of Cedar creek the summit ridge is somewhat lower and declines towards the north. Small tributaries of Cedar creek, on one of which the discovery of placer gold was made, have low gradients in their upper and very steep gradients in their lower parts. The upper parts of the tributary valleys are mostly shallow trenches in the drift deposits, and have no visible rock rims. They are post-Glacial or Glacial in origin. The great size of the Cedar creek canyon as compared with the delta, and the presence of glacial drift in places on the sides of the canyon, show that the canyon is only partly post-glacial in origin. Amost all the area is heavily timbered and this, together with the covering of drift which largely conceals the bedrock, renders prospecting difficult. Much of the drift is irregularly deposited and the present surface gives scarcely any evidence of the character of the surface of the bedrock. A hill of drift may overlie a depression in the bedrock or vice-versa, and it is only rarely that a depression in the drift indicates an old channel in the bedrock.

actual summit. Since the original discovery, gold-bearing gravels have been found at a number of points for a distance of about 2000 feet along the course of the supposed channel. Practically all the area has been staked, the placer claims consisting of creek and bench leases having a maximum area of 80 acres. Some of the claims and the location of the gold discoveries are shown on the accompanying map.

Mining Operations

Some prospecting and mining were done on the discovery ground and on adjoining properties in the Autumn of 1921 and during the winter, but little was done in the spring of 1922 partly because of litigation. Owing to faulty location on the part of A. E. Platt who staked the discovery ground, the actual discovery proved, when the claims were surveyed, to be on E G. Stevens' claim. The dispute was finally settled by Stevens retaining the ground and receiving half the gold that had been taken out. In April, 1922, six of the original claim owners, E. G. Stevens, F. McMahon, Mike Sheridan, Dan McCallum and the Grogan bros., pooled their interests and later bonded their claims to the Cedar Creek Mining Company Limited of Van-

Placer Mining, on left bank of Discovery draw, Cedar Creek area, Cariboo, B. C. — The pay gravels are shown in the open cut beneath the fallen stump.

The Discovery

The discovery of placer gold was made by two prospectors, A. E. Platt and John Lynes. It is stated that Lynes was told by John Likely, an old-time prospector of Cariboo now living at Kamloops, that gold had been found in the early days at about the locality where Platt and Lynes made their discovery. Cedar creek itself was mined in the 60's and for many years afterwards but if gold was then known to occur at high levels above the creek the occurrence apparently was not considered to be of importance. The discovery or rediscovery by Platt and Lynes was made in a shallow draw or depression near the head of a small stream flowing into the canyon of Cedar creek from the south and about ½ mile south of Cedar creek. The discovery pit is 910 feet above Quesnel lake and 550 feet above Cedar creek at the point where the tributary creek joins it. It is distant from Cedar creek landing about 1½ miles but is less than a mile in a direct line from the lake. The discovery draw is on the east side of the summit ridge but is only a few feet lower than the

couver of which Mr. F. S. Munson is president and Mr. C. Muir manager. This company began mining operations on July 1 and have employed about 30 men in building a road to bring in machinery, erecting buildings, and in mining and prospecting. Owing to the scarcity of water all the mining has been done with rockers. Two pumps were being brought in during September, the intention being to build storage dams, pump the water up and use it repeatedly for sluicing. Most of the mining by the Cedar Creek Mining Company has been confined to the discovery draw on the Stevens claim but some prospecting has been done on the Sheridan claim. Mining was also carried on during August and September on the Platt claim, in which Mr. R. McCaskill has acquired an interest. Ten men under the direction of Mr. R. N. Campbell were employed and were operating 3 rockers. Here also the water supply was sufficient only for rockers. Prospecting at other places in the area was being carried on by a few individual miners. Numerous prospect pits and shafts, the deepest about 35 feet, have been put down at wide-

ly separated points, but in many places the ground was found to be deep and as soon as the level of the ground water was reached — usually only a few feet from the surface — the prospectors found they could not control the water, even, in some cases, with the aid of a small pump operated by a gasoline engine.

The Placer Deposits

The placer gold occurs in different ways and varies somewhat in character at different places in the area. In the discovery pit only a small thickness of muck and broken and partly disintegrated bedrock overlies the solid bedrock, the gold occuring in the broken bedrock and in crevices in the solid bedrock. The gold is coarse and nuggety and only slightly worn. Gold has been found at various places in the discovery draw for a distance of about 500 feet down stream from the head. It is mostly on, or in, the bedrock. In places there is an overburden of several feet of barren glacial drift, and where the boulder clay is tight on the bedrock the gold is absent. Several test pits sunk in the lower part of the draw failed to show pay gravels, but a shaft sunk on the left bank just below Platt's cabin showed good values, in gravels beneath or in the boulder clay. The gravels are apparently glacial outwash or reworked ancient stream gravels for they are only slightly weathered. The shaft was sunk to a depth of 13 feet and a drive was run from the bottom for 18 feet into the bank. It is stated by Mr. Muir that good prospects were found both in the shaft, except near the surface, and in the drive. The discovery draw ends abruptly about 800 feet above Platt's cabin at a low ridge of drift 20 feet high. Farther up stream, near the Platt - Stevens line, a small marsh occurs, and here also gold has been found in test pits. On the Platt ground the gold occurs at intervals in a shallow draw in the drift for a distance of about 400 feet. The overburden of glacial drift is 6 to 10 feet deep and the pay gravels are 1 to 5 feet thick. Gold was being mined here in September at the rate of 2 to 3 ounces a rocker per day. The gold is finer than on the discovery ground, the pieces averaging about 6 to the cent. Much of the gold is flattened and worn. The pay gravels are yellowish or red because of the presence in them of oxidized clay. They appear to be, in part at least, re-sorted, probably by glacial waters. Finer gold is found in the surface wash farther down the draw and is probably the result of concentration from the drift by Recent streams. Gold has also been found in test pits in a continuation of the draw into the Sheridan ground. A series of small depressions or channels extend along the north side of the trail leading to the pond, in which one branch of Cedar creek heads. They occur along the slope of the southwest side of the broad upper part of Cedar creek valley and are thought by the prospectors to mark the continuation of the gold-bearing channel. It is evident from a study of the map that a broad channel extends southeast at about the same level as that of the known gold occurrences, so that the supposition of the prospectors is not unreasonable. Small prospects are said to have been obtained at one or two places along the supposed course of the channel above the Sheridan claim but apparently the finds so far are not of importance. It cannot be said however that the area has been thoroughly prospected.

The most important mining development of the summer was the discovery of a body of remarkably rich gravels on the left bank of the discovery draw, about 600 feet above Platt's cabin. The pay gravels rest on bedrock and are overlain by 1 to 10 feet of barren glacial drift and muck. They are reddish owing to the presence in them of clay, which is probably derived from weathering of fragments of the country rock included in the gravels. Most of the gravel is angular, but some worn pebbles occur. No glaciated stones were seen in the gravel. The bedrock is fairly smooth but is soft and easily excavated. It is apparently not glaciated. The pay gravels average about 3 feet in thickness, and were exposed by mining operations for a width of 25 feet and shown by test pits to extend for a distance of at least 70 feet. They appear to trend northwest, and into the bank on the west side of the draw. The gold is well distributed through the gravel and little if any occurs on or in the bedrock. The gold is coarse and only slightly worn. The pieces average perhaps 2 or 3 cents in value but nuggets up to $33\frac{1}{4}$ ounces have been found. These gravels were being mined in September. In the 6 days ending September 23, 351 ounces of gold were produced with two rockers from about 15 yards of gravel. The daily output varied from 28 to 101 oz. This was the best week's output of the season up to September 23. The assay value of the gold varies from $17.05 to $17.16. The assay value of the finer gold from the Platt ground varies from $16.99 to $17.21.

The important points to determine in connection with the recent discovery of rich pay gravels are, first whether the gravels are in place and, second, their probable extent. There is little doubt that the gravels are older than the glacial drift. They appeared to the writer to be in place but this may be open to question. If they are in place they indicate the occurrence of an old stream channel at the level at which they lie. The continuation of the channel therefore should be looked for at about the same level. It is possible, however, that the gravels have been moved to some extent by the glacial ice moving across the region, or that they have been formed by the ice ploughing up the broken bedrock in the bed of an old stream. Little can be said regarding the probable extent of the pay gravels until further prospecting has been done, but there is a possibility, as may be seen from an inspection of the accompanying map, that they may extend for a considerable distance, and they give promise of other discoveries when the region is thoroughly prospected.

Progress in the use of asbestos fibres is continuous. A record, necessarily vague, of a recent invention appears in the current number of *Asbestos*, thus:

Several months ago we predicted that some day someone with an inventive brain would discover a use for Amphibole Asbestos which would mean an extensive use of Amphibole and the making of money by the responsible person.

It looks now as tho that day were dawning. Two men at present very little known to the Asbestos trade, have succeeded in perfecting a binding medium which can be used with Amphibole Asbestos and short grades of clay so-lle, to form a plastic material the uses for which are numerous, and will probably increase as further experimentation is made.

At present we prefer not go into the subject in detail, suffice it to say that the material is proposed to be used for interior decoration, the making of solid moulded articles, and also in connection with paper making or board, kieselguhr products and other substances requiring a binding medium.

Recent Mining Activities in Mayo District, Yukon*

by W. E. COCKFIELD

With the decline in production from the placer gold deposits of Yukon, more attention has been paid to lode mining, as the territory is practically dependent upon its mining industry. For some time past Yukon has been attracting attention as a lode mining centre, particularly in the central portion of the territory, where the location of two large companies in the Mayo district gives promise of the establishment of a lode mining camp.

Location and Access

Mayo district may be defined as that part of Stewart River district for which the town of Mayo acts as a base. Mayo is situated on Stewart River 180 miles above its junction with Yukon River. The confluence of the two rivers is 72 miles south of Dawson. Connection

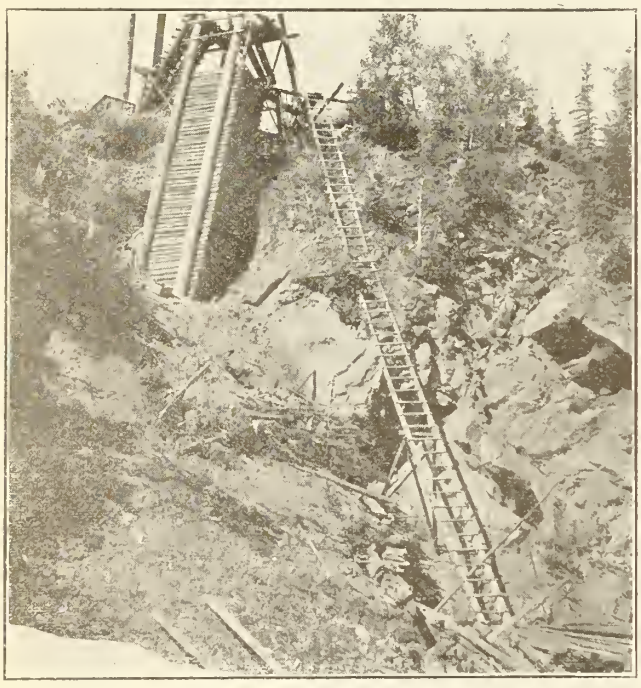


Fig. 1.— Silver King Mine on Galena Creek. The adit forming first level is at the foot of the ladder

with the regular routes between Whitehorse and Dawson is afforded by river steamers during the summer, and by a stage line in the winter. There is also a winter road direct from Dawson to Mayo.

The silver-lead deposits of Mayo district occur along a zone 60 miles or more in length stretching from Mt. Haldane to Beaver river. Recent discoveries show, however, that the limits of this zone are not yet defined, and that it will probably be extended as further work is undertaken.

The deposits are all very much alike in their manner of occurrence. They are veins filling fractures that cut across quartzites, schists, and greenstones, representing the greater part of the bed-rock exposed in the district. These fissures are filled with quartz, siderite, galena, sphalerite, and in some instances tetrahedrite and ruby silver. For a complete description of the veins and various properties the reader is referred to the Summary Report of the Geological Survey for the years 1918 to 1921.

* Published with the permission of the Director of the Geological Survey, Ottawa.

History of The Camp

Although Mayo has been a placer camp since 1898 and the outcroppings of veins of galena were known to the early miners, it appears that the first attempt to mine these veins came about 1912 or 1913 when the Silver King vein, which had been previously staked and subsequently allowed to lapse, was restaked and turned over to two lessees who extracted 59 tons of ore. This ore was shipped to Trail, giving a return of $269 per ton in gold, silver and lead. In 1914 the property changed hands and during the winter of 1914-15 the owners shipped 1180 tons of ore. The property was worked continuously until 1917, when exhaustion of the ore-shoot forced the owners to close down.

In 1918 and 1919 an attempt was made by the Yukon Silver-Lead Mining Co. to mine the deposit at Mt. Haldane. A large amount of development work was done, but failure to find high-grade or shipping ore forced the company to abandon the project after making a shipment of 27 tons of ore for which the smelter returns were 95 ounces of silver and 59% lead.

Recent Development

In the summer of 1919 the deposits on Keno hill were discovered and staked. The Yukon Gold Co. almost immediately took over the original claims. A stampede to the hill followed and within a year upwards of 1500 claims had been staked. A vigorous exploration policy was adopted by the company and in 1920 a subsidiary company, Keno Hill, Ltd., was formed to operate the property. In the winter of 1920-21, 2150 tons of ore assaying 197 ounces of silver and 60% lead were hauled to Mayo to await shipment. At the same time a 100 K. W. steam power plant was erected at Discovery on Duncan Creek, five miles from the mine.

In 1921 Keno Hill Ltd. added to their holdings, acquiring the Friendship group on the western slope of Keno Hill. They erected a second camp on this property and proceeded to prospect it. The company also erected frame buildings on the top of Keno Hill close to their original workings. During the Summer of 1921, two other companies entered the field, the F. W. Bradley interests, and the Slate Creek Mining Co., since organized as the Treadwell Yukon Mining Co. and the Onek Mining Co. respectively. The Treadwell company secured claims adjoining the Friendship group and proceeded to develop the ground by means of two shafts with levels between them. During the winter of 1921

Fig. 2.— First camp of Keno Hill Ltd. The ridge known as Keno Hill in the background.

1922, 3000 tons of ore were shipped. This is expected to run slightly higher in silver than the first shipment.

Progress During 1922

The spring of 1922 found all three companies vigorously prospecting their ground, the main work being done on the original holdings of Keno Hill Ltd., on the Ladue claim of the Treadwell Co., and on the Fisher claim of the Onek Co. A number of individuals were also at work on their claims and some of these have uncovered promising ore bodies. Later in the summer

Fig. 3.—Ore piled at Mayo awaiting shipment.

the Onek Co. closed down and abandoned its options. The other two companies, however, prospected all summer, preparations being made for shipments during the coming winter. Arrangements are being made to handle 7000 tons this winter.

The chief difficulty with which the camp has to contend is lack of cheap transportation. When it is remembered that the ore must be hauled 12 miles to the Stewart River and then transported on river steamers to the mouth of Yukon river and subsequently transferred to ocean going boats for shipment to smelters on the Pacific coast, it cannot be wondered at that only high-grade ore can be mined. All the ore hauled so far has been transported by means of horses and sleds at a cost for the 12 miles of teaming nearly as great as for the rest of the journey. During the coming winter the Treadwell Co. intends to use a tractor in an attempt to reduce their haulage costs.

Promising Field for Prospectors

Outside the actual production of ore, one of the greatest benefits to the camp of the entry of these two companies is the fact that prospecting for lodes has been greatly stimulated and several new finds were reported last summer. Silver-lead ores were found recently in the valley from Keno Hill and also on Beaver river. While both of these are reported as low grade it may be that with further work high-grade ore shoots may be encountered. In any event, these strikes tend to show that there is still much work for the prospector to do in Mayo district.

While nothing has as yet been found that would point to a sustained production for a long period, sufficient development work has been done to guarantee a production of high-grade ore for several years, and a small quantity of milling ore has been blocked out.

CORRESPONDENCE

Speedy Results Predicted

The Editor,
Canadian Mining Journal,

Sir:

With reference to an editorial appearing in your issue of October 20th., 1922, under title of "Porcupine's Need."

The writer was greatly surprised to see such adverse comment on the work of the Ontario Department of Mines published in the columns of your paper. Incidental to this, such a distortion of the truth together with such a caustic undertone has led me to believe that the C. M. J. Bulletin is essential for the true and just presentation of the facts concerning the Mining Industry of the Dominion and C. M. J. Circular No. 3 of 16.10.22 has been duly filled in accordingly.

When a Canadian Mining periodical implies that it takes "seven long years" for the Ontario Department of Mines to present a report it truly seems time for someone to take the defence, feeble though it is in this instance, of a Department that has rendered such signal service to the Industry as had the Ontario Department of Mines. It is pointed out that with limited staff this Department under the able leadership of Dr. Willet G. Miller has kept pace with Ontario's advance in the Mining Industry and has submitted reports and maps, with the exception of some delayed by the recent printer's strike, within a period of less than twelve months from the date of examination. In support of this it might be cited that during the last few months the Department has published reports on the "would be" coal deposits of Sudbury, Ontario within ten days of examination, and on the promising Lightning River Gold Area within thirty days of the completion of the field work. Can you point out an instance of a similar Department rendering such expedient service to the General Public, or to the Mining Industry? It cannot be done. Then why do you editorially belittle the efforts of a Department so efficiently operated to the mutual advantage of the interested public and the Industry?

A plea for assistants for Mr Burrows has been made. It is one-man job. Perhaps the operating companies do not care to give to "the world" intimate particulars relative to their mines, but these are at one man's disposal for correlation and for the purposes of drawing therefrom such deductions as may aid the economic exploitation of untapped promising localities within the camp. The geological re-survey of Porcupine Camp is a one man job, and Mr Burrows [illegible] reported out in your editorial [illegible] of the younger generation of Canadian [illegible] the man for the job, and [illegible] that the implication that [illegible] Department he represents "seven long years" to make findings public is wholly at variance with the performance of the Department. Let's wait and see, but if the general public and the camp [illegible] within a twelve month from the work of the Ontario Department of Mines, then and not until then [illegible] an editorial justifiable is the opinion of [illegible] many others associated with the camp.

Yours, etc.,

[illegible]

Timmins, Ont., November 2nd, 1922.

Vancouver Island Coal

REPORT BY J. D. MACKENZIE AFTER TWO YEARS OF FIELD WORK

"The coal measures of Vancouver Island" is the subject of a report prepared by Dr. J. D. Mackenzie, head of the British Columbia office of the Canadian Geological Survey, who has been engaged in the researches indicated for the past two years. He is of the opinion that the amount of recoverable coal on the Island is considerably below what has been estimated.

He points out that there are three workable coal horizons in the Nanaimo district, and only one in the Comox district, the latter lying over the pre-Cretaceous or barren formation and disturbed by protrusions of the latter in places.

Coal Seams Restricted in Extent

While opinions have differed greatly in the past it was generally supposed that the Lower Wellington, New-Castle and Douglas seams, as occurring in the Nanaimo district, continued for a considerable distance beyond the present known areas. Mr. Mackenzie is of the opinion, however, that they are restricted by contact with pre-Cretaceous formations as they run north towards Cumberland, and that they do not extend far beyond the present workings.

Dr. Mackenzie also emphasizes the importance of the fact that in many submarine mines only 50 per cent. of the coal in the seams is recoverable, due to geological peculiarities, and that seams less than three feet in thickness are of little or no value.

With the experience of two seasons spent in the coal-bearing areas of southern Vancouver Island, and the advantage of extensive diamond-drill prospecting carried on by the coal mining companies of the Nanaimo, Comox and Alberni districts, Dr. Mackenzie has been in a position to make geological calculations with more accuracy than government geologists who have hitherto investigated these coal fields.

Former Geological Investigations

Discovered in 1835 and worked by the Hudson's Bay Company for a time, the coal beds of Vancouver Island were first investigated by the Dominion Geological Survey in 1871, when James Richardson, examining the coal-bearing rocks from Comox to the southern gulf islands, spent parts of five seasons in the field. In 1911 Dr. C. H. Clapp studied the Nanaimo field, and his memoir has since been the basis for many operations there. Dr. Mackenzie has been entrusted with the task of bringing government reports on this area up to date, and he has since carried on extensive research.

Geology of the Coal Measures

"Conditions on the island are those to which geologists give the name of 'progressive overlap,' the significance of which is considerable in regard to the coal resources of Vancouver Island.

"Because of this overlap the coal-bearing horizons of the Nanaimo area are not found north of Nanoose, and for some reason not wholly understood the coal-bearing horizon of the Cumberland area does not contain coal south of Deep Bay.

"Another point the study of these coal measures has brought out is that the coal horizon does not always contain workable coal seams, and that in certain areas seams are so distrubed by deformation that considerable areas have been rendered unworkable.

"After the accumulation of strata forming the northern series, they were folded by earth movements, and the same movements caused an uplift which has subjected these rocks to the influence of erosion. For this reason scores of cubic miles of sediments containing an incalculably large tonnage of coal have been lost by being swept away, and now lie finely distributed over the bottom of the Straits of Georgia.

"Present areas underlain by the Nanaimo series are thus but remnants of a former, much more extensive covering of sedimentary rocks.

"Three principal areas along the southeastern coast of Vancouver Island now underlain by rocks of the Nanaimo series are the Comox area, the Nanaimo area (including the gulf islands), and the Cowichan area. A fourth area underlies the Alberni district, in the interior of the island.

"Coal has been found in workable thickness in portions of Comox and Nanaimo areas, but no workable seams are known in the Cowichan or Alberni areas.

Mineable Coal Formerly Over-estimated

"I have already pointed out that there are only three workable coal horizons in the whole of the 7,000 to 10,000 feet of the Nanaimo series, and that the presence of sedimentary rocks of upper Cretaceous age is of itself by no means a guarantee of the presence of workable coal.

"There are always losses in the mining of coal on Vancouver Island. A certain amount of coal is left in pillars and in seams that are too thin to allow it to be recovered. Some areas are so broken by faults that economical extraction is impossible. In others knobs of the underlying, barren, pre-Cretaceous rocks project through certain portions of the seam, interfering with ventilation as well as with the placing of haulage roads. Considerable areas of coal may be lost by mine fires, excessive gas, water or other causes.

"It is no exaggeration to state that over considerable areas of Vancouver Island there are mines in which scarcely 50 per cent. of the coal actually in the ground has been extracted, because of conditions quite beyond the control of the operators.

"When all these modifying circumstances are taken into consideration it is clear that a figure far short of the 1,340,000,000 tons previously estimated would be nearer the actual coal recoverable from the Nanaimo area.

"A careful examination of the data given by scientists who examined the field in the past shows that the popular interpretation of their statements in relation to the amount of coal recoverable on Southern Vancouver Island is not warranted, but nevertheless the impression of the unlimited nature of the coal of Vancouver Island persists."

Dr. Mackenzie stated that a great amount of prospecting has yet to be done in the Island coal fields. There is, he states, a large area between Courtenay and Campbell River that will require expensive and detailed prospecting.

Letters From Porcupine--I

THE SECOND PHASE

Porcupine is no longer a three-mines camp. Long, perhaps too long, the lesser mines and the undeveloped propects have lain under the shadow of the mighty trinity—Hollinger, McIntyre, and Dome. It has been discouraging both to the small operator and to the claim owner to know that the standards of the camp are set by these three great properties. The trinity, unwittingly, has been a let and a hindrance to the expansion of Porcupine. The public conception of the camp embraces only the three mines. This has been one cause of deferred growth. But there is another related and underlying cause that requires mention.

To protect myself against the imputation of disguised or unfair criticism, let me say at the outset that what I now write has no reference to the Ontario Department of Mines. With this said I feel free to proceed.

Whilst the popular idea that Porcupine consists of three mines has been and continues to be a drawback, it is certain that another cause has deterred mining men themselves from going on boldly with the development of the region. Without hesitation I ascribe the lack of initiative hitherto displayed to the general adoption of a curiously rigid geological formula.

The acceptance of hard and fast geological ideas has retarded the growth of almost every famous mining camp on this continent. A conventional geological theory, once accepted, is hard indeed to dislodge. In its very nature it is restrictive and exclusive. Its exponents resent anything that tends to weaken it. Therefore, any mining property that cannot live up to its exact and exacting specifications is out of the running.

All theories are fallible. At best they are close approximations to the truth. When all facts are known a theory ceases to be a theory. No one will claim that all the facts about the Porcupine ore deposits are known. What is needed, then, is the judiciously open mind. Geological prejudice has had the effect of literally crippling many promising Porcupine prospects. It is gratifying, therefore, to observe the increasing activity of the iconoclast and of the man who follows his own hunch. It is not that the science of geology is being discredited, but that those who arrogate to themselves the right to force geological dogma down unwilling throats are losing ground.

* * *

In discussing this condition with a widely travelled English mining man, he dwelt upon the strong contrast between Porcupine's retarded development, and the rate at which progress would have been made if Porcupine had been discovered in South Africa or Australia. There is assuredly something more than climate to explain away.

* * *

It has been the fashion to look askance upon properties situated outside certain arbitrarily drawn lines. Strangely enough these lines correspond closely to certain township survey lines. Here the home-grown Porcupine fetish, or shibboleth (both words will do) has played its part. In truth and actuality that fetish was overthrown many moons ago; but the public does not know this. Two recent incidents, and many more might be cited, tend to show how completely wrong are current geological prejudices. Of these incidents the first was the discovery of spectacular ore on the Paymaster, in Deloro township, where, also, a good body of milling ore is being developed. The second, of which I have have not yet seen any public announcement, was the discovery on the Rochester of a healthy vein, carrying visible gold, in a cross-cut south under Miller Lake. This is an example of flouting the fetish in its inner sanctuary.

* * *

To those who knew Porcupine in the brisk days when "Ma" Potts was Queen-regnant of Pottsville and all its messuages and purlieus, and "Pa" was the Prince-consort, wholly destitute of executive authority, Timmins and South Porcupine seem obtrusively modern. Up-to-the-minute shops, comfortable hotels, motor cars, radio stations, daily train service, telephone connection with the outside world (beyond New York indeed), bring everything to the commonplace level of city life.

* * *

The intense competition between the representatives of mining machinery firms has many interesting side lights. In the old days "intense competition" would have been too mild a word; what went on then was the bitterest kind of rivalry. Representatives were chosen for their ability to bluff and bull-doze. "Secret" commissions were (it was whispered) the order of the day.

To day the scene has changed. Only men of the highest qualifications, men who know their business in every practical and professional detail and who are able to demonstrate their knowledge, are selected to undertake the frightful task of making a pig-headed mine manager see reason. Tact, forbearance, both only to be acquired by hard experience, are necessary to the task.

In Timmins, at the present time, there is an unusually large number of just such men. To me their zeal and patience are abiding sources of wonder. The mining practice of Porcupine demands the highest quality of equipment. In the matter of hammer drills, for instances, cheap air and high speed of work call for drills that must stand more punishment than would be given anywhere else. This fact has necessitated numberless costly changes in design and in material of construction. Doggedly, and regardless of expense, manufacturers have gone about making trial after trial, until, I suppose the hammer drill, as used in Porcupine, is gradually approaching perfection. It is certainly nearer perfection than it would have been if the mine superintendents had not been such a hard boiled bunch of rock eaters!

* * *

Neither Timmins nor South Porcupine is yet immune from the risk of total obliteration by fire—bush fire. It was suggested to me by a friend who knows much more about the country than I do, that at a cost of about fifty dollars per acre, a zone of three miles width surrounding the two towns could be cleared completely and the menace of fire once for all removed. Much of this land could be seeded down with clover, which I am informed will

grow luxuriantly in that soil. Even if this procedure were twice as costly, it would not be too high a premium to pay for insurance of life and property in Canada's greatest mining camp. It strikes me that the initiative lies with the Provincial Government.

* * *

The presence in Timmins of scouts looking round for properties for established mining companies is nothing new. Established companies are notoriously hard dealers. The chances are always 100 to 1 that they will not do business. It is good, therefore, to know that English engineers are on the scene, looking round quietly for legitimate ventures, not for the "sure thing" that Canadian scouts seem to expect to acquire for next to nothing.

God forbid that we should witness a boom in Porcupine. It is not needed. The profiteers of the stock exchanges would be sole beneficiaries. But it is most manifest that Porcupine has cast off the swadding clothes of infancy. They haven't fitted well for a long time. In fact the assumption of the toga may follow (unconformably) the casting off of infantile integuments.

J. C. MURRAY

News and Comments

BY ALEXANDER GRAY

The Banker Makes Acknowledgement

It is almost sensational to have the Royal Bank of Canada—one of the greatest credit institutions—in its November bulletin remark of Northern Ontario mineral developments in this strain:

> "During the past two years, the mineral output of the Dominion was valued at $237,400,000 and $172,300,000 respectively. Toward these totals, the largest contribution was made by the gold and silver mines of Northern Ontario, which, during recent months, have shown greatly increased activity. It would be easy to underestimate the importance of these rapidly developing industries in the commercial life of the province, and, in fact, of the entire country.
>
> "During the month of August, gold from the Kirkland and Porcupine districts amounted in value to approximately $1,820,000. The production of gold for the first half of 1922 shows a large increase over that of any similar period, and gives promise of an output exceeding $20,000,000 in value, for the year, in comparison with $14,624,085 for 1921."

Those are handsome admissions, handsomely made. Mineral industries are conceded to be a factor in the economic existence of the Dominion. Banks have a rule that precious metal securities, however strongly "backed," cannot be entertained as collateral. They are prepared to lend on behalf of coal and iron mines, but the precious metals are altogether "too utterly too-too!" To a certainty, it would be more than an indiscretion for banks to carry the generality of script, even if the discounting and interest were usurious; yet there is satisfaction in having the Royal Bank pass the bon-bon dish. Sir Edmund Walker and his Adjutant, Logan, have devoted space and praise to mineral industries. Indeed, more than one bank has lost very useful accounts because they declined to concede what the Royal Bank admits. Of course it might be necessary for banks to retain a technical staff; but that would be no more than now obtains in the United States, where a Mining Engineer is an essential part of administration. At any rate, the Royal Bank has thrown this picture upon the screen.

> "The production of silver also has shown a very rapid development during recent months, in the mining listricts of Northern Ontario. During August 850,000 ounces were produced in the Cobalt, South Lorrain and Gowganda districts. The production of silver for the first half of the year shows an increase in volume of 720,000 ounces, over the same period a year ago."

Nor is that all the Royal Bank has to say. Its November bulletin was the more comprehensive in its appreciation of mineral industries, by incorporating this:

> "Certain of the mineral products of Canada are of special interest, in view of the large percentage of the world's supply of raw material which Canada possesses. Nickel and Asbestos are virtually Canadian monopolies. Of the former, Ontario mines produce more than 80 per cent. of the world's output, and, of the latter, the Province of Quebec produces the same percentage of the world's total."

All the more reason why more banking utterances should bear upon these matters. The banker has the say, and properly so. He may not understand that the Quebec Asbestos Industry has rivals. There are competitive metals in the Nickel field, and slow markets for Nickel and its alloys. Therefore, bankers and politicians and statesmen—if you will—can be helpful—if they will.

"Tom" Moore's Diatribe

As a Canadian delegate to the International Labor Congress, "Tom" Moore (who lacks the poetry of his namesake) has been spouting in London about "the hardships of mining and the impoverished conditions prevailing among miners in Northern Ontario." He warns "Cousin Jacks" not to come here for $3 a day. Moore speaks as a "mucker." He is unskilled as a miner(with other than his mouth) and that will be understood by Cornishmen and others familiar with the wage schedules obtaining in Ontario. Such as he would cripple industry. Claptrap of this sort is what makes it all the more surprising why willing-to-works (at excellent wages) are stopped by Ottawa regulations.

Why "Guarantees"?

The London correspondent of the "Montreal Gazette" voices the resentment of the backers of the proposed British Columbia Steel Industry, who met with opposition in their endeavors to have the Imperial Government guarantee a debenture issue that would be a first charge on the undertaking. He appears to join in placing the blame upon "Eastern Canadian Capita-

lists," who also, it seems, "crabbed" the Humber River hydro-electric scheme in Newfoundland, although "British paper-makers" threw a few monkey-wrenches at the Newfoundland project. Undoubtedly we would all congratulate promoters of anything, anywhere, if they could have their legitimate and praiseworthy plans lubricated by any government; but those not so favored naturally rise to remark that they should have their helping while the fiscal "oats" are available. We have had a Nickel experience of this sort!

The Curtain for Knight Central

At first blush it may be incomprehensible why the cables announced the closing down of the Knight Central Mine at the Witwatersrand. The exhaustion of a mine is not considered a universal event. Ordinarily it would occasion local regret and few flowers. But the name of "Jim" Knight is emblazoned upon the Rand escutcheon along with those of John Charlton, Simmer, Robinson, Ferreira, Bantjes, and the others who staked early. "Jim" Knight, moreover, bequeathed a daughter to Canada in the person of Mrs. Machin, wife of the persistent patron of the Mikado-Sultana section of Ontario. Several "Knights" were incorporated on the near east Rand. "Jim" got his share of the perquisites.

Knight Central was formed twenty-seven years ago; shaft-sinking began in 1896, and the main reef was struck in 1899 at approximately 2,000 feet. The cash capital altogether invested in the property to date amounted to about £1,100,000. The Boer War intervened. Since milling began in 1909, nearly 3,900,000 tons were crushed for a gold yield of about £4,100,000 at a cost of almost £1,050,000. The working profit, interest and sundry additional revenue totalled some £600,000, so that did not enrich shareholders in general. There remains a small tonnage to be salvaged. Anyhow "Jim" Knight and the "Knights" have their place in history; and those who knew him might not have known, were it not for the cables, that Knight Central has "passed in its checks."

"Toronto Telegram" Perceptage

Commenting on the glutted state of the Toronto "Mining" stock market, the *Telegram* fears acute indigestion before Spring and therefore advises all that one in three hundred "prospects" have a chance, so no one should put money into such ventures without being able to lose it. How the calculation was arrived at is the business of the *Telegram*. Undoubtedly the persistence of the Appeals to the public for loose change amounting to a great deal in the aggregate has left the speculative position somewhat waterlogged. That however, does not affect the fact that the "also rans" in any competition never get in the money. So long as newspapers give space to the racy, tag and bob-tail stuff and do not sometimes credit by censoring reckless statements, the chances are as one to three hundred. But advertising demonstrates have established that ratio—not the mineral deposits.

Dome Mines Recapitalization

Dome Mines shares of no par value, for each share of $5 parity, as what is announced from New York. As the outstanding capital is 176,667 shares that are valued in the market at $21,920,682, or so, it is quite obvious the price had become "unwieldy". Under the new arrangement the redemption of capital hardly will proceed so rapidly. Incidentally, Mr. Howard Pollon resigned from the directorate. He may not be the most diplomatic conversationalist, but he has the faculty of "speaking his piece"—and that is an asset. As the partner of Herbert Poirier, the firm of Pollon and Poirier has won a permanent place in the North Country. They are mining engineers who rendered distinctive service without sacrificing popularity—which is "saying something" in mining. It is the sincere wish of those who have faith in the Northland that Messrs. Pollon and Poirier will retain that technical relationship, which will be helpful as it has been profitable.

Scouting British Columbia

It is informative to have it from reliable sources that Butte interests have had formidable parties in the Pacific Coast country during the past Summer. As many as seventeen are said to have been giving British Columbia, Alaska and the Yukon, the "once over". Entry of the Guggenheims and others into Portland Canal and the Mayo district and the success attending Premier Mine operations are largely responsible. Concededly the localities call for capital. In the near future undoubtedly there will be more capital available, notwithstanding the factor of inaccessibility. When it is necessary to resort to early Mexican selective mining, as is the case in the Mayo district, nothing but very high grade being commercially profitable, it calls for no elaboration to make it clear that the past ten years have been ideal for prospectors. The race goes to the strong. Experienced operators are getting the best there is, and leaving the other until economies are attainable. The Premier and affiliated companies are establishing their section. Messrs. Thomson & Doheny of Montreal have had a successful year in Alaska, and, if they read aright the signs, next year will be better. Mr. W. P. Alderson, who has just returned from there, reports in the most optimistic way of the country, despite operating handicaps. And as for creature comforts, Mr. Alderson lived on moose, caribou, venison, mountain sheep, partridge, grouse, salmon and trout until he dislikes to revert to common-or-garden fare. When one steamer on the Yukon was delayed for three hours by caribou the variety outweigh adversities. Besides, Mr. Alderson is venomous as well as voracious, when it comes to game and game hunting.

Development work is now under way on asbestos claims in British Columbia located on Mount Sproatt, 24 miles south of Revelstoke. These claims are located at an elevation of 1,200 feet above sea level and about 2,800 feet above the nearest railway. The location of the claims, necessitating the expenditure of a considerable amount of capital to bring them to a profitable producing stage, is said to be the only obstacle to their rapid development.

The Yukon's gold output [illegible] million and three-quarter ounces. Dredging [illegible] along the creeks beyond the usual period [illegible] unusually mild autumn and the gold production [illegible] increased correspondingly. Hydraulic mining [illegible] were shut down a few days [illegible] still throughout the gold creeks. The [illegible] from Mayo dropped to date [illegible]

Preservative Treatment of Mine Timber

BY TREATMENT THE AVERAGE LIFE OF TIMBERS UNDERGROUND, NOT SUBJECT TO WEAR, IS INCREASED FROM SIX OR EIGHT YEARS TO LONGER THAN THE LIFE OF THE AVERAGE PROFITABLE MINE

Preservation of mine timbers by treatment, first as a conservation measure necessitated by the rapidly decreasing supply available on the North American continent due to the enormous and ever increasing consumption, second in the interests of economy by treating against decay, is urged by R. R. Hornor in his report of an investigation instituted under the auspices of the U. S. Bureau of Mines.

Mine timbers, the report states, are destroyed by four principal agents—decay, insects, fire and mechanical abrasion. Of these, decay and insect attack are by far the most important. The amount of mine timber destroyed by these different agencies varies greatly with the conditions in the mines, and depends largely upon the character of the deposit, and method employed in mining it. In general more than 50 per cent of the timber used in the mines is destroyed by decay and insect attack, but perhaps not more than 15 per cent of the total is subject to replacement, that is, where the working place will be kept open longer than the natural life of the timber.

Timber conservation may be accomplished in part by the better selection, preparation and storage of timber intended for mine consumption, but the most effective means is by treating the timber, to prevent decay, with some standard preservative before it is placed in the mine. It is needless to point out that only those timbers should be treated that will be used in working places which are to be maintained for a period of years sufficiently in excess of the natural life of the timber to warrant the use of treated timber. Neither should treated timber be nesd in places where it would be subjected to destruction by crushing rather than by decay.

It is estimated that on an average possibly 85 per cent of all the timber employed annually in the mines of the North American continent is used in working places of only temporary nature, such as rooms in coal mines and stopes in metal mines that will shortly be worked out and abandoned. Much of this timber is destroyed by crushing or covered up by waste rock and is of no further service. Even where subjected to decay, its natural life is usually greater than its mechanical life, therefore preservative treatment would not be justified. The only practical means of reducing the quantity of timber used in this manner would be to either modify the existing system of mining or adopt an entirely different system wherein less timber is required.

Average Life Three Years

Of the enormous total of approximately 293,000,000 cubic feet of timber consumed annually in American mines it may be safely estimated that an average of 15 per cent. or 43,950,000 cubic ft., is used in underground haulage ways, airways, and other openings of a more or less permanent character where the timber is largely destroyed by decay. Experience has shown that the average life of mine timber in permanent openings, where it is not subject to crushing, is about 3 years, but often under conditions unusually favorable to decay the life will not exceed one year. On the assumption that the average mine shaft, tunnel drift, and gangway, will be in service for a period of 12 years, the timber supports will be renewed at least three times, and under some conditions five to ten times. If the minimum figure is taken the quantity of timber consumed during the 12-year period is 175,800,000 cubic feet, of which 131,850,000 cubic feet might have been saved had the original timbers been given a preservative treatment. If the average cost of the timber be taken at 25 cents per cubic foot, the saving in timber alone would $32,962,500. The labor cost in replacing would be equal to and in many instances much more than the cost of the timber. It is obvious, therefore, that by treating timber to prolong its life the annual saving in cost of labor and timber will be large.

In the foregoing estimate of the annual consumption and value of mine timber no account was taken of the relatively large quantity of timber used in surface construction. Unfortunately, no data are available upon which to base even an approximate estimate of the quantity of timber thus used. Obviously, however, the quantity is large as may be appreciated by citing some of its many uses.

The principal surface structures built wholly or in part of wood are head-frames, shaft houses, breakers, tipples, tramways, ore bins, coal bunkers, trestles, flumes, concentrating mills, stamp mills and mine buildings- timber framing and carpenter shops, blacksmith shops, machine shops, power houses, change houses, and supply houses. In addition, an important amount of lumber and dimension timber is used in miscellaneous mine and mill equipment such as mine cars and trucks, tanks, launders, conduits, concentrating tables, jigs, flotation machines, classifiers, battery blocks, foundation timbers, etc. These structures and equipment require constant repairs and replacements, of which perhaps 80 per cent. or more, is caused by decay and could be largely avoided if the original timber were given a preservative treatment.

Treatment Effects Important Saving

The average life of untreated wooden surface structures is placed at 10 to 12 years; but the average life of timber entering into mine and mill equipment subjected to replacement from decay is probably not over 6 to 8 years. Assuming the average period of usefulness of all kinds of mine construction is 20 years, then the timber subjected to decay will require replacement at least once during its period of service in the case of surface structures, and twice in case of mine and mill equipment

With proper preservative treatment of the original timber entering into this construction, it would be made to last throughout the entire period of ser-

vice, thus effecting an important saving in the cost of material and labor.

To determine the advisability and economy of treating underground timber, also timber used in surface structures and equipment, Barth formulated a rule which is substantially as follows: Timber that is permanent in character and which is not exposed to destruction by mechanical wear or crushing before the expiration of its natural life, or the usefulness of which does not cease before the advantages of chemical preservation can be realized, should be treated.

Book Reviews

A. S. T. M. TENTATIVE STANDARDS—1922.—American Society for Testing Materials—1315 Spruce St., Philadelphia, Pa. paper $7.00, cloth, $8.00. pp. 774.

This annual volume, which is of increasing importance to the engineers of this continent, is just off the press. The volume for 1922 contains 163 Tentative Standards, as follows:—

18	relating to	Steel, Wrought and Cast Iron.
13	"	Non Ferrous Metals.
27	"	Cement, Lime, Gypsum and Clay Products.
15	"	Preservative Coatings.
13	"	Petroleum Products and Lubricants.
35	"	Road Materials.
4	"	Coal and Coke.
9	"	Waterproofing.
5	"	Insulating Materials.
4	"	Shipping Containers.
12	"	Rubber Products.
4	"	Textile Materials.
4	"	Miscellaneous.

The term "Tentative Standard" is used to distinguish a proposed standard, issued for general criticism and subject to amendment for a period of two years or more.

The A. S. T. M. is performing a notable service for both the United States and Canada. Our own Canadian society, composed likewise of members doing voluntary service for the general good, can be coupled with the American organization in our hearty commendation and appreciation of their good work.

BELT CONVEYORS AND BELT ELEVATORS—by Frederic V. Hetzel—John Wiley & Sons, New York. Renouf Publishing Co., Montreal—333 pages, illustrated—$5.00 post paid.

"This is intended to be a practical book. It is not a mere restatement of what already appears in trade advertisements, nor does it contain descriptions of installations of conveying and elevating machinery. It aims rather to explain principles and the reasons for doing things." So says the author in the preface, of this eminently practical treatise. It not only explains in great detail the principles concerned, but presents the means of applying them. The 58 tables of various sorts interspersed throughout the text illustrate this fact, giving the strength and weights of materials, standard comparative dimensions, horse-power and capacity, standard parts, calculation of stresses, etc.

The miner and metallurgist usually have a direct concern, and often a vital concern with belt conveyors and elevators. Few mills, or even crushing plants, can do without them. Those who wish to acquire a thorough knowledge of such mechanisms can do so conveniently and at the expense of a minimum of effort with the aid of Mr. Hetzel's book.

CEMENTS, LIMES AND PLASTERS—by Edwin C. Eckel—Second edition 1922—John Wiley & Sons, New York; Renouf Publishing Co., Montreal—670 pages, illustrated.—$6.50, post paid.

Mr. Eckel is one of the most lucid and thorough of contemporary technical writers. Mining engineers who have read his "*Iron Ores: their Occurrence, Valuation and Control*", 1914 and "*Coal Iron and War: a Study in Industrialism, Past and Future*", know already the masterly style in which he is accustomed to treat his subject. The present work, extensively revised from the original edition of 1905, is compendious in its scope and thorough in its treatment.

"Of all the non-metallic structural materials in use by the engineer, the most important at the present time are those included under the head of Cementing Materials, using that term in its broadest sense to include not only the hydraulic cements proper, but the lime, plasters and allied materials." This statement from the preface provides the thesis. These are treated in succession gypsum, lime, magnesia, hydraulic limes, natural cements, Portland cement and Puzzolan cements, the last being made mainly, on this continent, from blast furnace slag. The constitution, properties, geological occurrence and process of manufacture of each of these is described in succession. As the scope of the work is so widely inclusive, no one subject can be treated exhaustively in detail; hence very complete bibliographical references are given at the end of each principal section. As in natural and logical, the discussion of Portland cement occupies a large part of the volume.

Though the book is concerned principally with the industry in the United States, Canada comes in for a fair share of notice, particularly in the discussion of deposits of gypsum and magnesite, as these minerals are at present mined in Canada chiefly for export to the United States.

This work is, no doubt, to a great extent technical in interest the specialist in the lines it treats. It has, however, a wider usefulness among those who desire a general and accurate knowledge of the subject, and this new edition will prolong its usefulness for a period of years.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

An Offer to Buy—Kirkland Lake Proprietary directors have circularized the shareholders, advising them that they have been approached by an influential group of Americans, who have important holdings in Northern Ontario, with a view to the consolidation of interests. No details are given, but the directors wish to be advised of the general attitude of the shareholders in order to decide whether or not to proceed with negotiations. It is generally understood that the group mentioned are those behind the Continental Mines, Limited. The latter company has large holdings in Kirkland adjoining and lying to the east of the Tough-Oakes. An amalgamation with the Proprietary holdings would give them a substantial mining plant and mill and enable them to get on a producing basis immediately, pending the development of the large area of unexplored ground that the Continental now owns. The directors advise that the recent discovery at the Tough-Oakes has been so satisfactory that there seems to be a reasonbale assurance of continuous dividends being paid. On the new vein recently discovered fifty feet of driving has shown an average of $28.80 over 56 inches. Under these circumstances the directors hesitate to assume the responsibility for negotiating without a definite indication of the opinion of the shareholders.

Power on Again—Matabitchouan power was turned on Kirkland Lake on November 3rd, and mills in the camp have again started operations.

Milling at Ontario-Kirkland—Directors of the Montreal-Ontario announce that milling operations will be started immediately. The above company consists of an amalgamation of the Ontario-Kirkland and the Montreal-Kirkland. The Ontario-Kirkland is developed to a depth of 450 feet and is equipped with a mill having a daily capacity of between 150 and 200 tons. It was generally understood that ore reserves were substantial and a grade sufficient to permit of continuous operation. When the mill was started, however, it was found that the ore only averaged about $2.50 per ton. Being rather short of cash, it was not long before the company was forced to close down. Subsequently it was amalgamated with the Montreal-Kirkland, which undertook to assume the outstanding liabilities. A new manager has recently been appointed to the property, and he states that the average value of the main vein was approximately $9.00 per ton, and that this value has been proved over several sections on the 450-foot level. He states, however, that in the former stoping operations, dilution was so great that it accounts for the low grade that went to the mill. He states that the mine is capable of producing 100 tons per day of $8.00 ore from the 450-foot level, from which it is estimated that a profit of approximately $2.00 a ton can be made. The old Ontario-Kirkland was the one big disappointment of the Kirkland camp, and while it is very doubtful if it can "stage a come-back", such an eventuality would do more than anything else in greatly increasing development along the south "break" upon which the property is situated.

Bidgood—The Bidgood has cut its vein on the 600-foot level, but it is understood that the values are low. It is not expected, however, that the best part of the vein will be developed before another month.

Stellar—Nipissing has started a third diamond-drill hole on the Stellar claim in Kirkland. The first two holes cut several fractures, but it is understood that the values were low.

Good Year for Coniagas—Coniagas' fiscal year ended October 31st, and it is stated that results were quite satisfactory, although the profits will be lower than for the preceding year. While the production in ounces was approximately the same, the tonnage treated was greater and the average silver content was lower. The Coniagas has rebuilt the mining plant on the Ruby, destroyed in the recent big fire, and has resumed underground work there.

Prospective Offer for Peterson Lake—Peterson Lake directors aore sending out circulars to shareholders asking them to join with the directors in selling control to a large Cobalt company, at 25 cents a share. It is understood that this is in order to meet the requirements of the prospective purchasers and that negotiations are by no means concluded. The President of the Peterson Lake states that he expects the results of the October operations on tailing retreatment will show a good profit.

Farah Prospect—The Mining Corporation has taken a lease on the Farah property in Cobalt, and has started a small gang to work.

Abitibi—The Abitibi Gold Mines will proceed at once with the development of its claims in Lightning River. A plant will be taken as soon as the winter roads are in shape, and a shaft sunk to a depth of 100 feet. According to the recent geological report of Mr. Knight, the property has an encouraging surface showing.

Lightning River—It is understood that the Lightning River Gold Mines has disposed of a large block of treasury stock to Toronto interests, and that when this money is received, underground development work will be proceeded with immediately.

Miners from England—110 Cornish miners have arrived in Porcupine to work at the Hollinger Gold Mines. There are a large number of idle miners in Cornwall and picked men are being brought out to fill the shortage which is expected to arise in the gold mines of Northern Ontario. The bringing in of these men does not appear to meet with favor from Mr. Tom Moore, President of the Canadian Trades and Labor Congress. He is credited with having made a number of ridiculous remarks regarding rate of wages and conditions of employment, and in one of the labor papers gives an interview in which he states that at the present time unemployment is rife and that it is a question if any of the men being brought in would get more than $2.50 a day. The facts are, however, that there is plenty of employment for good men in the mines, and that the minimum scale of wages in Porcupine in $4.24 a day. Miners receive $4.80 a day, and as a good deal of the work is done on contract, a great many of them will be able to make considerably more than this.

NOVA SCOTIA

RECORD AT STEEL PLANT—General Superintendent Bischoff of the steel works at Sydney complimented the heads of the departments the other day on the new high records during the month of October. They were the highest in the history of the works. Mr. Bischoff took occasion to turn the attention of his assistants to the accident list and asked them to begin a campaign for a lower accident rate. He reviewed the work of the safety department, and stated the number of accidents in September and the cost to the Company for compensation claims during the year, which were very large. He pointed out that while twenty-five per cent. of the accidents can be prevented by safety guards, the other seventy-five per cent. could only be prevented by education.

OUTLOOK FOR WINTER TRADE—President Roy Wolvin and vice-president D. H. MacDougall spent several days in the Sydney and Glace Bay districts inspecting the steel and coal plants. While the President gave out very little for publication, we know that he was optimistic on the coal and steel outlook. Indications point to some success by the President in his effort toward financing in the United States, and it is well understood that the British Empire Steel Corporation can take care of all necessary development to increase both the steel and coal outputs, especially the latter. One thing is assured, and that is a busy coal trade during the coming winter.

MORE PIG IRON—A third blast furnace will be blown in at Sydney shortly and probably a fourth about the begining of the year.

STEEL DEMONSTRATOR—Mr. G. Wheeler, of Warren, Pa., a well known scientific steel demostrator, visited the Sydney plant and made tests of rail steel in the matter of hardening and tempering. The demonstrations were of a varied nature and showed the possibility of working up into various steels the rail steel now produced by the company.

BRITISH COLUMBIA

SILVER NEAR NELSON—High grade silver ore is reported to have been found on Canyon Creek, near Nelson. A sample, states the owner, James Cummerford, gave returns equal to $2,000 a ton in silver and several dollars in gold. About five tons of this ore is ready for shipment. The property is situated at an altitude of 8,000 feet.

SILVERSMITH—Reports just issued for the benefit of stockholders state that the Silversmith Mine, Sandon, for the period of June 1st to Sept. 30th of this year made a net profit of $83,350.57. There have been many improvements to the plant and much development in connection with the property. The flotation plant has been perfected and a 200 h.p. Diesel engine is being installed as an auxiliary unit to furnish additional power during the winter months. A heating plant for the mill and adjacent buildings has been installed as well as an American filter and zinc buns. There are, besides, a machine and blacksmith shop as well as an assay office and additional settling tanks. One hundred men are employed. The Company milled 3149 tons of ore assaying 21.75 ozs silver, 8.6% lead and 6.2% zinc during the month of June. Production averaged about the same over the succeeding months up to and including September. It is stated that accurate figures cannot now be given as to the number of tons of zinc concentrate on hand, but the tonnage is placed roughly at 2000 which is additional to the output for the four months referred to. The value of the crude lead and zinc concentrates after deduction of freight and treatment costs, it is thought, should amount to $272,338.29. From this, however, must be deducted operating expenses, royalty to the Minerals Separation North American Corporation on flotation concentrate; also a sum for depletion and depreciation. Additional reserves are being opened up. The report concludes with the statement that with a profit of over $83,000 in the period under review, shareholders may now look forward to quarterly dividends. Oscar V. White is the manager of the property.

CARIBOO—Thomas Drummond has commenced placer mining operations on Hemlock Creek, east of Cedar Creek. He installed a flume and although water from this source was available for but a few days, was able to clean up, it is stated, about $2000. Hydraulic work will be carried on more extensively next season.

GEOLOGIST REPORTS DISCOVERIES—Dr. C. R. Cairnes, of the Canadian Geological Survey, has returned after spending the summer in the Yale and Similkameen Mining Districts. He states that there are several promising low-grade copper and gold properties and a number of higher grade silver-lead prospects in that section. Among mining properties examined was that of Summit Camp at the head of the Tulameen River which is an old mine on which some development has been done. Very little ore has been shipped, however, owing to transportation difficulties. With the improvement of the road from Tulameen Village on the one side and Coquihalla Valley on the other there is every chance of the opening of properties of considerable importance. Dr. Cairnes says that there are a number of properties in the vicinity of the Nickel Plate mine, the ore of which is of much the same character as that of the latter and which may be developed in the near future.

PEACE RIVER DRILLING BRINGS GAS—Recent reports from the British Columbia section of the Peace River country indicate that three companies have been drilling for oil during the past season. The Imperial Oil Co. is still at work in the vicinity of the town of Rolla and is down about 2700 feet. At this point there is a strong flow of gas which now has been piped off. Accidents, too, have hindered progress. The drill, however, has passed through the great shale beds and now is said to be working in the sandstone formation. The Imperial Oil Company's well is on the Alberta side of the Provincial Boundary but on the British Columbia side the Ponce Coupe Oil Co. has been putting in a test hole with a diamond drill and had reached a depth of 1600 feet about a month ago. Another concern has been diamond drilling on the Alberta side but has not got down more than 150 feet.

C. I. M. & M. MEETING—Quite a lengthy and interesting program has been prepared for the annual meeting of the Western Division of the Canadian Institute of Mining & Metallurgy. Among well known mining men who have been specially invited and are expected to attend are T. A. Richard, formerly of San Francesco and now prominently associated with the *Engineering and Mining Journal Press*, New York; R. V. Norris of Wilkes-Barre, Philadelphia; J. R. Findlay of New York; R. C. Allen of Cleveland; L. C. Graton of Cambridge, Mass.; F. W. Bradley, President of the Bunker Hill and Sullivan Mining Co.; and Charles Butters. One of the features will be moving pictures illustrating Canadian Mining operations. Gold mining in Ontario, the asbestos industry of Quebec and the Trail Smelter and its allied industries will be portrayed.

Activity in Rossland Mooted—W. K. Esling, M. L. A., who is in Victoria from his constituency, Rossland, to attend the annual session of the Provincial Legislature, states that there is every assurance that, when the new concentrator being constructed at Kimberley by the Consolidated Mining & Smelting Company of Canada is completed, there will be a revival of mining in and about Rossland. The plant at Trail then, he says, will be used for the treatment of Rossland ores. The company's buildings and plant at the latter centre are being repaired and much development of the mines has taken place during the past four years.

Negotiations have been entered into by United States financiers, who were interested in the camp in its early history, for the purchase of Le Roi No. 2, the Josie No. 1 and minor fractional claims, and there is every prospect that the deal will be completed.

Proposed Ore-testing Plant—The suggestion that the proposed ore-testing plant, for which $100,000 is expected to be provided by the Dominion Government, shall be established at Vancouver, in connection with the University of British Columbia, is resented in Nelson. Fred A. Starkey, chairman of the Natural Resources Committee of the Nelson Board of Trade, asserts that it is incredible that Mackenzie King, Premier, has promised that the plant will be placed on the Coast. "The interior", he says, "is the only logical place for such an ore-testing plant;—here, right on the spot where the complex ores exist, not at the coast to be a toy adjunct to the British Columbia university—which is the Vancouver idea." He points to the 350,000 tons of ore treated thus far this year at the Trail smelter as an illustration of the need of the contemplated installation being placed in the Kootenays, as "practically all this is complex ore." True, the north may produce large tonnages, but that is in the future; the interior is the pioneer in mining and has been agitating for the plant for years. These and other arguments are advanced by Mr. Starkey in support of his position.

Rossland Properties Optioned—A report has been received from Rossland confirming the statement of W. K. Esling, M. L. A., regarding Le Roi No. 2 and the Cliff Group of Claims. Douglas Lay, manager of the company operating the "Josie", admits that an option has been granted to a syndicate of Spokane and New York business men. The Cliff Group is situated close to the "Josie" and it is stated that a tunnel will be driven to connect the properties. In the event of the deal being closed the "Josie" would be re-opened immediately and operated on a large scale.

Perry Creek—The Wild Horse Creek Placer Gold Mining Company has closed down work on Perry Creek. Mr. Palmquist, the manager, will leave shortly for Chicago. There has been much testing of gravel, as well as general development, during the summer and the Company is said to be looking forward with confidence to the results of next year's operations.

New Coal Mine in the Nicola Valley Field—What promises to be a coal mine of some importance is one being developed by Joseph Walters, ex M. P. P. for Yale District, a few miles distant from the town of Merritt.

The openings at the present time consist of a tunnel driven for approximately 200 feet. A splendid seam of coal is shown in this about 12 feet thick. A raise has been put up to the surface from this tunnel for ventilation purposes. At the point where the seam is penetrated by the tunnel, it is shown rising rapidly to the surface, and also dipping from the tunnel in the opposite direction, and from present indications, an extensive field should be developed.

The new mine is known as the Normandale. Mr Walters is to be congratulated on the splendid showing he has made.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertiserswill be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eigthpage, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale,Que., who can in all probability, refer them to proper sources.

EDITORIAL

These [engineers] are the men who, forming the advance guard of civilization, have conquered the wilds for humanity,...and who within the British sphere have developed new colonies, almost continents, to enrich and strengthen our world wide Empire.—R. G. Leckie 1897.

FORWARD, QUEBEC!

A few weeks ago we expressed the wonder, in these columns, that the autumn "rush" was not yet in evidence. At that time it had just begun, though the outside world had learned nothing of it. It has now reached the usual dimensions, in spite of its being centred in a region comparatively difficult of access. Contrary to the generality of rushes, it gives promise of resulting in the establishment of a gold-mining camp of first rate importance.

For years it has been known in a general way that the rock formations in northwestern Quebec adjacent to the known gold bearing rocks of Ontario are favourable to the occurrence of gold deposits of workable size and richness. In fact so many deposits of promise had already been located by the few pioneers that had worked in this area that certain of our geologists had committed themselves without reserve in commending it to prospectors. The Director of the Geological Survey at Ottawa, in particular, was so thoroughly convinced of the districts' promise that he sent Dr. H. C. Cooke's geological party into it last spring with specific instructions to do that detailed mapping of localities having the right association of rocks which is such a tremendous aid to the prospector. It would seem that Dr. Collins' faith both in the district and in this method of aiding the prospector is about to be fully justified. If the discoveries in Rouyn township and thereabout fulfil even a part of their present promise, the country will be repaid a thousand fold for the investment of public funds.

In his description today of the new gold area and the events that have led up to its discovery, Mr. Alexander Gray points out that, if there should result a gold field of sufficient importance, the extension northward of the Canadian Pacific Railway branch line from the foot of Lake Temiskaming to the Transcontinental Railway, often mooted but never as yet justified, would then be in order. The resources in agricultural land, timber and pulpwood that would be opened up by this 150 miles of railway do not warrant the investment. The added inducement of railway traffic created directly by a productive gold camp and indirectly by the contiguous settlement it automatically promotes would probably provide the stimulus to investment that is now lacking.

If Quebec is to have now, at last, its first substantial gold camp, mining in general throughout the province will be stimulated as never before. The history of mining shows that there is nothing so potent as a successful gold development in aiding the development of the other minerals. Quebec, with easy access to sea borne traffic on the St. Lawrence, is in a favoured position for overseas trade. We may logically look to Quebec as an important factor in Canada's overseas mineral trade in the future, and indeed in the near future.

THE TRUTH, THE WHOLE TRUTH, AND NOTHING BUT THE TRUTH

In commenting recently upon the various degrees of honesty and dishonesty displayed by the numberless stock flotations made lately on the basis of gold deposits, real or fancied, in northern Ontario and Quebec, we noted the fact that a number of promising properties had been handled, in some cases without intent, in such a way as to prejudice their chances of success. We referred specifically to injudicious expenditure of the money got by the public sale of stock as an easily avoidable waste. We wish to point out now a certain indiscretion that is rife in the raising of money, and affects even some of those that wish to be completely scrupulous in their dealings with the public.

Many people affirm their conviction that in order to convince the average man of the truth, one must resort to exaggeration. We do not believe that this is true, even in mine promotion literature. We are convinced, as is the larger fraction of our educated population, that exact statement, without exaggeration or misrepresentation of any sort, is by far the most convincing method. This method of informing clients and approaching prospective clients has been adopted universally by our substantial financial houses and agencies, and the growth, both in numbers and importance, of these concerns is a testimony to the efficiency of their method.

It is an ill founded tradition among mining promoters in general that over statement is necessary to a

mining prospectus or advertisement in order to convey the truth. In other lines of finance these exaggerated claims immediately brand the promotion as unsound, and the promoters as members of the catch-penny brotherhood. Mining promotion evidently has not yet advanced to this stage of clear demarcation between the true and the false.

There have lately been a number of instances illustrating this point, and, as it is a pity that through injudicious advertising and ill-conceived argument legitimate development and mining operations should be classed with the fakes and frauds that no genuine mining man can countenance, we shall name two of these.

The North American Gold Corporation lately took over the Ankerite property in the Porcupine district. The Ankerite has had a varied career; but we can state, with knowledge of the facts, that it is as near to being a mine, workable on a fairly large scale and at a reasonable rate of profit, as any property in the Porcupine district that has not yet proved itself by actual bullion production. The facts are clear enough, and are completely convincing. Yet the North American Gold Corporation, in its public announcements, makes ridiculous claims that purport to be based upon engineers' reports, but are actually gross distortions of the actual statements made. The property is of unusual promise. Such lying statements only decrease its chances of success. Fortunately this injudicious advertising matter has now been withdrawn from further circulation, and we can now look forward to a happy ending to the mining operations that are now to be resumed.

Abitibi Mines, Limited, own the Seagers claim in the Lightning River area, south of Lake Abitibi. In September last Mr. Cyril W. Knight, of the Ontario Department of Mines, examined the area, and reported that the vein on this claim and its geological occurrence were of great promise and worth thorough exploration. This from a conservative and cautious geologist known throughout the length and breadth of Ontario, is sufficient recommendation for any investor. Yet the prospectus of Abitibi Mines states that their nine claims "are now in an advanced stage of development," containing in one place "a body of exceedingly rich ore, assaying several thousands of dollars per ton," that "transportation facilities are excellent," and that there are "extensive ore bodies exposed." These are palpable half-truths that are not creditable to the men concerned in developing this property—men whose honest intention is undoubted and whose honest performance is beyond question. It were better to have let the plain, unvarnished truth speak for itself — it is much more convincing.

We hope that within the near future it will become the invariable habit of honest mining promoters to present their facts and deductions to the public in plain words, without exaggeration. It will pay.

A NEW PROCESS

Announcement is made in this issue of the "Canadian Mining Journal" of a new process for the utilization of feldspar.

Few problems have commanded so much attention as has that of devising some means of extracting from feldspar, of which rock there are literally inexhaustible deposits in this country, the potash that it contains. It has seemed that the question has always been aproached from the wrong side. Good potash feldspar will average from ten to twelve per cent in potash content. There are scores of methods of extracting the potash; but, when extracted, it does not yield enough to pay for the process. This, briefly, is the history of the great majority of processes heretofore patented.

The Brown process, however, is based upon the recovery of both the potash and the alumina contained in the feldspar. In other words, instead of utilizing only ten or twelve per cent of the rock, from twenty-seven to thirty per cent is converted into materials for which there is a demand commensurate with the growth of modern industry. We are informed, also, that the residue, which is silica, is marketable.

There is little need to impress upon our readers the tremendous national significance of a process of this kind. As operations have already been conducted on a semi-commercial scale, over a long period, there is reason to believe that the Brown process can be translated into actual manufacturing.

The first large-scale plant is to be erected in the near future. The "Canadian Mining Journal" extends its congratulations and best wishes to Mr. Brown and wishes to express the hope that his courage, perseverance, and unremitting toil will have the reward they deserve.

THE PROSPECTS FOR A ZINC INDUSTRY IN QUEBEC

On another page there appears a short resumé of the present zinc market of the United States and a forecast of conditions for the ensuing years. Mr. Kirby Thomas, among numerous other students of the case who have published their conclusions, looks for a steady demand for zinc and comparatively high prices. This conclusion has a direct bearing on zinc mining in Canada, and particularly in eastern Canada.

With ore that is phenomenal in its quantity and highly satisfactory in its combined metal content, and with a process now available for separating these metals, the production of unusually cheap electrolytic zinc from Sullivan ore at Trail now seems assured. Whether this metal can ever stand the expense of shipment to eastern Canada is doubtful. Meantime a profitable market in the Orient is assured.

Eastern Canada must produce its own zinc, if it is to have Canadian-made metal. Already there are a number of comparatively small zinc deposits located and partly developed, close to existing lines of railway. The commercial use of these deposits has been delayed, largely on account of the lack of a zinc smelter in eastern Canada, the comparatively limited market for the output of such a smelter and the uncertainty of a stable price for the metal. It may well be that the time is now ripe for the establishing of a self-contained zinc industry in the province of Quebec.

There is now a potential factor in an indigenous zinc industry that was lacking when its founding was first considered, and considered unfavourably. The zinc-lead deposits of Gaspé are now proved to be of unusually large extent, and give promise of being of the first magnitude and thus capable of being the sole support of a local zinc industry. To make the ore available, there is required a road from the railway on the sea coast at Cascapedia or Baie des Chaleurs to the heart of the peninsula, a distance of forty miles. As the provincial government of Quebec has refused aid in building this road except on terms that would prejudice the financial success of their venture, the owners of the deposits have undertaken the construction of the road themselves. It is a pity that money that would otherwise be available for mining development should be diverted to the construction of a public work — for this road will be of general benefit to that part of Gaspesia and is the pre-requisite to its development in all ways.

All things considered, we can look forward confidently to the establishment in Quebec in the near future of a zinc industry that will go far towards making us independent in our supply of this important metal.

EDITORIAL NOTES

It is reported that an organized meeting of feldspar producers and consumers has been arranged at a preliminary conference, this meeting to be held, probably in Washington, in December. The object of the meeting is to form an Association, whose principal concern it will be to formulate a set of standards, acceptable both to producers and consumers of feldspar, to regulate the various grades. Such a standardization of feldspar is entirely feasible and indeed is long overdue. The Canadian feldspar industry will benefit materially from the adoption of these standards.

We wish to draw attention to the letter on another page from Mr. H. Foster Bain, director of the Bureau of Mines, Washington. Dr. Bain wishes it to be known that the report, circulated in this journal as elsewhere, that the coal-cutting machines in use in Cumberland Colliery at the time of the recent mine explosion were of a type approved by the United States Bureau of Mines is untrue. We are pleased to publish this statement of the facts of the case.

It is highly satisfactory to note that the consistent and continuous efforts of Mr. Theo. C. Denis, Superintendent of Mines for Quebec, on behalf of the mineral industry of his province are bearing fruit under the present political administration. The provincial mining law adopted in 1909 was well conceived, but contained grave defects. One by one these defects have been remedied and the latest amendment, to be promulgated shortly, will give to the prospector, his financial backer and the Crown the best possible chance of profit by legitimate means and its fair division, while it discourages untoward practices such have retarded the growth of the industry in the past.

It is reported by the Chamber of Commerce of the United States that about $70,000,000 annually is being spent by manufacturers and others on scientific research. The computed return on this investment is $500,000,000 annually, saved as a result of this research work. Trade Associations, which are increasing rapidly in number throughout the United States, are entrusted with the direction of a large and growing part of this expenditure. The Chamber of Commerce lays especial emphasis upon the economy and efficiency with which it is possible for these Associations to conduct research. Canadians, wake up!

APPLIED GEOLOGY

Once had I quite a decent segregation
Of current coin for pleasant contemplation,
It was a source of honest joy for me,
A very enviable toy for me,
In time reactions slow, but also certain,
(As sure as moths performing in a curtain)
Set in. To my unbounded perturbation
I saw the cause — it was dissemination!
Enrichment (secondary) was my need,
My need enhanced by normal human greed.
So I forswore the complex fundamental,
And turned to oil promotions transcendental.
I learned petroleum patter — on my soul —
Until I sounded like a fumarole.
I prospered for a little while until
There came intrusion — call it what you will —
And contact metamorphic with the law,
Which superposed upon my fault its paw.
The treatment meted me was sure Satanic,
Plutonic I should call it, or vulcanic.
It left me highly altered, changed, and weathered.
Where I was "float," I'm now "in situ", tethered

J. C. M.

Letters From Porcupine--II

"INSIDE STUFF"

Little argument is needed to convince the most sceptical that intensive prospecting, that is, diamond drilling and exploratory shaft sinking, is badly needed within short distances, very short distances, of the town of Timmins. I believe that there would be something approaching an old-fashioned boom if closely held official information concerning unworked claims that border on the most important properties were divulged. As this is a highly improbable contingency, the accuracy of my belief is not likely to be tested. However that may be, there can be no question that much "inside" territory is favourable territory, and that it should have attention. I am disposed to agree with the Englishman quoted in my former letter to the effect that similar ground in South Africa or Australia would have been opened up long ago.

In this respect Porcupine is an ideal locality for operators who have had some experience in other camps. Diamond drilling can be carried on cheaply and expeditiously. It can be made determinative now more rapidly than it could have been two or three years ago. The commitment in drilling is relatively small compared to the possible and probable prize.

For "inside" exploration, then, diamond drilling seems to me the "better 'ole". It is a much saner way of applying money than is the usual purchase of share control in organizations that already have a load of over-capitalization to carry.

* * *

It is noteworthy that the total mining, milling, and administration costs chargeable against each ton of ore handled in the three large producing plants of Porcupine are considerably lower than the objective set by Transvaal operators in their present struggle to reduce costs. On the Rand costs ranging between $6 and $7.50 per ton are not so usual as are even higher figures. Judging from the histories of both regions, it seems safe to assume that mining and milling costs will remain lower in Northern Ontario than on the Rand.

This is due, in part at least, to the brilliant—and little advertized—achievements of two men whose work has made milling history in Porcupine and, indeed, has given some permanent additions to the science of ore treatment. To mention names would be unfair. To a certain lesser extent other men share the credit of bringing milling practice in Porcupine to its present condition. It is not, however, the fact that costs are low and extraction high that is the most significant feature; it is, rather, the equally patent fact that constant improvements are being made. The spirit of the camp is right.

* * *

The path of the independent assayer in Porcupine is a thorny one. He must compete directly with the Government establishments. Much work that should be his is done in mine assay offices. In fact he not only gets no protection at all, but there seems to be a conspiracy to put him out of business. Whatever the merits of the case, the independent assayer assuredly gets a raw deal, a deal that has been raw so long that decay has set in. He asks for bread—and he doesn't get even the stone substitute. In all fairness the mining fraternity should do something to rectify this inequity.

The mining companies that own widely distributed undeveloped properties in the central townships have their chances of success greatly augmented by work that is going on now. This statement applies particularly to the townships of Tisdale, Deloro, and Ogden. From what I have seen during numerous inspections of properties in the latter two townships, I should venture a mild wager that developments in the next six months will greatly improve the status of both. There will then, I hope, be no longer any imaginary need of trading on the glories of the long-suffering Hollinger, Dome, and McIntyre to bolster up a flabby prospectus.

Most encouraging results are being reported from at least two localities to the north-east, outside the unofficial boundaries of Porcupine proper. These are what the oil driller would call "wild cats", by no means a derogatory term. They are legitimate ventures in unproven but exceedingly promising ground. More power to them! May no croakers be permitted to discourage them!

* * *

Within limits "high grading" is considered a venial sin. It is winked at by the "high gradee". As witness the following: While examining a lot of rich specimen ore displayed on the dump of a Porcupine mine, a super-ethical Canadian professor was observed surreptitiously jamming a few of the choicest pieces into his side pocket. Technically that professor is quite as liable to arrest as were recently extradited children of sunny Italy. However, the prick of conscience that he will suffer when he reads this will be his only punishment.

J. C. MURRAY

CONTRACTOR AND COMPANY FINED

On information laid by Mine Inspector James Bartlett following his investigation of the recent fatal accident in the shaft of the Herrick Mine, West Shining Tree, Ontario, those responsible under the Mining Act of Ontario have been prosecuted and fined.

Felix D. Henderson, contractor in charge of the shaft sinking for the Tonopah Mining Company of Nevada, was fined $500 and costs by Police Magistrate D. M. Brodie, of Sudbury, on November 2nd, 1922. The charge was that a cross head not equipped with a safety device was in use in the shaft. The Tonopah Mining Company also were fined $500 and costs on November 3rd., by the same magistrate, on being found guilty on the same charge.

Thus is the law upheld in our land, at the price of ceaseless vigilance on the part of our corps of mine inspectors. Seldom do the public hear of the activities of the guardians of the law, whose principal concern is the safety of life and limb in the mines. Yet the mining acts of the various provinces are among the best administered of all the laws of our country.

Quebec Gold Area Being Established

THEIR EXTENT, MINERALIZATION AND RECOGNITION BY KNOWING INVESTORS ARE MAKING THAT PROVINCE THE MECCA OF THE MOMENT

By ALEXANDER GRAY

Prospectors, those pathfinders of the solitudes who wrest wealth from the wilderness, have been busy for two years in Northwestern Quebec. The result is the preliminary demonstration of a gold field or fields of major importance. That is why Quebec has changed its Mining Act so that "blanket" locations cannot be made except by license and actual staking. This change has not been officially promulgated, but will be in a few days. Work and pay will be pre-requisites to patenting.

Following the sign-posts of Miller, who quietly foretold that the pre-Cambrian shield sheltered Quebec's share of the precious mineral wealth for which Porcupine is now noted, "although the geological features may not be of the same age," accepting the judgments of Scientists such as the Wilsons, Tanton, Barlow, Burwash, Parke, Bancroft, Knight, Burrows, Bell, Dresser, the youthful Hopkins, Mailhiot and latterly of Cooke, the "sourdough" fraternity has effected another peaceful revolution by making the waste places of Gaspe and of Pontiac County of Quebec, arenas for more of those Great Adventures that romantically adorn the pages of history.

Beginning at the interprovincial boundary, extending east toward the Harricanaw River and south from the Height of Land, near what is known as the Opasatica section; revolving round Rouyn, Boischatel and adjoining Townships, and based upon the Rainboth-Blouin line, in the midst of a territory heretofore written off by almost all others than the lumberman, trader and trapper,—enough favorable geology and gold have been found to form the nucleus of a "boom."

Country Being Rapidly Acquired

Thousands of acres have been staked and are to be surveyed. The rocks are right and the fracturing favorable. Out-cropping ore bodies have induced representative mining engineers and well informed, alert prospectors to locate areas and take title to blocks of ground. Perhaps it is a trifle early to indulge in prophecies as to the extent of the gold fields and consistency of the values. Temporary suspension of these and admitted inaccessibility, may not preclude snowshoe staking, and will not deter the more enthusiastic from sharing the ardent view of the Goudreau prospector who declared: "Why, there's so much gold, the feathers of the fowl are covered with it!"

Flights of fancy, when seasoned with fact, are permissible in the circumstances; but they do not make a gold field. It is more to the purpose to have it authoritatively known that Quebec has joined in that development which has made Ontario the most attractive play-ground for speculative capital. The Scientist said Quebec would be reached by evolutionary stages, if not by aggressive exploitation. It has been. One section sampled along about a thousand feet is alleged to have given various results of $15 to $25 across 8 ft. That will suffice, when more convincing evidence is forthcoming. As a prospectus it has more substance than a lot of what is appearing in the public prints, representing a surface showing as "another Hollinger," a mere handful as "the greatest ever." It is more to the point and satisfactory to have it that Quebec's gold country is undergoing preliminary "enquete". It will take next summer to complete the testimony. Meanwhile eminent authorities are impressed. Scientific judgment is being justified. Current events sustain these forecasts.

Quebec Superintendent of Mines Denis in 1910

"Of the resources which were practically dormant for a long time, Gold requires a special mention. The Province of Quebec comprises an area of about 375,000 square miles, of which the southern belt alone is comparatively well known as regards its mineral resources. There remain over 300,000 square miles which are practically unexplored, and which offer to the prospector a field fraught with possibilities. There are at present two regions which are attracting special attention, viz: the region between Lake Abitibi and the Ottawa river, immediately to the east and northeast of Lake Temiskaming, and the Chibougamau Lake region, 175 miles west of Lake St. John. In both of these regions, as well as in the territory between them, there are large areas of Huronian and Keewatin rocks and it is in the rocks of those formations that occur the silver deposits of Cobalt, the gold deposits of Porcupine, of Larder Lake, the Nickel deposits of Sudbury, the copper deposits of Bruce Mines. There is little doubt that the 'hinterland' of Northern Quebec contains immense mineral wealth awaiting the hardy prospector."

Professor J. Austin Bancroft in 1912

"Considering the discoveries of gold which have been made in the vicinity of Kienawisik Lake, diligent prospectors should carefully examine every acre in this vicinity with the well-founded expectation that much better discoveries may be made. During the past summer (1912), numerous prospectors were in the district, but by far the majority of them restricted their endeavors to the rock exposures on the rivers and lakes, soon becoming discouraged by those difficulties with which they were called upon to contend. Until no stone has been left unturned, this area offers more reasonable hopes of reward than those vast expanses of country within which discoveries have been made. Prospecting should not be concentrated only in the vicinity of Kienawisik and Blouin Lakes, but should be extended to adjacent areas, especially to the eastward and westward of Kienawiski and Blouin Lake and the narrows extending to Lemoine Lake. At the time of our examination of the area, these discoveries of gold that had been made pertained to veins of narrow width and of such character that further expenditure of money was wisely being devoted to a search for veins of greater promise. It is to be expected that thorough prospecting will be attended by such desirable discoveries."

The First Move

Four years prior to the organization of the geological field parties of which Dr Bancroft was one of the chiefs, the writer, at a privileged session in the Government Offices, at Montreal, persistently urged the unwisdom of Quebec indifference to mineral developments immediately west of the interprovincial boundary. Minister Devlin was courteous and earnest. He acknowledged the urgency of having a provincial laboratory, and assented to the idea of mapping what was

somewhat unsurveyed territory, if not the province as a whole. A month or two later, however, a curt note was received by the petitioner to the effect that if my idea was to interest the province more largely in mining affairs, it could not be entertained.

That was in 1908.

Now there is a Mines Department presided over by a more responsive, capable Scientist, who in 1910 thought the "hinterland" of Northern Quebec had rewards "awaiting the hardy prospector". Mr. Denis wrote a pamphlet for the National Exhibition at Toronto in 1910, from which I quote an excerpt. Meanwhile the "hardy prospector" had left his imprint upon the pages of Ontario's mining history; so, in 1921, Mr. Denis returned to the issue and incorporated this in his report.

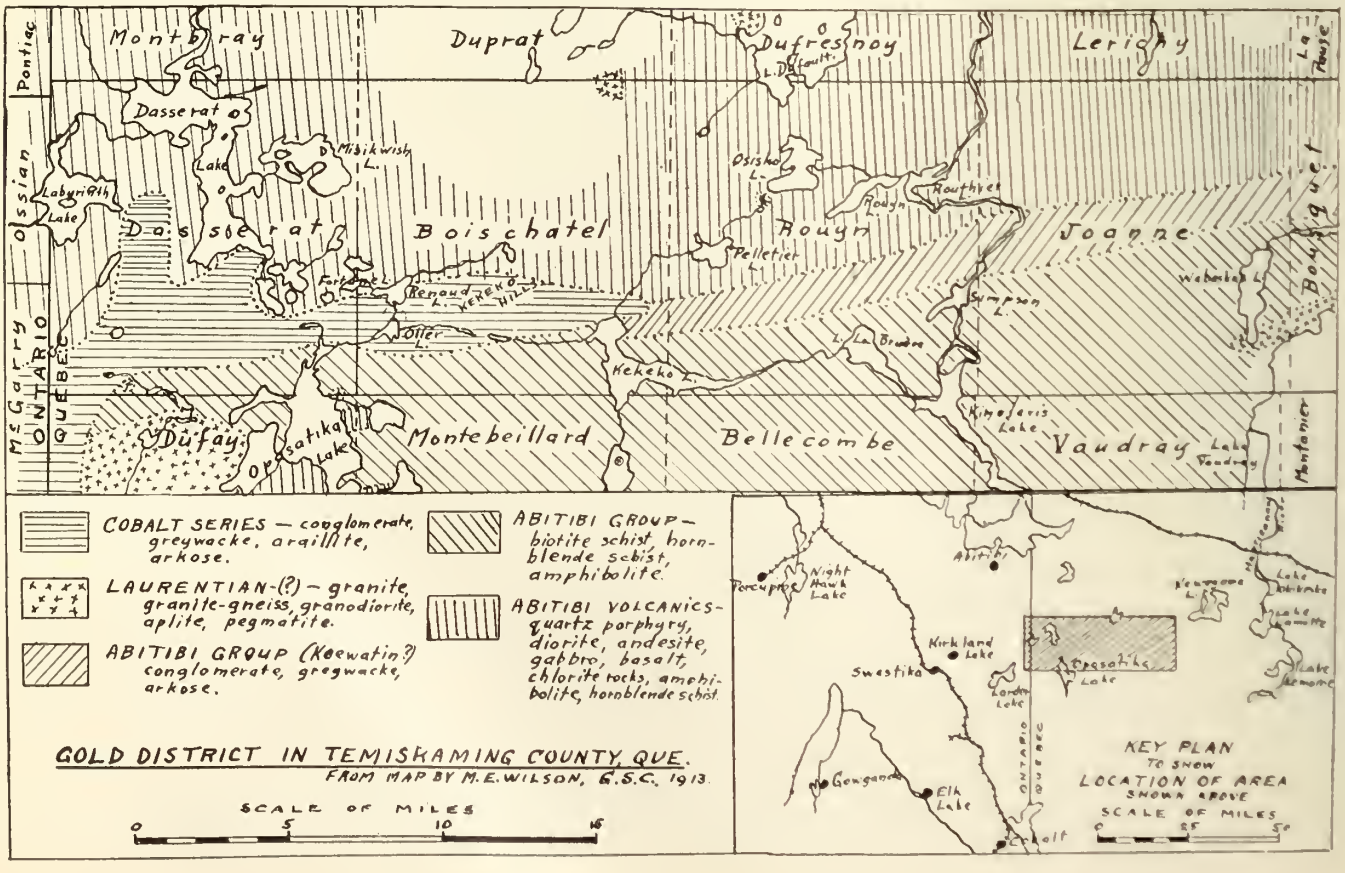
> "There is at present no gold industry properly speaking, in the Province of Quebec, that is production of gold from quartz veins or from Placer deposits, although the province possesses both kinds of deposits. Very promising areas containing gold-bearing veins are known to exist in Northwestern Quebec, in the region of the Transcontinental railway, east of the interprovincial boundary between Ontario and Quebec. The geological conditions in this region are very similar to those prevailing in the mining regions of Ontario, such as Porcupine, Kirkland Lake, Larder Lake, and a gold mining industry will certainly develop in time. While these two areas are the most prominent of the Quebec gold districts, the presence of gold quartz and of gold-bearing sands has been observed in numerous other places in the Province."

"Crooked is The Path"

By the tortuous route Quebec eventually is achieving what the Scientists foresaw. It has not been a royal road to the disclosure of wealth. For almost twenty years Ontario has been upon the tidal wave of mining prosperity, occasional spills being only temporarily disconcerting. Most of that time Renaud has hibernated around Lake Fortune. Olier joined him and had a lake named after him. They found gold at Opasatica. More gold was reported further east at Chibaugamau. Preferences fluctuated between the Abitibi-Opasatica and Chibaugamau sections, so-called. Expert testimony by Miller, Brock, the Wilsons, Bancroft, Tanton, Barlow, Denis, Miller, Knight, Burrows, Bell, Dresser — a goodly array — bearing upon the geology of Northeastern Ontario and Northwestern Quebec, did not disturb the pastoral serenities of Quebec, which was advised by the late Mr. Obalski that the gold discoveries of Olier and Renaud were unimpressive. It almost seemed as though there was constitutional objection to mining developments in the largely uncharted province, with its undoubted possibilities as disclosed correlatively in Ontario. Singularly, though when Cobalt was in its prime, the reasonable inference was that the Quebec area east of Lake Temiskaming might reveal silver. The follow-up fell short.

A Road And Railway Ready

Consequently, and rather casually, Fabre and adjacent townships were given the "once-over". A few showings were noted, and official cognizance given them, but precedence went to "the diabase" and "bloom" of the Montreal River country. Really, the thought of gold was not seriously entertained, after misadventures in Western Ontario, and the ferruginous dolomites of Eastern Ontario and adjoining Quebec territory were considered unpropitious. In 1906 Mr. Obalski, on behalf of the Quebec Government, had commented rather equivocally upon what Olier and Renaud found near the height of land in Quebec, where Revillon Brothers, anticipating an influx of prospec-



tors, established a store at the head of Lake Opasatica. The original "hardy" prospectors were years ahead of the good wagon road now approaching completion from North Temiskaming to Opasatica and the enterprise of the Canadian Pacific that is feeling for the opportunities in that vicinity, intending, if the situation warrants it, to extend a line north to the Transcontinental. Recently the Dominion Government sent Dr. Cooke, who looked into the settlement and mineral possibilities of the section. The Canadian Pacific seeks tonnage. The "hardy prospector" remained in suspense for almost two decades, notwithstanding the trained scientific observer made it of record that nothing should be left undone to locate what Ontario was presenting in the way of economic minerals. For the policy of procrastination the Quebec Department of Mines was not at fault. Mr. Denis not only has been alert; he has been progressive and made his official documents a standard of excellence in contents and letter-press. Somehow and simply, Quebec was given the go-by during the probationary years since Porcupine was found.

Scientists Supplied the Lines

It is customary to have that matter-of-fact Scientist, the Geologist, ironically described as someone who "never made a mine". Glamour goes to the "sourdough" fraternity. What Ontario and Quebec (all other mineralized areas for that matter) owe to "Bergassessors" (the "Rock-knockers") never has been written into poesy by even the immortal "Anon." Politicians will have it that the "rock-hound" is an excrescence. However the "clay belt" is an Eldorado, and, instead of pelts, Quebec presently is going to talk in the language of Boisehatel, Rouyn, Dubuisson, Pelletier, Routhier, Osisko, Okikeska, Askikwa, Kienawiski and Lemoine—not overlooking Opasatica.

There is another map in the making. Deeper respect may be engendered for the Quebec section of the Transcontinental Railway and its tributary areas, while the Canadian Pacific is "spying out the land" and thinking of driving more stakes. What is going on in all probability could not have been accomplished ten and fifteen years back, for now there are accessory transportation facilities. Even now much of the Quebec mineral-bearing section between the Harricanaw and the western border, is no place for the faint hearted and weakling. To be sure, Quebec, until Mr. Denis convinced his chiefs that the rainbow did not stop at the Ontario border, was rather unconcerned. A monument may yet mark the location where Olier and Renaud fruitlessly toiled on the fringe of formations in and next door to auriferous areas comparable with those of great portions of Ontario. The prospectus of the Pontiac and Abitibi Company published in 1908, reciting how much profit was about to be obtained per annum ($3,000,000) was pleasant somnambulism—not a "beauty sleep."

How The Pendulum Swung

Opasatica was tested before Porcupine. Lake Ollier and Lake Fortune were the scenes of excitement, and subsequent derision, when the late Mr. Obalski was dissatisfied with his sampling results. The Pontiac and Abitibi and Union Companies left their mark—with a cross. Simultaneously Larder Lake was painted "couleur de rose" and capitalized accordingly. Chibaugaman, too, went rocketting—with the usual result of pyrotechnics. However, those episodes did not differ in detail from the Ontario mishaps that left the people of the province with debts and doubts. Rainy River and Lake of the Woods tallied with the prematurities of Rossland and environs. Following so closely upon the high pressure days of Cobalt, zest was given to snow-shoe stakings at Larder Lake in the first decade of the century by the glowing accounts of the values and widths. It was an entrancing moment when the human calliope gravely informed me in the lobby of the Prospect Hotel at Cobalt that "the only way to deal with the Harris-Maxwell is to put the whole thing through." And as for the Reddick—put the wealth of the Indes, the lucre of the Incas and the output of the Land of Ophir into the muffle, and the bead would be infinitesimal alongside of what the Reddick would contribute.

Then Nighthawk, in 1907, displayed its charms, to be laid away for another thirteen or fourteen years, suitors being scarce. Painkiller in 1908 did not have a soothing effect. Munro was a shooting star, in 1909. Porcupine contemporaneously became fixed in its orbit, and no telescope is needed to locate it. This is not true of Swastika (nativity, 1910) christened and interred in infancy, despite keen competition in propitiating the emblem of Good Luck.

In rapid sequence so many "discoveries" were reported, and so much was staked in the pre- and post-Porcupine period, that the Maple Leaf seemed to be supplanted by the Gold Leaf in Ontario. If the find was not "another Hollinger" it was "another Dome". When the supply ran short, "Reserves" and "Extensions" were requisitioned, unmindful of the fact that "another Kerr Lake in the diabase" has yet to be found.

Where Quebec Was First Jolted

Perhaps the most joyous days are those when blazes and beams predominate. This is written without attempt to disparage "bootlegging" incidents and illicitly-obtained moose-meat. There was massed wealth when Latchford was the seat of Government, or Elk City. The air was filled with cadences when Jondoin joints and Crawford's and Hill's were the abode of embryo millionaires. Olier and Renaud sought the by-paths at Opasatica. Mosher and his mates took pot-luck at Abitibi. The former duo had sufficient to induce them to purchase two blocks of land from the Quebec Government, Mr. Obalski reporting that "fine samples of quartz, showing gold, were produced with the applications." Part of that ground was transferred to the Pontiac and Abitibi, and some of it to the King of the North Mines. Corporate existence, though, was jazzed by the visit of Mr. Obalski in 1907, and this comment:

> "I visited this property again and found that very good progress had been made during the year, consisting of the discovery of numerous veins of quartz from a few inches to several feet in width, on which shafts 15 to 20 feet had been sunk. I was shown pieces of quartz containing gold, taken from those veins and, as stated last year, by washing the earth and debris around several of those veins, I found fine colors of gold, especially at the shaft where the discovery was made near Lake Fortune, the rock there having a certain analogy to Larder Lake. The general formation of this region is greenish diorite [illegible] fairly compact and quartzose traversed by veinlets and veins of quartz which do not seem to have

any special direction. South of Lake Olier is a considerable development of very hard, reddish porphyritic rock. These same eruptive rocks are also met with after crossing the height of land, on the eastern shore of Lac des Isles. I took several samples of quartz which I had assayed and which yielded no gold."

Otherwise put: The stockwork did not make the grade. Cooke and Hopkins supplementing what Bruce wrote, held that ferruginous dolomite without requisite mineralization and intrusive auxiliary factors, was lacking. Singularly enough, Olier and Renaud hibernated near where there existed the wealth Dr. Bancroft foretold. The Great Northern Gold Fields Company was pretentious in name only. Silicified dolomite, mixed with schistose serpentine, was too serpentinous. Of the eruptive masses noted by Mr. Obalski, who assumed they contained "elements of granite", it is not importable that if he had gone into the field prepared for further explorations, he would have found corroborate evidence of the potentialities of the district—those beneficial intrusions of porphyritic masses, the syenite porphyry and the faultings that have resulted in "desirable discoveries", as Dr. Bancroft expressed it.

The Montreal River Deflection

Had Mr. Obalski and others given the locality the requisite detailed investigation, the volcanic rocks more recently mapped would have conveyed their true significance and Quebec would all the sooner have joined the gold movement. Fifteen miles away was Larder Lake, now becoming opprobrious. Callinan and Mosher at Nighthawk and Abitibi Lakes, respectively in 1908 were "as one crying in the wilderness." The movement had been east and northeast prior to Porcupine. Larder Lake printing presses having broken down, the "die-hards" of Quebec clung to Chibaugamau while the "hardy prospector" would have it that every forty acres throughout the Montreal River country represented from one to five millions as a starter. Shooting the rapids or portageing round them were all in the day's work toward silver in car lots. The Gowganda trail became the Appian Way. Hyperbole was universal in describing the "bloom" and "native". The "Downey", "Otisse", "Moose Mountain", "England's Premier" hundreds of incorporations reflected that "incorrigible optimism" which is admirable if expensive. Strenuous capitalists contended for the "Mann-Ryan". The "Boyd-Gordon" was entrancing. "Reeve-Dobie" and more "Silver Sidewalks" than Drummond could poetically depict. And when the "Blackburn" became the "Millerette", and the O'Brien-Sifton coterie bought the Bonsall and other claims, there was nothing to it but silver by the square league and limited trains to the White Lights, by way of celebration.

Porcupine Sustained and Disapproved the Scientist

Meanwhile Quebec had no silver east of Lake Temiskaming. Montrealers kept faith in Lake Fortune, Chibaugamau was under the ban of "Missourians" who had not been "shown". Not until Porcupine geology, mineralization and the relationship of shearing and porphyry had been accurately delineated by Miller, Knight, Burrows and others, whose horoscopic estimate of the pre-Cambrian country has been the basis of much of the development, was the prospector recompensed—and more often disillusioned. One school of scientific thought pronounced Porcupine to have "bull" quartz; decidedly lenticular veins in schist, and never-never shear zones. There were incredulous Canadians who decried the structures and condemned the mineralization. Prospectors and more venturesome speculating capitalists absorbed areas from Nighhawk and Frederickhouse Lakes to the Mattagami River, and overran the Temagami Forest Reserve. "Quartz" was the slogan, regardless of precedent occurrences. Gold by the square mile was taken for granted. It became the vogue to have quartz and schist, instead of the diabase. "bloom," smaltite and native silver of the Montreal River era.

Prospectors and all concerned had to learn that mineral deposits make their own differentiations during periods of deposition. There will be more producing mines at Porcupine, but there are fewer of them now than there were at the outbreak of the War. Swastika and its townsites are so many blanks, so far as outputting goes. In 1911 Shining Tree and the "White Guide of the Temagami" were to the fore. Whiskey Lake was appropriately celebrated. For a while the gold development was rather intermittent, Kirkland Lake alone being accepted as assuredly supplementary to Porcupine. Kirkland Lake gave renewed impetus, and the wherefore of this is tersely stated by Dr. Goodchild, of London, who made an exhaustive study of that section in particular. He writes:

> "The whole of northern Canada in modern times has been covered by a thick mantle of moving ice. This ponderous cover of ice gradually scraped away the rock surfaces over which it slowly moved for ages, mechanically grooving out the least resistant portions of the land surface and leaving the harder and more resistant portions standing in the form of low rounded hills with intervening shallow valleys together with a multitude of lakes and swamps in the deeper hollows, the latter resulting from the subsequent passing of this period of intense glaciation.
>
> "Faults and shatter zones are obviously lines of weak mechanical resistance to such drastic erosive action. Hence the topography of the present dry land surface is an important aid to the interpretation of the structural geology. A cogent illustration of this is the Lake Shore Mine which is at the moment of writing the richest developed property on the Kirkland Lake Goldfields. The orebody is situated beneath the lake and this is no mere accidental circumstance, for a great part of the lake system of Canada and many of the more important rivers course on the banks of great faults and fracture zones that were originally grooved out by glacial erosion."

Gold-Seekers Begin To Look Eastward

So much for topographical features. More than one mine at Porcupine and Larder Lake has been a source of anxiety before structural features and the significance of faultings were elucidated. Beginning in Quebec, before Porcupine as a gold field was of record other than by what Burwash and Parks had foreshadowed, interest had alternated; but prospects fell short of requirements. The Pearl Lake and Dome sections proved to be more educational in value than in production, almost; for only from scientific prognosis and practical demonstration was it made conclusive that Northern Ontario was the most promising of the new gold countries. Going west from Porcupine as far as Shining Tree, the army of adventurers counter-

marched to Kirkland Lake, thence to Lightning River and the Harricanaw and finally to the Townships of Boischatel, Rouyn, Dubuisson and others, immediately west of the Harricanaw where Dr. Bancroft wrote that "systematic and intelligent prospecting of the areas of other rocks should be attended finally by the discovery of minerals of value; but, unfortunately, over by far the major portion of this region, efficient prospecting will always be a very arduous task. Owing to the heavy and almost universal overburden of stratified clays and sands, outcrops of rocks are very widely separated. Inland from the waterways, the country is covered by a blanket of moss, and rock exposures are confined chiefly to the very sparsely distributed low hills and ridges; but, frequently, in making traverses of the bush one will find outcrops of rocks when least expecting their presence."

Present Day View And Events

Cooke had it that, according to all accounts, the geology of the Porcupine district is essentially similar to that of Opasatica. Professor Mailhiot, reviewing the work of W. J. Wilson and M. E. Wilson, Bancroft and Tanton described the rocks of the Pontiac and Volcanic Abitibi Series. Unfortunately, three years ago Professor Mailhiot did not reach the scene of current activities, in generally referring to which the Honorable Minister of Colonization, Mines and Fisheries, of Quebec, J. T. Perrault, officially wrote last week:

> "On casting a glance over a map of Canada, one is at once struck with the tremendous area indicated as 'Province of Quebec'. With its 706,000 square miles, Quebec is the largest of the Canadian provinces. Of this expanse, 90 per cent. is practically unknown as to the mineral resources, but from geological data at hand, its potentialities are very great. The northern 500,000 square miles, enormous as it may sound, is at present difficult of access to the average person. But the balance, constituting the southern third of the province offers an ideal territory to the individual prospector, for the canoe routes are innumerable, and the railways bring all parts within reach. Colonization and mining, in new districts, work harmoniously as each helps the other. The mining camps constitute a natural market for all the produce of the settler, at prices higher than those obtaining in older settled parts, and the miner, however high the price he pays to the local farmer, gets the product cheaper and fresher than if he had to bring it in from distant parts."

Progress Evolutionary Rather than by "Leaps"

Minister Perrault need hardly have emphasized that Quebec progression has been slow but sure, steady rather than by "spectacular leaps and bounds." He expressed his conviction that the mining industry of the province is yet in its infancy, with the possibilities offered "second to none anywhere". It is obvious why Quebec has been on the deferred list. The Mines Department of the Province could not have accomplished more, with the facilities at hand. Because of the Eastern Ontario developments, the Quebec foundation is all the surer. Whether it be in the Lake Montigny, Lake Blouin, Lake Lemoine, Lake Piche area (known of for more than a decade) or between these and the Ontario border, evidence is accumulating that Quebec has more than "potentialities". Even though the demonstration of this has been slow, while previous discoveries and work have not attracted other than Canadian capital, the exploitation of the Martin ground, publicity given to the Siscoe and Sullivan (all in the Lake de Montigny area) certainly accelerated the pace. Perhaps Professor Mailhiot's epitome of the past will serve to show how pioneers have fared:

> "The first gold discoveries in the Lake De Montigny region date from 1911. On the 11th of July of that year, Messrs. J. J. Sullivan and Hertel Authier discovered gold on the east shore of Lake De Montigny in a quartz vein which has become (1919) No. 1 of the Sullivan property. The discovery become known only near the end of the fall of that year and a great many prospectors were attracted to that region. In the same year two gold-bearing veins were discovered on the property owned by the Martin Gold Mining Company, Limited, (now being developed by New York people). In the following year (1912) two other veins were discovered in the region. One, the Smith vein, at some distance south of Lake De Montigny, which was staked by different persons after its discovery and now belongs to Mr. George Neveu, is situated on lots 44 and 45, range VIII, Dubuisson township. The other, the Benard vein, now owned by Mr. Tancrede Marsil, is situated on lot 39, range I, Varsan township. In 1915, on Siscoe island, the largest in the lake, gold-bearing veins were also discovered on the claims now belonging to the British Minerals Corporation, Limited. Besides the work done on the island by the Siscoe Mining Syndicate and on the Martin property, where development has been done and a mill has been put up, very little prospecting was done during the War. Since the signing of the Armistice, a great many prospectors have gone to the region around Lake De Montigny and have made discoveries; among which the following may be mentioned: the Stabell, Legault, Parker, Clowse, Caron, St. Germain, Gale, Craft, Foisie-Kengow and some others."

Of the Siscoe, it has been reported that "the gold is found in veins and stringers of quartz in which there is a good deal of tourmaline, a little calcite and an abundance of iron pyrites." Dr. Bancroft, Professor Bell and John A. Dresser were of the opinion that the values obtained and nature of the occurrence were sufficient to "warrant undertaking further development work." Professor Mailhiot in reviewing the Martin property said there were "ten different veins, five of which were main veins and five were outcrops of lesser importance. The company had "a shaft 125 ft. deep, with cross cuts and drifts 100 feet long, in a vein of gold-bearing quartz, explored on the surface."

The Scene Shifted Nearer to Ontario

Leaving the original properties and what they may possess, in the Harricanaw country, where Lake Okikeska is now Lake La Motte, Lake Askikwaj is Lake Malarlic, Lake Kjenawisik is De Montigny—forgetting the height of land molybdenum of fifteen years ago—Mr. Obalski on his flying surveys of those years was keenly observant. About that time Quebec raised the price at which mineral lands could be purchased and limited the area obtainable by individual applicants. Near the Harricanaw tributaries Mr. Obalski saw diorites, porphyry and syenite, but differed from Mr. Brock in his definition of the silicified dolomites of the Larder Lake-Abitibi Lake sections.

No more than cursory reference can be made to the number of discoveries made at the Sullivan, Stabel, Martin, Neveu, Callinan and others. They have the same relationship to what is going on at this moment, as the Hunter find on the south shore of Porcupine Lake had before Wilson and Hollinger were heard of, and to that pit sunk on what became the Dixon (the Acme Area of Hollinger Consolidated) long before Pearl Lake was crossed on the ice by Noah Timmins and his newly-purchased horse and wagon.

Regarding this Stabell property, an effort is to be made to develop it under strong Montreal auspices. During the past week arrangements to this end were completed. The outcropping ore-body is in the basalt and is intersected by a syenite porphyry that cuts through it. Stripping has been done for several hundred feet and the values compare with the average of the Kirkland Lake field. It is proposed to drill this very promising vein, sink upon it and do considerable lateral work. For this the money is being provided; so the Stabell will have a chance it has been denied by reason of the exacting conditions of the owner. Undoubtedly the Stabell is a likely, substantial prospect, and is deserving of what the interested Montrealers propose to do.

Quebec was not ready for diversion. Porcupine brought down upon the head of the writer the maledictions of a very lovable impetuous scientist, when it was publicly recorded that the values in the Dome crosscut at the 45-ft. level averaged $12.42, and that Legget had given the Hollinger shallow workings and outcrops a general average of $37.50. Nighhawk was in the discard.

Governments, like capitalists, have to be convinced. Government Geologists are as prosaic as many of the minerals they are called on to deal with. Sixteen years elapsed until Minister Perrault could publicly proclaim that Quebec is another Land of Promise and prospective performance, even though its Northwestern section be difficult of access and only for strong combinations to explore. That being so now, all the more is due to the memory of Mr. Obalski, who made that exploratory trip in 1906 from Ville-Marie to the Baie des Quinze, thence to Lake Expanse, following the Ottawa to the Kinejeviz, up that and the Keegama, and on to the Harricanaw. Mr. Obalski had to stick to his canoe route (as the writer told the late Minister Devlin) and could not do more than that. He skirted the region on the east, missed the very thing he was seeking, notwithstanding he said he felt keenly the desire to duplicate "the important discoveries made at Cobalt" and assumed "the same Huronian formation existed in Quebec." Mr. Obalski, like Messrs. Mailhiot and Bancroft, had a defined area to pass on, although Mr. Obalski was free to go wherever he could with his limited party and equipment.

Within almost a township's length, where the Rainboth-Blouin base line was run, the rush is on, and the snows of winter, flies and mosquitoes of summer, muskegs and charred, fallen timbers, complicated by drift and moss, will not stop the staking. Much of this already is foredoomed to failure. As usual, there has been staking in and out of lakes, on superimposed Cobalt series rocks—anywhere and everywhere on the off-chance of favorable ground. Quebec Mining Laws are liberal, especially when applicants are responsible citizens. Holders of ground with something or nothing are elated at what they look for when the break-up comes next spring.

Where It Is

In the row of townships extending from the Ontario boundary—Dasserat, Boischatel, Rouyn and Joanne—based upon the Rainboth line of 1897 and the Blouin line of 1906, is where all this eager staking is going on. Therein is the Pontiac series of the Abitibi group. As already intimated, the Olier and Renaud claims (Pontias, Lake Fortune and King of the North Companies) were just to the west of the Kekeko hills, on the edge of the overlying Cobalt series. There is a stretch of this Cobalt series extending to Lake Kekeko. Immediately to the north are the biotite schist, hornblends schist and amphibolite. Immediately north and in contact with the Cobalt series is the expanse of Keewatin rocks,—the Abitibi volcanics, quartz porphyry, diorite, andesite, gabbro, basalt, chlorite rocks, etc., as defined by the Wilsons, Bancroft and Brock. Underlying this Cobalt series, seemingly, in the Townships of Dasserat and Boischatel, is a section of conglomerate, greywacke and arkose rocks, which traverse in a northeasterly direction the Townships of Rouyn, Joanne, Bousquet and Cadillac. The whole area is lake-strewn, matted and made difficult by fallen timber, many outcrops being chance discoveries.

Generally speaking it may be stated that the region was originally underlain by volcanic rocks of Keewatin age, mainly rhyolites and basalts. There are granitic intrusions succeeded by syenite porphyry, similar to that of Porcupine, Kirkland Lake, and to some extent of Larder Lake. The porphyry occurs in masses and as dykes connected with the masses. In places the schisted basalt is cut by quartz veins, and there are shear zones in relation to the porphyry which make those localities in particular objects of greater interest.

At the moment, the western end of Rouyn Township has been staked or acquired by agreement with the Quebec authorities. Everything around Pelletier Creek and Pelletier Lake, to Osisko Lake, is held. Horne started it a year ago, the Cockeram Brothers, Arthur and Robert, Marty Wright, Billings, Davies, Gamble, Charlie Richardson, Fred. Connell and Powell following, until there is no doubting the strength of the column. What Sam. C. Thomson and his associate, Mr. Chadbourne, have in their own right or by option, they have not divulged. Mr. Thomson is a mining engineer of international repute and conceded good judgment in new country.

Messrs. Thomson and Chadbourne have all or part of the Cockeram and Powell under agreement, and some of the Horne ground. Ottawa people are behind Robert Gamble. The breaks are said to run northwest-southeast.

Most of the areas are held in blocks of a thousand acres or two, so there is ample scope for those with the requisite capital. The breaks are pronounced. If one line of outcrop differs from Kirkland Lake in that the average values are alleged to be between $15 and $25, as sampled, there is a sound basis for what has happened.

In this connection, and emphasizing what seems to have been forgotten in considering Kirkland Lake and these eastern extensions, some of the Kirkland Lake producers had little or nothing at outcrop,—just a crack and low values. Kirkland Lake (and doubtless also this Quebec field or fields) required intensive exploring operations. Anyhow the Abitibi volcanics have a deeper meaning on the map, now than formerly and Quebec is to be congratulated upon developments.

Plenty of Ground to Play With

Ontario is accustomed to snowshoe staking throughout its silver and gold country. There is no need of this in the latest gold areas of Quebec. The Quebec Government will not record what has not been staked in accordance with the amended regulations to be promulgated. In bringing this about the Mines Department and Mr. Denis in particular, have rendered wholesome service to bona fide prospectors. Selective staking in the manner to be prescribed, is preferable to wholesale blanketting. Already it is realized that random staking is apt to be unremunerative to those concerned. The intrusive granites and porphyries are extensive. Basaltic occurrences are strongly developed. Enough ground is held by responsible people to engage the attention of field forces next summer. Meanwhile there is no hurry about blazing boundaries of what may not justify the cost. Porcupine and Kirkland Lake have supplied the object lessons. There are a small number of producers and a larger number of prospects deserving of development, but the useless claims outnumber many, many times those that give even a faint promise of becoming gold producers.

BIBLIOGRAPHY OF CANADIAN GEOLOGY

The Geological Survey maintains, at Ottawa, a bibliography of Canadian geology. This is an author index of the most important articles on Canadian geology published in periodicals, bulletins and transactions of scientific societies, and reports of various government departments, federal and provincial. It also contains references to papers written by Canadian geologists on geological subjects not connected directly with Canadian geology, and for recent years it is fairly complete. This bibliography is in the charge of Mr. Wyatt Malcolm, and may be consulted by the public. Readers of the *Canadian Mining Journal* are welcome to consult this index at any time they may be in Ottawa, and written requests for information from the bibliography will also be given attention. In writing for information the name of the author of the particular article wanted should be given, and in case the title of the article is not known some clue should be given as to its contents.

The Dominion Water Power Branch, Ottawa, estimates that the per capita consumption of coal in Canada for all purposes is only two thirds that of the United States, in spite of the colder climate. In industries and in the generation of electric power Canada's use of coal per capita is only two fifths that of the United States. The saving in our coal bill from the use of water power is approximately $146,000,000 annually.

The first National Exposition of Power and Mechanical Engineering will be held in the Grand Central Palace, New York, from December 7-13. Though designed essentially for mechanical engineers, it includes a large number of items of prime interest to miners. Among these items are exhibits and discussions on the following: Hydro-electric power; Cottrell electrical precipitator in action, the story of coal, petroleum, sulphur, asbestos, abrasives and natural gas, shown in moving pictures. There will be, of course, an extensive exhibit of prime movers, stopers, pulverized fuel apparatus, refractories, pumps, etc.

LETTERS FROM READERS

Mr. Campbell's Letter

Editor, Canadian Mining Journal:

Sir:

Mr. C. M. Campbell, whose remarkably well prepared letter appeared in your issue of November 3rd, is a close reasoner. His arguments are depressingly convincing. They are based, however, on assumptions that, to my mind, are not sound.

In assuming that bare statistics may fairly be used to indicate the relative importance of mining (or its relative unimportance) Mr. Campbell overlooks one or two very vital considerations. Mining perpetuates itself in myriad ways that are sometimes not easy to recognize. Accretions of wealth that orginated in Cobalt are now being used to develop pulpwood limits in Newfoundland, to finance land settlement schemes in British Columbia, to endow a Canadian University, and so on and so on.

All industries are interdependent upon all other industries. When Mr. Campbell attempts to isolate and examine mining as a distinct industrial entity, he is certain to do it less than justice.

In taking exception to Dr. Corless' permissible metaphor, I fear that I discern intellectual astigmatism on Mr. Campbell's part. When he demurs at Mr. Mickle's very mild adjuration, "Let us take a chance!" Mr. Campbell forgets the plain fact that the element of venture (and of adventure) enters into all business, from the corner grocery to the colossal modern industrial merger.

Mr. Campbell has enacted the part of a brake. A brake, suddenly applied, generates heat. Continued friction involves loss of power and destruction of material. Let us hope that one application will serve the purpose fully.

Let us hope, also, that Mr. Campbell, in mobilizing his formidable facts and figures, will remember that, while statistics are useful, clear vision is indispensable.

There is more danger to-day of mining being neglected than of its being overdone.

Yours etc.

J. C. Murray

Kingston, Ont.

The Canadian Collieries Explosion

The Editor, Canadian Mining Journal:

Sir,—On page 714 of the October 20th issue of the *Canadian Mining Journal* there is an article referring to a gas explosion in No. 1 Mine of the Canadian Collieries, Vancouver Island, in which 18 men lost their lives.

In this article, mention is made of a coal-cutting machine as being of a type approved by the U. S. Bureau of Mines.

The Sullivan Machinery Company advise that this was a totally enclosed machine of a type especially built for use in foreign countries and in Canada and differing in design from the Sullivan machines approved by the Bureau of Mines. The Company further advises that this equipment did not bear the Bureau of Mines approval plate, which identifies all permissible equipment approved by the Bureau.

Will you kindly publish this explanation, in order that any impression that this machine was approved by the Bureau may be corrected?

H. Foster Bain

Director, U. S. Bureau of Mines.

Kirkland Lake

NOTES ON SOME OUTLYING PROPERTIES

(By the EDITOR)

In both the major gold camps of Northern Ontario, a great deal of attention is being paid at present to properties on the outskirts of the principal producing areas, and the promising results of exploration, both surface and underground, on a number of these warrant the belief that the productive areas will be extended to a marked degree before the present impetus to exploration is brought to a standstill.

The Kirkland Lake field, particularly, gives signs of an extension eastward that will make it much more important to Canada's mineral industry than at present. The following notes concern a number of the prospects and near-mines of this area.

The Kirkland Lake road is now in first-class shape for motor traffic as far eastward as the King-Kikland property, in the centre of Lebel township, five miles direct eastward from the town of Kirkland Lake. From this main highway lesser roads branch out in all directions to the numerous properties that are under development. At this time of year, of course, the snow provides a good road almost anywhere.

Continental

The first of the outlying properties that one encounters is Continental, stretching for three miles a little north of eastward from the Kirkland Lake Proprietary, which is astride the Teck-Lebel township boundary. On the western half of the Continental ground, north of Gull Lake, a great deal of trenching and geological mapping has been done, and a vein over one-quarter mile long, of a good size and said to contain satisfactory values, has been uncovered. The rocks are those that contain the gold veins of the producing mines to the westward, and the facturing that is considered to have induced the presence of gold-bearing solutions is said to be in evidence throughout the three miles covered by the claims. By many it is considered that these claims cover the continuation of the "main break" in the Temiskamian sediments brought about by the intrusions of Algoman times.

There is a feature of the Continental development that is interesting and highly important, thought it has to do only indirectly with the property itself. Mr. Robert Bryce, who managed the acquisition of the property, arranged the terms direct with the owners of the numerous properties involved, most of these owners being the original prospectors and stakers. These terms were more generous than those usually accorded prospectors for their finds. Payments are now being made regularly as they fall due, and, as there are no middle-men with whom it must be divided, the prospectors are reaping the maximum of benefit from their labours. It is more than likely that a large part of the money thus disbursed to the prospectors will be re-invested in further prospecting—a direct result of sound and honest promotion.

Nipissing

To the south of Gull Lake at its western end, and within the band of Temiskamian sedimentary rocks, is the ground being explored by the Nipissing company of Cobalt. No official announcement has been made of the values got in the several diamond-drill holes put down on this property; but circumstances warrant the belief that the results have been at least encouraging. This work has been done on the southern, or subsidiary "line of break."

King-Kirkland and Bidgood

At a distance of four miles eastward from the Tough-Oakes shaft of Kirkland Lake Prop., the most easterly producing mine of the camp, lie the King-Kirkland, and Bidgood properties, on either side of Mud Lake. Both these properties are in good hands, and are being developed quietly and consistently, by means of sound financing and rational mining methods. The Bidgood, to the northeast of Mud Lake, is in charge of Mr. D. Angus, and favourable reports of its progress are issued periodically. The affairs of the King-Kirkland are in the hands of Mr. Fred Jordan. Drifting on the 400-foot level is in progress at present, with results that warrant the continuance of this expensive means of exploration.

Elsewhere in Lebel Township exploration and development to date either have disproved the existence of ore in paying quantities, or have been insufficient to form a basis for decision. The Bidgood and King-Kirkland promise to make mines.

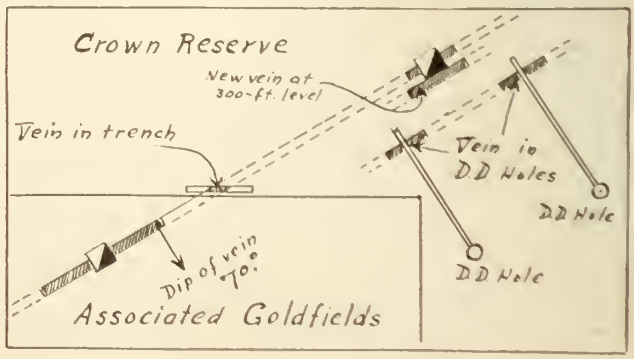
Gauthier Township

In Gauthier township, adjoining Lebel on the east, work is being conducted vigorously only on the Argonaut property, on Beaverhouse Lake in the northeastern quarter of the township. The Argonaut is a near-mine, and may make a mine. If it were not that the ore is somewhat refractory and that the vein is so badly faulted as to make mining development difficult and expensive, it is likely that the determined (though somewhat hasty and injudicious) attempt to put the property on a producing basis would have succeeded before this. As it stands, the good grade of the ore, when found, and the persistency of the vein in spite of faulting, may make profitable mining possible. The persistency of the owners in attempting to develop this isolated and somewhat inaccesible property deserves the highest commendation.

Elsewhere in Gauthier township comparatively little work has been done, and the value of none of the various prospects can be gauged with certainty. One of the most promising of the prospects is the Tobico, owned privately by Mr. George Tough of the Lake Shore mine.

Pancake Lake

The southern part of McVittie township, which adjoins Gauthier on the east (and thus is 12 miles removed from Teck township with its producing mines), covers part of the once famous and now notorious Larder Lake field. It is now known to contain, however, ore of the most promising veins of any of the outlying properties. The work of the Crown Reserve and Associated Goldfields companies at Pancake Lake, in the southwest corner of the township and



not far to the northwest of Larder Lake, has disclosed a vein not only continuous in extent, but so far as can be learned, containing high average values in gold. The vein is shown diagramatically on the accompanying sketch.

The vein strikes northeast, across the boundary line, and dips to the southeast at an angle of 70 degrees. It is visible on the Associated Goldfields property across a long stripping, on which a shaft is located. This shaft is now being sunk from the 350 to the 500-foot level according to announcement by the company. No information as to values or tonnage developed has been divulged.

On the Crown Reserve side, a trench close to the boundary showed the vein, with a good width and values. Four diamond-drill holes were put down last winter to intersect this vein, and they disclosed a vein with excellent values over a width of about twenty feet. The length of the pay-shoot has not been announced publicly. The shaft, now at a depth of 300 feet, cut another vein with good values half way down, and a second at the bottom, likewise with paying ore, neither of these two veins being visible at the surface. This property is being developed rapidly and economically under the direction of Mr. Harry Kee.

Ossian Township

Cornering on McVittie on the northeast is Ossian township, whose eastern side is on the interprovincial boundary in which there has been a recrudescence of interest since the sale of the Hurd-Fishely claims recently. The buyers are a New York syndicate, who have agreed to a price of $200,000, including a substantial cash payment. The showings on these claims, which are promising, are to be developed vigorously.

Twenty miles east of Ossian township is Rouyn township, to which the inevitable autumn rush has taken place. The existing maps show the geological formation of the gold field on the Ontario side to extend far eastwards into Quebec.

Zinc Business Conditions

DEMAND NOW RESTORED, AND OUTLOOK GOOD

BY KIRBY THOMAS

The world's production of crude zinc in 1913 was 1,117,417 short tons. Of this the United States produced 346,676 tons and consumed 295,370 tons. In the same year Germany produced 312,075 tons and Belgium 225,112 tons. A large part of the production of Germany and Belgium was exported. These figures represent the output of the smelters and do not take into account the source of the ore. The average yearly smelter production for the United States for 5 years prior to 1914 was 299,390 tons of which an average of 16,293 tons only was from foreign ores, mostly from Mexico and Canada. The greater part of the smelter production of Germany and Belgium, and of France and Great Britain (about 75,000 tons yearly, each) was from imported ores, mostly from Australia. Germany, however, had a considerable domestic production of zinc ore.

This gives a picture, in figures, of the pre-war zinc business of the world.

The war resulted in completely changing the picture. The restrictions on transportation prevented the utilization of the distant Australian ore, even to the extent of the limited smelter capacities in Europe controlled by the Allies. The Belgium smelters, except a few German-owned ones, were destroyed. The stimulus to the production of the United States was immediate and great. The smelter output of the United States in 1914 was 353,000 tons of zinc and attained a maximum of 669,573 tons in 1917. The production for 1918 was 517,927 tons, 1919, 561,713 tons, 1920, 163,377 tons. In 1917, 26,140 tons was from Australian ore formerly going to Europe, and 40,360 tons from Mexican ore. In 1921 the total smelter output of the United States was only 200,500 tons, practically all from domestic ore. This was less than the average for 5 years prior to the war by more than 80,000 tons.

These figures picture the war and post-war conditions in the zinc industry in the United States. The ore production and the metal and ore prices corresponded closely with these smelter production figures, naturally.

However, there were at no time any large surplus stocks of zinc in the United States and the supply of secondary zinc in Europe was small, compared with the secondary copper supply, and was mostly absorbed by the European demands pending the rehabilitation of the Belgium smelters and the restoration of ore supply from Australia and other countries. In consequence the zinc industry in the United States came back to a normal condition of activity very quickly with the general resumption of domestic business. Today the zinc production, demand and prices in the United States are above the average and the outlook for increased metal and ore production and high average prices is very good.

The tariff on ores on the new bill will exclude from the domestic market the cheaply produced Mexican ore and should stimulate the mining of zinc in the Missouri, Oklahoma and Wisconsin districts where zinc and lead are the principal products of the mines. In the western mines zinc is associated with lead, silver and copper ores and its production is dependent more on the general market for the other metals.

The increased demand for zinc as oxide for paint and chemical uses and for the making of rubber tires has opened a broad new market. Recently there has been an unusual demand for block zinc for the Orient, where it is used chiefly for galvanizing sheet iron to supply the demands of the new fire protection regulations introduced, especially in Japan. Part of this Oriental demand is now being supplied from the new zinc plant at Trail, British Columbia, which has been installed to treat the abundant rich ores of the western Canada districts.

The general conditions for zinc and zinc mining are greatly improved and the outlook for several years is good.

Tantalum and its close associate, columbium, are yet among the experimental metals — those which possess attractive properties but which have not yet been shown to have uses that some other and cheaper metal or alloy will not serve as well or better. With the number of new uses for the elements, their alloys and compounds that constant experimentation is developing, it is probable that for these metals also places will be found that they will fill better than any others.

Hess.

A New Process for Utilizing Feldspar

(Written specially for the Canadian Mining Journal)

For a number of years Mr. C. M. Brown, Toronto, has been working out the details of a method of treating feldspar in such a way as to make all three of its constituents oxides into commercially marketable commodities. His efforts have been successful to a degree never before obtained.

The results obtained by means of the Brown Process are of marked interest to the technical world and to Canadians generally. The operation of the process on a large scale will give commercial value to many feldspar deposits that are not now workable, and should ultimately make Canada more than self-sustaining as regards supplies of potash and alumina and their commercial compounds. The clean residue of silica that remains after treatment of the feldspar is saleable.

The process, details of which will appear at a later date, is simple and direct. It consists in the application of acid gases to finely ground feldspar, in a rotary kiln, at low temperatures. The disintegration of the feldspar is continuous and complete. The finished products are obtained by leaching and crystallization.

Theoretically potash-feldspar (orthoclase and microcline) contains 16.9 per cent. potash; 18.4 per cent. alumina; and 64.7 per cent silica. In nature, however, the potash content rarely exceeds 12 or 13 per cent., the alumina ranges from 17 per cent. to over 20 per cent., and the silica is usually higher than the figure given above. Only rare deposits of feldspar are pure enough to be suitable for use in the pottery and ceramic industries. Ordinary impurities do not affect its utility so far as the Brown Process is concerned.

The conversion of both the potash and the alumina contained in the feldspar into commercial staples is the outstanding feature of the Brown Process. The chemicals that are used either given a higher value by combination with potash and alumina, or are continously recoverable by the use of standard regenerative equipment. This, together with the avoidance of high temperature, keeps the costs down to a point where operating profits are demonstrable.

Canada is at present entirely dependent upon the United States for supplies of bauxite, the mineral from which the metal aluminium is extracted. Bauxite is also the source of commercial salts of aluminium, of which aluminium sulphate (common alum) is the most important. This salt is used in large quantities in the United States and Canada for the purification of municipal water supplies. There are numerous other uses for this and other salts of aluminium.

Bauxite is a mineral of varying and uncertain composition. As used for the manufacture of aluminium it contains from 44 per cent. to 52 per cent. of alumina, the average being about 45 per cent. It contains, as impurities, iron oxides and carbonates, silica, and titanium. The presence of these contaminants, of course, enhances the cost of treatment. It takes approximately 4.30 pounds of bauxite to make one pound of metallic aluminium.

By means of the Brown Process the 17 p. c. to 20 per cent. of alumina contained in potash feldspar can be converted either into aluminium sulphate, or partly into the combined sulphates of potash and aluminium, or partly or wholly into commercially pure alumina. In the latter form it would require less than half the quantity to make one pound of the metal aluminium as compared with the quantity of bauxite required. In addition to this, the product of the Brown Process is in every respect cleaner and more desirable.

About 600,000 tons of bauxite (the maximum output recorded for one year) is produced annually in the United States. Approximately one-quarter of this is used for chemical and other purposes. The remainder, representing about 115,000 tons of the metal, is used in the manufacture of aluminium in the United States and Canada, which together produce from 60 per cent. to 70 per cent. of the world's supply. Canada's output is about one-sixth that of the United States. As pointed out above, Canada is wholly dependent on the United States for raw material. Supplies of bauxite suitable for the production of metallic aluminium are becoming more and more difficult to obtain. A new source of alumina will change the whole character of the industry and will greatly strengthen Canada's industrial position.

Potash has never been produced in Canada in commercial quantities. Canada is bountifully supplied with potash-feldspar deposits. Despite long effort the United States has been unable to develop a domestic supply of potash. In Canada no serious attempt has heretofore been made to do so. Both countries rely upon imports from Europe. Potash, in various forms, is imported annually into the United States to the value of approximately $45,000,000. Roughly, Canadian imports amount to about a tenth of this sum. The development of a cheap domestic source of supply would increase enormously the use of potash fertilizers, and it may be noted here that from 80 per cent. to 90 per cent. of all potash imported is sold as fertilizers.

The residual silica, referred to above, has numerous uses in the arts and industries. It is believed that there will be no difficulty in disposing of it at a profit.

The results of Mr. Brown's preliminary work have been entirely satisfactory. A producing plant will be erected in the near future.

The manufacture of titanium pigments to replace white lead presents a possible, and promising, opportunity for expanding Canada's mineral industry. Some important experimental work is being conducted at present with a view to establishing on a commercial basis a process proved in the laboratory.

During 1921 China was the principal producer of tungsten ore in the world, obtained from placers for the most part. The famous placer deposits of Burma seem to be near exhaustion.

The use of molybdenum appears to be getting on a sounder footing than ever before, and the manufacturers who use it believe that as a toughener of steel it serves a real purpose when added to carbon steels in quantities reaching 03.5 per cent. It is used in automobile axles and springs and in shovels.

Even an undertaker is careful and believes in safety first. If you do not do as much he will get you sooner or later.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

POWER SHORTAGE.—The power situation in Porcupine is again complicated by the fact that the Power Company has had to reduce its output by 15 per cent. due to the burning out of one of the generators at the Sandy Falls plant. This has necessitated the different companies putting their steam plants into commission. The damage will probably not be repaired until some time in December, and the company has decided to keep the reduction in effect until the completion of the Sturgeon Falls plant, which is expected about the first of January. Rains and melting snow during the past week have eased the power situation and officials now believe there is plenty of water to carry them through the winter. It is understood that the Matachewan Power Company is making arrangements to enter the Porcupine field, and has already signed up the Davidson, which is controlled by the same interests as are behind the power company. The present development at Indian Chutes, on the Montreal River, is 2000 h.p., but plans are under way to increase this to 6000 h.p. The additional installation will call for an expenditure of approximately $800,000, which will be financed by an issue of bonds. It is understood that the power line from Matachewan to Porcupine will go by way of Night Hawk Lake, and will provide power to the Peninsular.

DOME.—Dome directors have announced a re-organization plan, which calls for four shares, of no par value, being issued for each share of the present company. It is also understood that no further capital repayments will be made, but that the dividend will be increased. No special reason is assigned for the proposed change, but it is understood that the lower-priced shares will command a wider market, and will be more satisfactory to use as collateral. At the present time there are 177,667 shares of $9.00 par outstanding. During October production was $482,712, as compared with $427,000 in September. The output for the first ten months of the year, however, shows a very substantial increase and amounts to $3,178,000 as compared with $1,822,000 for the corresponding period of 1921.

CLIFTON.—Directors of the Clifton Porcupine announce that as they are unable to obtain electric power at the present time they will install a steam plant of sufficient capacity to carry on milling operations. In the meantime the present steam plant is being utilized for underground development, which is understood to be giving satisfactory results.

MCINTYRE.—Of all the Porcupine mines, the McIntyre appears to be the one that is forging ahead most rapidly. Not only is development of the known ore bodies proving them up to expectations, but new discoveries have been made. In sinking the main shaft a new vein was found at a depth of 2100 feet, where it shows a width of about 12 feet, the values running much higher than the average of the mine. This is an entirely new discovery and appears to be extremely important. On the No. 7 vein drifts on the 1875 foot level have shown practically continuous ore for 1000 feet in length, which averages $20.00 across about 12 feet. There are strong probabilities that ore will be found over a total length of 2000 feet on this vein, and that it will be more important on the McIntyre ground than it was on the Hollinger.

DEVELOPMENT PROGRESS.—The Vipond has completed its shaft to the 1000-foot level, and is understood to have opened up a new ore body at that depth. The Porcupine Crown, in the same vicinity, is sinking a winze on the new vein discovered a few months ago, from the 500 to the 600-foot level. On the 500-foot level several hundred feet of drifting was done, where results were understood to be satisfactory. The Rochester has run a crosscut on the 100-foot level for over 300 feet and has cut a promising vein. Work has been stopped for the time being, due to shortage of power. Air was being obtained from the Hollinger Mine, but in view of the power shortage this is no longer available.

PROGRESS IN KIRKLAND CAMP.—Kirkland mines are again in full swing, and are in better shape than they were before, as during the enforced shutdown, due to power shortage, an opportunity was given to make changes which will result in more efficient and economical handling of the ore. The Lake Shore shaft has now been enlarged from the surface to the 400 foot level, and the company now has a three-compartment shaft to the 600-foot level. Work is being carried on at the 400-foot level, but the 600 is still under water. During September the mill treated 1716 tons of ore, averaging $17.98 per ton, and recovered $30,865. The ore was drawn from the surface stock pile while the enlargement of the shaft was being finished. Directors have declared a dividend of 2%, payable November 15th, to shareholders of record Nov. 1st.

PROFIT FOR TOUGH-OAKES.—The Tough-Oakes, after a long profitless period and very large expenditures, is once more on a profitable basis. September production amounted to $26,600, and it is understood that the profit realized was $5,000. While this profit was small, recent reports regarding mine development encourage the belief that soon it will be substantially larger.

WRIGHT HARGREAVES.—The Wright Hargreaves is again milling at the rate of about 200 tons per day. The new vein found in the shaft at 600 feet has persisted to 800 feet, which is the present depth of the shaft, and shows a width of about 6 feet and an average value between $12.00 and $13.00.

CONTINENTAL.—A large gang of men are doing surface work on the Continental property, and while it is understood that some veins have been encountered, no information regarding assays is available. The company is, however, building permanent camps.

KIRKLAND EXPLORATION WORK.—The Boston Kirkland has been secured by the Kirkland Hudson Bay Mines, and it is understood that operations will be commenced in the near future. Development on the Hudson Kirkland has been started, and the shaft will be sunk to 400 feet. Diamond drilling on the Highland Bay property is completed, and the company is now ready to [illegible] underground developments.

Montreal-Ontario—Directors of the Montreal Ontario have decided not to start milling operations until they have broken several thousand tons on the 450-foot level.

West Dome Lake—The annual report of the Hudson Bay Mines for the year ending last August shows revenue of $12,163 and expenditures of $19,739. The property was closed down most of the year. The Hudson Bay is a large holder of the Consolidated West Dome Lake, which is now resuming operations, and officials are hopeful that this may be a substantial source of revenue for the Hudson Bay Company.

Pancake Lake—The Crown Reserve has crosscut the main vein on the Pancake Lake property at a depth of 300 feet. It is expected that it will show a total width of about 20 feet.

Nipissing Bonus—Although Nipissing production fell off in October, due to two weeks shut-down, the company is in an exceptionally strong position and is making large profits. It is anticipated that a bonus will be paid with the January dividend, the same as was done in October.

Cobalt Shipments—During the week ending November 3rd, two companies shipped ore from Cobalt over the T. & N. O. Railway. The Mining Corporation shipped 489,000 pounds of residues and the Dominion Reduction Company, 87,000 pounds of flotation concentrate.

Fatal Accident—At the Herrick property in Shining Tree, which is under option to the Tonopah Mining Company of Nevada, three men were recently killed in the shaft, due to the cross-head falling. Inspector Bartlett, of the Mines Department, investigated and found that the cross-head was not equipped with the necessary safety devices, as specified by the Mines Act, and laid a charge against both the Tonopah Mining Company and the contractor in charge of the shaft work, which resulted in each of these being fined $500 and costs.

Bogus Stock Flotation—Unless something is done to curb the extravagant statements being made by the promotors of some of the newer mining flotations, Ontario is liable to have a Blue Sky law forced on it. The mining industry, as a whole, is in an extremely healthy and profitable position, particularly the gold mines. A great deal of public interest has been shown, and as there have been very large advances in the prices of gold shares during the present year, wild-cat promoters are trying to take advantage of it, and foist a lot of worthless stock on the public. Our present statutes, no doubt, are sufficiently broad to cover this matter, but, with the exeption of the *Canadian Mining Journal* and a couple of the financial papers, no one seems to be giving it any attention. This sort of thing hurts the legitimate mining industry, because with a large proportion of these stocks the purchaser has little or no chance of realizing any profit from his shares, while the legitimate mining industry is called upon to bear a part of the blame for the fraud.

NOVA SCOTIA

Disagreement within Union—There is a row of first-class dimensions in progress in the Nova Scotia district of the United Mine Workers between International and District officers. It appears that at the last meeting of the International Board Members held at Indianapolis, President Lewis asked Board Member Barrett why the Nova Scotia union was allowed to call out all the maintenance men, leaving the pits in danger during the August strike, after he had wired instructions to keep this class of labour at work. Board Member Barrett laid the blame on the District officers. Another matter President Lewis wanted made clear was that of the proposed union of District 26 with the third Socialist International. Both President Livingstone and Secretary McLachlan say that this is their own business. President J. L. Lewis disputes the point and may insist upon the repudiation of this connection with European extremists. If so, there will be "something doing" among Nova Scotian miners. It will be a pitched battle between those that uphold the U. M. W. constitution and those, like McLachlan, who want no restriction. We bet on President J. L. Lewis to win. He has both Cumberland and Pictou counties with him to begin with, and a host of quiet, thoughtful men in Cape Breton. If the quarrel develops, the coal companies would be well advised to keep out of it until it begins directly to affect their interests.

Mr. Wolvin's Tour of Inspection—While President Wolvin said very little on the occasion of his recent visit of inspection to the steel works and collieries of Nova Scotia, the changes that have taken place since then are indicative of a very searching inquiry into the state of the British Empire Steel Corporation's practical affairs. Whether he found things to his satisfaction, no one here seems to know. Evidently we are in for a "shuffle." Mr. E. P. Merrill, general manager of the steel works, has been transferred to the steel sales department in Montreal, and other changes will follow. While no one has been appointed yet to Mr. Merrill's late position, the name of Mr. F. W. Gray, assistant to vice-president MacDougall, is commonly mentioned. Should Mr. Gray be appointed to this position, it will meet with general satisfaction not only here in Nova Scotia, where he is known and respected by all, but throughout Canada, where his unusually clear grasp of the coal situation has brought him prominently before the public notice.

BRITISH COLUMBIA

Granby—Operations of the Granby Consilidated Mining & Smelting Co. are to be quite extensive in the Portland Canal District of British Columbia this winter. The Company has taken over, in addition to the Outsider group situated on the Canal, the Sunshine property on Glacier Creek. On the latter it is the intention to do a considerable amount of tunnel work. With 200,000 tons of ore (according to report) already blocked out on the Outsider it is confidently expected that development of the mine with a strong crew of men will continue in the spring.

Salmon River—Pat Daly, veteran mine operator, has taken a bond on the Yellowstone group in the Upper basin and proposes floating a company to take over and develop the property.

Portland Canal very Active—It is anticipated that work will proceed on some 12 or 13 properties in the Portland Canal District this winter. Nine of these are on the Salmon River, four of which, the B.C. Silver, Indian, Big Missouri and the Premier, are on the British Columbia side, while the other five, the Fish Creek property, being operated by the American Mining & Milling Co., the Titan, Riverside, Daly Alaska, and Alaska Premier are on the Alaskan side of the boundary. There are six active properties on the Bear River, viz., the Prince John, the Dunwell, Sunshine, Mimico, Mobile and the

Silver Bell. The Idaho on the Marmot River also is being worked. Two of those mentioned, the Sunshine and the Outsider, the latter situated on the Canal, have been taken over by the Granby Co. The same Company has acquired the George group on the Bear River which it is the intention to develop extensively. On the majority of the properties referred to, with the exception of the Premier Mine, where some 225 men are employed, the average crew members about 10 men. The American Mining & Milling Co. on Fish Creek, however, have a larger force engaged and are looking forward to making regular shipments of high-grade ore over the snow. The activity of the Granby Co. in the Bear River section has given rise to speculation as to the possibility of opening up the Portland Canal Railway. If a sufficient tonnage of ore were assured to warrant this it would mean the more rapid development of many promising prospects.

W. G. Norrie Lowenthal, Mining Engineer, has been inspecting some mining properties in the Alice Arm and Hazelton Districts, Northern British Columbia.

A Nelson Prospect—Mrs. Kate McAvoy, the woman pioneer prospector of the Kootenay, reports that the Taft group at Erie, near Nelson, is developing satisfactorily. Two tunnels have been driven, one running southeast for 100 ft. and the other due west 80 ft. She states that in the former the values run up to $61 a ton in gold over a width of 3 feet, while the lower tunnel shows consistent value of $18 a ton.

Mine Taxation—Representations are being made to the Provincial Government for some changes in the Taxation Act in so far as it is applied to active mines. A short time ago a delegation met the Hon. John Hart, Minister of Finance, on behalf of the Britannia, Granby and Surf Inlet Mining Companies. It was claimed that some more equitable system might be adopted in the assessment of such mining properties as those enumerated. It was pointed out that at present provision is made for a gradual reduction of the assessment as the mineral is recovered. The deputation was assured that the matter would have careful consideration.

A meeting of the Mine Owners' Association of the Interior of British Columbia was held recently at Kaslo, when a resolution was passed urging that in the taxation of mines more consideration be given to the depletion of values in the course of mining. Messrs. Randolph Bruce and T. J. Bragg were appointed to meet the Hon. Mr. Hart and outline to him the views of the association. The annual meeting of the Association is to be held on December 6th at Nelson, B. C.

A Sandon Prospect—A 2-foot vein of ore has been uncovered on the American Boy at Sandon. A small force has been working on the property for the past couple of months under the foremanship of John Vallante under whose guidance the Standard Mine at Silverton was developed to the shipping stage.

Copper Star, Nelson—Optimistic reports are being received regarding the possibilities of the Monarch group of mineral claims situated at Beasley on the south slope of a mountain rising from the Kootenay River and about 9 miles west of the city of Nelson. M. P. McDonald recently examined and has submitted a report on the property, which indicates that it has every chance of becoming one of the big copper producers of the west. In brief it is stated that the development to date indicates that there exists a mineralized zone of at least 1000 ft. in width, northeast by southwest with a strike northwest by southeast, crossing three full claims of the Monarch group. Mr. McDonald's sampling shows returns of about $13.80 a ton. The property is well situated, being close to the water, within easy reach of the Trail Smelter and having near at hand the power of the Kootenay Power and Light Co. It is understood that capital now is being obtained with a view to pursuing further development.

Trail Ore Receipts—For the last ten days of October the ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co. aggregated 12,011 tons. Three new names appeared among the independent shippers, viz., the Meteor and Hampton both of Slocan City, with 12 and 23 tons respectively, and the Atkins of the Republican Camp, Washington, with 44 tons. Other shippers over this period were Alamo, Alamo 44; Forence, Princess Creek 95; Knob Hill, Republic, 110; Quilp, Republic 323; Rambler-Cariboo, Rambler 35, Standard, Silverton 417; Silversmith, Sandon 308; Sally, Beaverdell 35; Whitewater, Retallick 27; Company mines 10541. This brings the total receipts at the smelter up to the end of October to 351,078 tons, which is considerably in excess of the average of past years.

Britannia Power Contract—A contract has been entered into between the Britannia Mining Company and the B. C. Electric Railway Co. under the terms of which the Railway company is to supply from 1500 to 6000 horse power for mining operations of Howe Sound. A high tension line will be built immediately from North Vancouver along the Coast to Britannia, a distance of 30 miles at a cost of $150,000. It is stated that the Britannia Company decided to adopt this method of obtaining power for the reason that lack of water at certain seasons made it necessary to consider the building of extensive storage works in order to assure the continuous operation to the mining plant now in course of installation. The alternative was to acquire the power of the B. C. Electric and as the contract has been signed it may be assumed that it was found this more attractive both as to service and as to finances.

B. C. Iron Steel Plant—The project of the establishment of an iron and steel industry in British Columbia at present is in abeyance. One third of the cost was to be covered respectively by the Imperial, Dominion and Provincial authorities. Hon. T. D. Pattullo, Minister of Lands, returned a few weeks ago from England and is quoted as saying that the political upheaval there is likely to interfere with negotiations.

NEW DOMINION REPORT ON COAL

A comprehensive review of the coal industry in Canada, covering the three years 1919-20-21 is given in a report issued this week by the Dominion Bureau of Statistics. The solution of Canada's coal problem depends in no small measure on the availability of reliable information on the subject and the report just published, containing 116 pages of tabular matter showing in detail the output by collieries, the imports of coal by ports of entry and the exports of Canadian coal, will do much to meet this need. Several tables are given descriptive of the organization and progress of the coal mining industry with particulars regard to the capital investment, plant equipment, men employed, time worked and tonnage lost. The report contains a chapter in which the Dominion situation is reviewed and there are also separate chapters dealing with the industry of each of the coal producing provinces.

It is pointed out that the apparent consumption of coal

in Canada varies between 30,000,000 and 35,000,000 tons annually, of which approximately one-half is imported from the United States. Canada exports between 2,000,000 and 2,500,000 tons of coal each year. According to the report there were 396 coal mines in active operation in Canada in 1921 working over an area of 713,000 acres.

The total capital invested in the industry at the close of the year was $176,991,495, of which $77,000,000 was invested in Nova Scotia; $53,000,000 in the mines of Alberta; $41,000,000 in British Columbia; more than $3,000,000 in Saskatchewan and over $1,000,000 in New Brunswick.

The coal mining industry in Canada gives employment to approximately 30,000 men and the wage bill for 1921 amounted to $42,758,471. In addition to this amount $3,717,238 was paid to salaried officials numbering about 1,600 in all.

The report is the most comprehensive review of coal statistics that has been published by the Dominion Government. Copies may be had, free of charge, on application to the Dominion Bureau of Statistics, Ottawa.

The Sullivan Machinery have just issued Bulletin 70-Y describing Sullivan Valveless Stoping Drills. These Stopers are available in two patterns, light weight hand rotators, dry or water, and automatic rotating machines, either dry or wet type. The automatic rotator is equipped with a new air throttle control of the admission of the air to the feed cylinder, by means of which the advance of the drill is retarded to suit the requirements of drilling, or stopped entirely, as in spotting a hole, passing through a vug or on striking softer ground, by merely pressing a lever attached to the main throttle. The water drill of this type has one throttle for air and water and discharges the water jet through the hollow drill steel at the back of the hole to lay the dust of drilling.

40,000 TONS OF COAL REQUIRED TO MAKE ONE OFFICE BUILDING

In an address in Washington last week, Dr. George Otis Smith, Director of the Geological Survey, gave his audience a graphic description of the importance of coal to our modern civiization. He instanced the modern office building in which the Coal Commission has its offices. From observation of this particular building while it was going up, a rough formula has been deduced that can be applied to almost any modern office building, as follows: Take by weight 60 parts of gravel, sand, and crushed stone, 58 parts of tile and brick, 27 parts of building stone, 19 parts of cement, and 16 parts of steel, with much smaller proportions of copper, glass, asbestos, paint and tar.

Yet there is another mineral ingredient that enters into every one of the building materials, an invisible but essential component of the structure -the coal that helped to quarry and dress the stone, to smelt and fabricate the metal, to burn the cement and tiles and brick. And while the formula calls for 27 parts of stone, the most conspicuous constituent of the building, it had been necessary to use nearly three times as much coal to produce all those raw materials and make them ready. Nor is this structural coal—37,000 tons of coal for the Interior Department Building— the whole of the contribution of coal, for it took perhaps another 3,000 tons of locomotive fuel to assemble all these mineral products from mine and quarry and fabricating plant, for no less than 22 States contributed the structural materials that went into this Federal building in Washington.

This is typical of the material side of modern civilization. Truly, it is dependent to a degree that few of us have realized upon that common, dirty, and now costly bit of earth's crust — coal.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertiserswill be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eigthpage, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale,Que., who can in all probability, refer them to proper sources.

EDITORIAL

It is well that outsiders should know that the [Canadian Mining] Institute is not for the benefit of speculators or mining manipulators, but was established, and is maintained, for the advancement and protection of the genuine mining interests of the country. — *G. R. Smith* — 1907

THE INSTITUTE'S USEFULNESS

Inertia is the worst foe of progress. In certain respects the Canadian Institute of Mining and Metallurgy has become inert. Therefore the current discussion on "Institute Policy" has much more than its intrinsic merit. Even for its own sake, however, it deserves the closest attention of those members who have a genuine interest in their Institute. By their active participation in the discussion, or by the attention with which they follow the progress of the debate, can the true interest of members in the Institute be gauged.

In his paper on "Institute Policy" read before the Western Annual Meeting in Vancouver last week, Mr. Mackenzie provides concrete proposals and definite statements round which a fruitful discussion can be made to centre. We print today his summary of the paper, with the Institute's charter appended.

While we agree heartily with Mr. Mackenzie in his determined effort to secure for the Institute a definitely formulated "forward policy" that will call for continuous and constructive effort on the part of members, and while we are convinced, as he is, that the Institute must retain its original status as representing Canada's mining industry, still we differ from him in some of his deductions, and would map out a somewhat different course of action for the years to come.

There is no doubt that the Institute can do most for the progress and final direction of the mining industry by continuing to be its public representative. This was the chief cause of its creation and constitutes the keynote of its charter. The charter wisely provides latitude for expansion and ramification by means of by-laws consistent with itself. The founders of the Institute claimed no extraordinary prevision, and formulated in the charter only a broad policy, which is sound now as then.

During the quarter-century of the Institute's corporate existence the practical direction of Canada's mining industry has passed gradually into the hands of technically trained engineers, the bulk of whom are now registered as Professional Members. The professional conduct of these engineers, and accessions to their ranks, are subjected to no systematic scrutiny and are subject to no control outside the purely formal addition of their names to the Institute's list of professional members. This is not as it should be. Mining engineers deserve a status in the general community that they do not possess at present. They can gain this status only by the concerted effort characteristic of a professional society. They must have this society.

Mr. Mackenzie assumes that, in order to effect this end through the agency of the Institute, its status must be changed from that originally intended to that of a purely technical society. We do not agree. There is an alternative, which we have pointed out before in these pages. The present section of Professional Members, already constituted, can be made to serve all the legitimate purposes of the technical society without interfering at all with the general aims and activities of the Institute. If there should arise a conflict in the aims of this section of the Institute and those of the general body of members, then there is available immediately the means of settling the dispute. It were far better to have the two classes of representatives of the industry in intimate contact and, in general, working unitedly toward their common end than to have two bodies in separate organizations.

This solution of the problem disposes of the objection that technical status is contrary to the intention of the charter and the charter members. The charter expressly provides for developments such as we have proposed, by means of by-laws. We hold that "to encourage and promote these [mining and metallurgical] industries by all lawful and honourable means," it is now expedient to regulate the practice of mining engineering by means of an association of Professional Mining Engineers. The Institute offers an immediate and effective means of doing this.

To conduct effectively the affairs of such a professional association will require much more than the scant ten dollars now paid annually by members of the Institute. It will be worth more. At present [illegible] worth little or nothing to be enrolled as a Professional Member. As soon as these Professional Members shall have been constituted into an active professional association, professional membership will be worth a fair

ther sum. Thus ean the proposed activities of the professional section of the Institute be supported without imposing a financial burden on the parent body.

As for the seope of the Institute's activities when an active section of Professional Mining Engineers shall have been inaugurated, it is obvious that it will inelude all that is in prospect now, with the addition of the provisions that are advocated so ardently by a large number of Western members. Our present proposal is, so far as the Institute is concerned, eonstruetive and not restrietive.

This is not a new idea. It is the idea that impelled the movement for the registration of professional members in the first plaee, years ago. The idea has, meantime, been lost sight of. We wish to bring it into view once more.

LAKE ST. JOHN AS ELECTRO-METALLURGICAL CENTRE

The mooted development of the huge water power where Lake St. John diseharges into the Saguenay River brings to mind the question of how the power resources of the Lake St. John district, which constitute one of the principal natural resources of that district and form one of the largest undeveloped sourees of power on the continent, are to be made a source of income. The smaller and more easlly developed falls of the neighborhood will always be suffieient to serve the needs of the pulp and paper industry and of the normal urban eommunities. Unlike Shawinigan Falls, it is too far removed from any industrial area in the United States to allow of the profitable export of power. There is at present no warrant for the belief that general industrial activity of suеh dimensions as to require a million horsepower will ever be centred round Lake St. John or the Saguenay, or even round Quebec, whither the power could be conducted economically. It would seem that electro-metallurgy must remain the chief reeourse for its use.

The principal raw materials in electro-metallurgical processes are minerals. Coke and limestone give ealcium carbide, acetylene, acetic aeid, acetone, and a host of derivatives, including eordite when neeessary. Quartzite is the basis of ferro-silicon manufaeture in the electric furnace, and magnesite of metallie magnesium. There are a number of such processes well established, that are available for industrial applieation where conditions are right. Cheap eleetric power is the essential condition. Other processes wherein eleetricity either replaces another form of energy formerly used, or makes possible the production of a new material, are being evolved with remarkable rapidity. It seems probable, for instance, that the economic production of electrolytie iron and sulphur from pyrites will be accomplished within a short term of years. So the possibility of utilizing the Lake St. John power in large amounts is growing rapidly.

The Lake St. John district has been explored for minerals in only the most desultory way. The chief resource disclosed so far is titaniferous iron ore, which is available in amounts far in excess of the quantities suggested in reports by the Quebec government. Large deposits of feldspar have been loeated along the upper Saguenay river, and there is no doubt that vast amounts of this mineral would be disclosed were there any incentive to a thorough search. Limestone, of a sort, and clay are available along the south shore of the lake.

With its abundance, or indeed superabundanee, of water-power, its seaport hard by at Chieoutimi, and its routes of travel radiating from Lake St. John and the upper Saguenay, this district is a most attractive one for eleetro-metallurgieal development, though this development may be delayed until power near the front is in use and until the prospeetor's searеh diseloses mineral deposits that will eomplete the list of natural resourees required.

A TAX ON PUBLIC RESOURCES

"At the present time [coal] mine workers are receiving a seale of wages far above that paid in other industries, with the result that the workers in these other industries are paying tribute to the mine workers. Continuation of suеh a condition cannot fail to have disastrous results upon the anthraeite industry, and therefore upon those employed in it."

In these words do the General Committee of Anthracite Operators of the United States epitomise the fundamental fact of the relation of their industry to its workmen and of both to the public. These two sentences are part of a preliminary statement to John Hays Hammond, chairman of the United States Coal Commission, in response to his invitation to submit data and suggestions, which we published in full on November 3rd. These leaders of the anthracite industry are unequivoeal in their denunciation of a condition that is eeonomically and morally unsound. This unsound eondition affeets Canadians in almost the same degree that it does Amerieans. We are paying tribute alike.

The statement of the anthraeite operators is an admirable document, broad in its scope and lucid in its presentation. It does not, of course, discuss the ways and means whereby the consumers of anthracite coal are compelled to pay tribute to them, (the operators). That question is left discreetly in the back-ground. We hope it will be brought into the centre of the picture before the Coal Commissiou's activities are ended. But the operators' committee have done a distinct service in pointing out so clearly the fact that the anthracite miners are even now a parasite class in the community, since they receive for their labour more than they earn.

This question of the wages paid to anthraeite miners touehes the majority of Canadian householders very

nearly at present, since they depend upon anthracite fuel. We hope it will be of much less concern to them within a short term of years, when Canadian sources of domestic fuel will have been developed and used more largely. But the general problem of specially paid classes of labour, subsidized at the expense of all others in the community, will remain. Within our borders, the case of bituminous coal miners deserves our immediate attention.

At present the coal miners of Canada, both east and west, are receiving all they earn—in some cases in the west, possibly more than they can earn. The daily rate of pay in the east does not need to be so high as in the west, both because of the differing values of the dollar in the two localities and because the Nova Scotia miner is able to work more days in the year than the westerner. So long as the western miner's inability to do a full year's work is beyond his own remedy, his partial support by the rest of the community is his due. But it would be wise for the consuming public, thus forced to bear the financial loss due to seasonal mining of coal, to examine the case carefully, to see whether or not this expense can be avoided.

Three weeks ago we pointed out that the executive of the miners' union in Alberta, had given notice of a demand for a six-hour day and a five-day week. Since then the executive of the miners' union of Nova Scotia has followed suit. How far these United Mine Workers' officials are backed by the rank and file of the miners, and what part of their demand they expect to enforce, we have no means of finding out. It seems possible if not probable that the demand is in the nature of a manoeuvre. Nevertheless the fact of the demand demonstrates a point of view that not only contravenes the dictates of justice, but is in direct opposition to the principles of democracy. Our population in general is already paying a very heavy tribute, in the way of excessive and unearned wages, to the organized railway workers and a number of lesser classes of unionized labour. Let us see to it that those who mine our coal are not added to the ranks of those licensed to draw more from the common fund than they put into it.

EDITORIAL NOTES

It has been proposed recently, and at intervals before that, to abandon the publication of the Annual Transactions of the Canadian Institute of Mining and Metallurgy in favour of the monthly periodical. It is interesting to note in this connection the complete statement of "objects" in the original constitution of the Institute. They are (as published in the volume for 1897),

(a).—The publication in one volume of the papers and proceedings of the organizations of the federation.

(b).—Action upon such matters affecting or relating to the mineral industries of Canada which may be referred to it by the societies in the federation. It may be noted that the national Institute was inaugurated as a federation of several provincial mining societies.

Excitement grows apace in oil circles as the first of the wells in the Contts-Sweetgrass area of southern Alberta nears its goal. High hopes are founded, with substantial warrant, on what this area will disclose. We hope that, in case a flowing well should result, investors of all degrees will keep their heads to a reasonable extent. The ground round about that gives even the slightest promise is already being held in anticipation of a successful outcome.

The glaring, and obvious, advertisements of shady and bogus mining shares have decreased to a remarkable extent during the past week or two. We hope that all the activities of those who paid for these advertisements have been curtailed in like degree. It is highly satisfactory that the Ontario government is to make a serious attempt to enforce the laws against the sale of illicit mining stock.

THE LYE DIRECT

(That epileptic fits can be simulated by the simple expedient of masticating a little soap, is a matter of common knowledge. In the painful episode hereunder narrated, without colour, the chief actor involuntarily gave a practical demonstration of the efficacy of soap in this respect.)

Out in a Western mining camp
The shift-boss gets an awful cramp.
He hustles to the cookhouse, where
He starts right in to cuss and swear.
He asks the cook for something hot;
The cookee grabs a great big pot,
And ladles out a cup of stuff
That looks like it was strong enough.
The shift-boss swallows it right off,
And then begins to gag and cough;
And then he yells for drinking water,
His eye plumb full of blood and slaughter.
The second he takes water in
His serious troubles sure begin:
For bubbles, large and small, by Jim!
Starts rippin', rushin', out of him.
Bubbles as big as footballs came,
They's others will confirm that same.
It takes about a hour or so
Before them bubbles cease to blow.

* * *

It turns out, after some enquiry,
(In which the shift boss acts some fiery)
That cookee has mistook his dope—
He's served the shift boss hot soft soap.

Letters From Porcupine--III

WITHIN THE CHARMED CIRCLE

There is much that points a moral and adorns a tale in the recent history of the Rochester claims, which abut the Hollinger on the northwest corner of that property, and lie immediately to the east of the town of Timmins. After the Nipissing syndicate had given up their option on the Rochester, it became more or less of a drug on the market. It required a certain amount of courage to resume work on an abandoned property, especially in the face of the ill-concealed antagonism of the major gods and godlets.

However, Mr. F. C. Loring, than whom there is no more consistently cheerful taker of fair mining chances, took matters in hand last summer and interested English capital (good sporting capital it is) in the development of the Rochester.. In the working arrangement entered into Mr. Loring and Mr. "Tom" Flynn were prime movers.

Sinking was stated on August 2nd. Early in October the shaft was down 110 feet, and a cross-cut from the 100-foot level had been driven 130 feet south to cut veins whose existence had been proven by diamond drilling.

The shaft was started in typical basalt. At a depth of 70 feet the characteristic Porcupine schist was encountered. At 90 feet a 10-foot quartz vein, having the same dip as the schist, 70° N., was cut. At about 150 feet south in the cross-cut a vein showing much visible gold came in, contrary, I believe, to the expectations of any but Messrs. Loring and Flynn and two of their coadjutors. What has happened since then I do not know. I have written this to show that spirited and intelligent exploration is almost bound to be rewarded in the long run.

The British Porcupine Development Company, which is Mr. Loring's concern, controls 52 40-acre claims scattered pretty well all over Tisdale township. In addition to the work being carried on at the Rochester, the company has three diamond drills at work at widely separated points. A "strike" on any one of the numerous properties controlled by the company will justify the expenditure on all.

This, I think, is an excellent example of well-directed prospecting. Every week and every day of progress heightens the chances of success.

I believe that the *Canadian Mining Journal*, if it will forego preaching for a jiffy, will join with me in wishing all success to this venture.

* * *

In one point there is uniformity in milling practice in the three large plants of Porcupine. Precipitation of gold from cyanide solution is effected in all three plants with zinc dust. At the McIntyre mill zinc boxes were given a trial and were quickly abandoned. In all three mills lead acetate is used to aid precipitation.

There is wide divergence in refining methods at the three plants. At the Hollinger the raw precipitate is smelted in blast furnaces; the bullion is brought down with lead; the lead is driven off in standard cupellation furnaces, and a bullion of 950 total fineness is obtained.

At the McIntyre the raw precipitate is treated with sulphuric acid and melted in a carborundum-lined, tilting, reverberatory furnace. The bullion here is brought to a total fineness of 900.

The practice at the Dome consists in treating the precipate with sulphuric acid, calcining and melting in small clay-lined graphite pots in a reverberatory furnace. The fineness obtained is from 990 to 995.

All this is a wonderful and fearful contrast to the refining carried on in the old-fashioned stamp mill. I can well remember pouring water over the neck of the old mercury retort, also the unpleasant symptoms of incipent salivation.

It is likely that the roar of the stamps, by the same token, will be a forgotten sound in Porcupine within—well—say, a short time. That's vague enough to be perfectly safe. But the stamp is an illogical and power-wasting contrivance at best. It is a strange and anomalous survival. In the last ten years it has lost much face. Experience at Porcupine has contributed not a little to the stamp's approaching relegation to oblivion.

* * *

Referring again to Porcupine milling practice, some incidental changes in the flow sheets are extraordinarily interesting. For instance, the use of Hudson's Bay blankets on the lower ends of amalgamating plates at the Dome mill was a distinct improvement. In due course of time these costly items were superseded by a cheaper and more suitable material, wide strips of "silent felt" the stuff in common use between the linen tablecloth of civilization and the mahogany table.

Another instance is afforded by the supersession of pebble grinding at the McIntyre by the use of steel slugs in the place and stead of the pebbles. A slight increase in cost was compensated for by greater tonnage and a much more uniform product.

Another change in practice at the McIntyre resulted in reducing the consumption of zinc from 0.20 pound per ton of solution to 0.05 pound per ton of solution.

Other instances almost without number could be cited. They all go to show the well-nigh priest-like devotion of the mill superintendents. The simile would not hold for a minute if the reader could hear some language that I have heard when all is not well with the mill.

J. C. MURRAY

TITANIUM ALLOYS

To Canada, with a large part of the world's available titaniferous iron ore within her borders, developments in the uses of titanium are of considerable importance. The uses so far determined consume only a comparatively few tons a year of titaniferous ore, the chief of them being "magnetite" electrodes for arc lamps, in which ground ilmenite is admixed with other ingredients, and ferrocarbon titanium, used to an increasing extent to de-oxidise and de-nitrogenise steel in the ladle just previous to casting. Titanium has a marked affinity for these two elements, and it is found that the resulting particles of slag are so highly fluid at the temperature of the molten steel that they rise immediately to the surface, coalesce, and are removed.

The Bureau of Mines, Washington, has published a bulletin, serial number 2406, "Titanium", describing the titanium alloys at present in use, ferrocarbon titanium, ferrotitanium, cuprotitanium and manganotitanium. It can be had on request.

Institute Policy*

..SUMMARY OF PAPER BY G. C. MACKENZIE..

In presenting a summary of my paper entitled "Institute Policy," I would ask for discussion of the following points:—

(1) *For what purpose was the Institute organized?*

The Institute was organized for the service of the allied industries rather than for the service of the allied professions. I submit that the Charter (our constitution) contains no clause relative either to the service or to the qualification of members and, therefore, neither the personal benefit nor status of members is provided for by the Charter. I also submit that the first clause in the Charter cannot be considered the most important clause simply because it happens to be the first. If, as it is claimed, precedence denotes importance, then we must conclude that the maintenance of a central reference library is of more importance than the encouragement and promotion of the allied industries, which is absurd.

We may, therefore, conclude that the Institute was organized in the service of the allied industries and was to be composed of persons who were interested in the promotion of these industries.

(2) *Is it possible for the Institute to acquire technical status under its existing Charter?*

The election and classification of members is controlled by the By-Laws. The first By-Laws adopted in 1898 were drawn up in conformity with the ideals expressed in the Charter and contained no reference to the classification or grading of members. These By-Laws have been amended from time to time by an active minority who, losing sight of the fundamentals expressed in the Charter, have attempted to give the Institute a measure of technical status. Admitting that this active minority has been actuated by the highest motives, it nevertheless was attempting constitutional changes without the necessary formality of amending the Charter. We have now reached a point where the first By-Laws, drawn up in conformity and in parallel with the Charter, have been so altered that the original parallelism is destroyed and the ideals of the founders, as expressed in the Charter, are in danger of being lost altogether. Therefore, the attempts at grading membership with the view of acquiring technical status, under the existing Charter, may be described as a process of veneering, because there is no established constitutional foundation upon which such grading could be based.

(3) *Are the ideals of our founders, as expressed in the Charter, of sufficient importance to be retained and upheld?*

To contend that what the founders had in mind in establishing the Institute is unimportant, is to admit that the meaning of the Charter is of no consequence to us and that we are now out of sympathy with the objects of the founders. If we *can* adopt that attitude, the way is clear and we may proceed to change the Institute constitutionally so that it shall become a professional organization possessing, in time, a definite technical status. But it is believed that the majority of members are *not* out of sympathy with the ideals of the founders, and that they *do* value the historical record of the Institute in so far as it has given expression to those ideals.

(4) *What can be expected from re-organizing as a professional society?*

In the first place we may expect that the total number of members forming such a society would be less than half the present membership of the Institute, because the number of professional men presently engaged in the mineral industry of the country is approximately half the present membership roll, and it cannot be assumed that all of these men would support a strictly technical society.

In consequence of this reduced membership, and because the functions of such a society would be limited to ideals of professional duty, the annual revenues, unless augmented by increased membership dues, would be absurdly small.

We know that it has cost the Institute annually an average of $13.40 to carry each member through the twelve years 1910 to 1921, and we also know that members have averaged an annual contribution of $8.18 in dues, toward that expense.

The number of members contributing dues throughout the twelve years averaged 1024 yearly. It is, therefore, obvious that if we reduce the number of members we must increase the dues of each member if the Institute's expenses are to be met.

The difference between the average annual cost per member and the average annual contribution per member throughout the twelve year period was $5.22. This amount accrued annually to the Institute as the result of activities apart from the performance of any professional functions. If, then, we limit the functions of the Institute to the service of the professions we may expect that revenue from sources, other than annual dues, will decline. It will, therefore, be apparent that if such a re-organized society is to apply its revenues in the service of the professions on a scale approaching the past activities of the Institute, its schedule of dues must be considerably higher than the present annual dues of the Institute. Taking all factors into consideration, I submit that annual dues of not less than $25.00 would be required.

The principal function of such a technical society would be the holding of meetings for the reading and discussion of papers and the furtherance of acquaintance and goodwill among its members. Bearing in mind the small membership and with appreciation of the size of the country and the distances separating our mining centres, we may feel confident that these meetings would be characterized by a very limited attendance.

If the re-organization of the Institute on a technical basis is to result in largely increased dues and poorly attended meetings, the Institute will have sold its birthright for the expensive luxury of [illegible] expensive in more than one sense. [illegible] cannot qualify for membership, and [illegible]

*Published in full in November issue of Monthly Bulletin of the Canadian Institute of Mining and Metallurgy.

will be quick to see the significance of class motive and will look upon such a re-organized society as a close corporation, a society that places service to its members before the service which it owes to the industries that gave it birth.

(5) *What can we accomplish by amending the By-Laws in conformity with the Charter and adopting a national and democratic policy that places service to the allied industries before all else?*

There are many things which the Institute should strive to accomplish in the service of industry. The holding of meetings at which all component sections of the society may be represented; the equipment and maintenance of divisional machinery; the prompt printing of all Institute papers and the distribution of information concerning our mineral resources through the medium of the Monthly Bulletin. These are a few of the duties of the Institute, and yet we find that but one of them, the printing of the Monthly Bulletin, is beyond our resources at the present time.

The membership roll of the Institute has grown at the rate of 45 members per year during the twelve years 1910-1921.* This laborious and painfully slow growth has been due to either one of two things, (a) A narrow and restrictive policy or (b) An industry too weak to support a larger membership.

Our industry is not weak; it is comparatively young and subject to many of the ailments of youth, but, compared with other basic industries of the country, we know that it occupies a position second only to agriculture. Therefore, the only logical conclusion is that we have been following a mistaken policy.

By amending the membership By-Laws so that they shall again conform with the purpose of the Charter, the Institute will have demonstrated that it still holds to the ideals of its founders and is no longer to be swayed by motives of class interests. We shall then, *with all honesty*, be able to say that the society welcomes every class of reputable citizen to its ranks, not because of any personal benefit that may accrue to them, but because of the opportunities offered by aiding and stimulating industry through the medium of Institute membership.

Having taken that step, the problem of increased membership will solve itself, and with increased membership will come, in time, the ability to render a real and tangible service.

If the Institute will revert to the ideals of its founders, honoring those ideals in their performance, it will have found itself, and once it has found itself, we may be confident that it will become an active and important factor in the development of our mineral resources.

*The increase during the war period was at the rate of 61 members annually.

CHARTER OF THE CANADIAN MINING INSTITUTE

An Act to Incorporate the Canadian Mining Institute

[Adopted by Parliament of Canada in 1898]

Whereas the persons hereinafter named have, by their petition, represented that an association known as the Canadian Mining Institute has been founded by the said persons, and others, for the following purposes, namely:

First, to promote the arts and sciences connected with the economical production of valuable minerals and metals, by means of meetings for the reading and discussion of technical papers, and the subsequent distribution of such information as may be gained through the medium of publications. Second, the establishment of a central reference library and a headquarters for the purpose of this organization. Third, to take concerted action upon such matters as affect the mining and metallurgical industries of the Dominion of Canada. Fourth, to encourage and promote these industries by all lawful and honourable means. And whereas the said persons have prayed that it be enacted as hereinafter set forth, and it is expedient to grant the prayer of the said petition: Therefore Her Majesty, by and with the advice and consent of the Senate and House of Commons of Canada, enacts as follows:

1. John E. Hardman, George M. Dawson, William A. Carlyle, Charles Fergie, John Blue, B. T. A. Bell, A. W. Stevenson, James McArthur, Archibald Blue, William Hamilton Merritt, F. T. Snyder, Henry S. Poole, Wilbur L. Libbey, Rogert G. Leckie, Clarence H. Dimock, Geo. E. Drummond, Geo. R. Smith, J. Obalski, John J. Penhale, R. G. McConnell, Frank C. Loring, John B. Hobson, and William Blakemore, together with such persons as hereafter become members of the Institute are hereby incorporated under the name of "The Canadian Mining Institute," hereinafter called the "Institute", for the purposes set forth in the preamble.

2. The Institute may acquire and hold such lands and property as are necessary to carry out the objects and purposes for which incorporation is sought: provided the annual value of the real estate held at any one time for the actual use of the Institute shall not exceed five thousand dollars.

3. The Institute may make such by-laws, not contrary to law, as it deems expedient for the administration and government of the Institute.

4. The affairs and business of the Institute shall be managed by such officers and committees, and under such restrictions touching the duties and powers of such officers and committees as may be described by by-law.

5. The head office of the Institute shall be in the city of Montreal ,or in such other place as may, from time to time, be determined by a vote of two-thirds of the members of the Institute.

PROGRESS AT BLUE QUARTZ MINES

Recently there was reported from the Blue Quartz Mines on Painkiller Lake, six miles northeast of Matheson, Ontario, the discovery of an additional ore-shoot as the result of underground development. Samples of this ore are of unusual richness. It is not known publicly what are the milling grade or the probable dimensions of the new ore-body. A number of promising veins had been encountered previously, and in a hand-picked lot of rich ore approximating half a ton in weight, the Temiskaming Testing Laboratories at Cobalt determined a value of $246. per ton.

The development of this property under the present management has been pursued vigorously and honestly. Mr. H. C. Crow, president of the company, returned from England recently after arranging for the provision of the funds necessary to determine and to develop ore-shoots, and to build a mill when its construction is warranted.

Reports from Fort Norman, in the far north on the Mackenzie River, reveal that the early winter has not checked drilling for oil in that territory. The original well at Fort Norman of the Imperial Oil Company is still producing seventy barrels a day and this fluid is found of great value locally.

That the increasing demand in Eastern Canada for the product of Manitoba's granite producing industries will bring about rapid development of these industries, is assured. Both red and grey granite has been taken out during operation of the quarries within the last two years, and it is expected the industry will develop rapidly since a market has been found in the East.

Safe Explosives

THE EVOLUTION OF EXPLOSIVES PRACTICE IN THE COAL MINES OF CAPE BRETON

by JOHN MOFFATT

The use of explosives plays a large part in opening up coal mines and in the production of coal. Without them development would be slow and the work of breaking down coal very laborious and costly. There is abundant evidence of this in the cases of collieries which, owing to heavy gas outburst or explosions, have prohibited the use of explosives and yet continued mining. In the year 1891 an explosion occured in Springhill, causing the death of 126 persons. An investigation disclosed that the cause was due to a blown-out shot in a dry and dusty section of No. 1 mine. By common consent of both the employer and employees, explosives were abolished from Springhill collieries and up to the present time they have not been used, except in the new mines lately opened up. The great depth and overhead pressure of the older collieries now renders their use unnecessary. The work of mining, however, was at first very hard and although the ton rate was increased yet it scarcely compensated for the added labor in wedging down the coal. Many other collieries since then have had the same experience. Cassidy colliery, near Nanaimo, B. C., is one of the latest to which our attention has been drawn and the fact that a delegation of miners approached the Provincial Minister of Mines and protested against the new order prohibiting the use of explosives in the Cassidy colliery, and argued for "the judicious use of powder" shows the value placed upon its aid in mining coal.

The Use of Black Powder

Many of the smaller and a number of the larger explosions were long ago traced to the use, and sometimes the abuse, of black blasting powder. It was an everyday occurrence to see the working face at the time of blasting lit up by a sheet of flame, especially if holes were overloaded and the room was dusty. This was followed by thick clouds of black smoke, which added to the dense darkness of the mine and caused one to grope his way along. If ventilation was poor, this smoke filled the chambers all day long and men breathed it and became slowly poisoned by inhaling carbon monoxide and carbon dioxide gases. In the dry and dusty sections, it was not uncommon to see a heavy shot which had by its concussion thrown the dust into suspension, set fire to it and run along, burning for two or three hundred feet. The writer knew a happy little Englishman, who every day of his life sang just as blithely as the "Miller of the Dee", and while working in a dusty section told almost every evening of the fires occurring in his bord and pointed to his singed whiskers and hair as proof. But one day he, with many others, was missing and when found his body was burnt beyond all recognition. A blown out shot, a dusty section and an explosion told the whole story. But men were slow to learn, and even after it was proved beyond doubt that the use of black powder was dangerous and laws governing its use were enacted, these were not strictly enforced and infractions were frequent.

My Experience With Black Powder

Scientific investigation led to the discovery that in a badly ventilated bord the gases left by the firing of loose powder are inflammable and will, under certain conditions, explode. This knowledge had slowly filtered into enquiring minds. Mine officials, while not absolutely prohibiting the simultaneous firing of several shots in the same bord to guard against an explosive mixture, began to frown on the custom. The writer was then a shotfirer and a student of mining, and had been in the habit of firing the two side shots of a bord immediately after the middle shot was fired. Second reports began to be heard after the shots had gone off. These were common, but were attributed to the gases liberated from the coal when the shot was fired. Having read shortly before that about the inflammable nature of the gases left by the exploding of black powder, the dust created in the breaking down of the coal and the high ignition temperature at the time of explosion, and also about the high temperature of the gases remaining in a badly ventilated bord, I began to understand the danger of this practice and decided, except for experimental purposes, to discontinue it. One bord further in than the other along the airway gave very heavy second reports. Having satisfied myself that the theory of inflammable combustion from black blasting powder was correct, I decided never again to fire two shots at the same time in the same room. I had been in the habit however, of loading both holes at the same time and of leaving the needle in the second one until the first one was fired. One day two leading officials of the mine came in just as I was about to fire the first shot. As miners usually do on such occasions, I sat down and we had a friendly chat. Being in miners' "cutty sark", I was cold when they left to go out. Without thinking of what I was doing I drew the needle of the second shot and lit the two squibs. Suddenly it dawned on me what I had done. I knew what would happen and I ran to gain the shelter of the first crosscut and reached the next room, but the after report blew doors open away down on the level road and made such a loud report and such a shaking through that section that the officials came running back to see what had happened. To their enquiry I replied that it was only a second report and these men, though in official positions, were satisfied with my answer. Last some present official, seeing this, should have any perturbation of mind, let me assure him that both officials are out of the business long ago and one is beyond the "weeping", if not the "smiling". For me, after that, black powder had its dangers and when later on pellet powder began to be introduced, I welcomed it.

Pellet Powder

Here, however, began a new experience. Custom in the use of handling loose powder had led to carefulness, although now and then accidents occurred. But with the introduction of pellet powder a large number of miners were burnt by the careless handling of this explosive. It appeared so harmless and was found to be so handy that it could be slipped into the coat pocket or the shirt breast and be hidden there until a reckless smoker thrust his hot pipe inside and there [illegible] resentment and an accident.

These pellet powders had some of the characteristics of loose powder and flaming continued on blasting. Finally, by agreement between miners and employers, a test of the different kinds was made. It was found that all flamed more or less. The worst were eliminated

and the safest was selected to be used only until such time as permissible explosives could be introduced. The collieries had reached such depths and were now subject to such conditions as called for the best explosives. No one disputed this, and the "permissible" came in with the welcome of a friend.

Permissible Explosives

The mining law of Nova Scotia not only recognizes the worth but the dangers of permissible explosives, and has regulated their use as follows:

"No explosive other than a 'permitted explosive' shall be used for blowing coal in any mine unless permission to use some other explosive is given in writing by the Inspector and the Deputy Inspector of the district in which the mine is situated, and no explosive shall be used in any mine except in accordance with the following regulations:

"It shall not be stored in the mine, or within two hundred and fifty yards of the slope or shaft, or any place not approved of by the Inspector, provided that the storage of permitted explosives shall be allowed near the mouth of the shaft or slope of a mine in such quantity as may be required in the mine for one shift, in a building to be selected by the Manager of the mine and approved by the Deputy Inspector, and further provided that detonators shall not be stored in the same building.

2. "It shall not be taken into the mine except in a secure case or canister containing not more than six pounds.

3. "There shall not be at any time in any one working place more than one of such cases or canisters."

The conditions under which it shall be used and the supervision of its use are all carefully regulated, if not by law then by special rules drawn up and agreed to between the management and the miners of each colliery. These rules vary according to the conditions underground. If the mine is shallow and free from gas, loose powder may be used, but if it is deep and gaseous nothing but permissible explosives is used.

A permissible explosive is one that has passed certain tests and has been authorized by the Minister of Mines to be used in a gaseous or dusty mine. But it is not permissible unless used in the manner specified by the Department. Most permissible explosives have the general character of high explosives and all are entirely different from black blasting powder in composition and action. They give a shorter flame, explode more quickly and are much more powerful. The average miner is inclined to believe that flame is entirely absent when permissible explosives are used. This is a mistaken notion.

Three explosives in common use in the collieries of Nova Scotia are Monobel No. 1, Viking No. 1 and Polar Monobel No. 3, their composition being as follows:

	Monobel No. 1	Viking No. 1	Polar Monobel No. 3
Nitro Glycerine			
Poly-Glycerine	9.5 to 7.5%	11 to 9%	11 to 9%
Ammonium Nitrate	70 to 66	61 to 57	60 to 57
Wood Meal	9 to 7	10 to 8	10.5 to 8.5
Chloride of Sodium	16 to 14	21.5-18.5	20.5 to 18.5
Carbonate of Calcium			1.5 to .05
Carbonate of Magnesium		1.5 to .05	
Moisture	2 to —	2 to —	2 to —
Charge limit	10 ounces	26 ounces	34 ounces
Velocity of Detonation	8950 ft. per sec.	7718 ft. per sec.	per sec.
Pendulum Swing	2.81 inches	2.44 inches	2.47 inches
			6600 ft.

The Charge Limit means that only that weight of explosive can be used in any one shot hole at one time with safety. The Velocity of Detonation shows how quickly combustion takes place when the explosive is detonated, and the greater the velocity the more shattering will result. The Pendulum Swing is a measure of strength, therefore the greater the swing the stronger the explosive.

The composition of the permitted powders shows chloride of sodium, which is often spoken of as the cooling salt. When explosion takes place great heat is liberated and the chloride of sodium checks both heat and flame, as much heat is spent in reducing this salt to steam and the steam produced also checks the flame.

The compositon of black blasting powder is:—

Sodium nitrate	75%
Charcoal	15%
Sulphur	10%

Rapid action and rapid cooling are the principles on which the safety of permissible explosives are based. Practice has demonstrated the principles as sound, for mine fires rarely occur where these explosives are used.

Trained Shot Firers

Following close on the heels of the permissible explosive came the certificated shotfirer. This class does the same work as is now done by the shotfirers of the United States. Since then the Nova Scotia Government has seen fit to discard the name shotfirer and now all shotfiring is done by the examiner. In reality the shotfirer must be an examiner, for "no shot can be fired without first making examination of the place to be fired and the places contiguous thereto."

Just as discipline came with the introduction of the safety lamp, so the education of the miner began when permissible explosives were introduced. It was plainly seen that if all miners were permitted to charge their shots there would be much overloading, much smashing of coal, and increased danger. There was then much unskilled labor in the collieries, so a new system had to be devised which placed all shotfiring under the care of expert miners.

Systems of Shotfiring

There are two systems of shotfiring in the Cape Breton collieries, the mixed system, where shotfiring is carried on by day when men are in the mine, and the single system, where shooting is all done by night when all men are out of the mine. Each system has its advantages and drawbacks. When it was decided, in the interests of safety, to have all shotfiring done by night the miners entered a strong protest, pointing out the inconvenience and the loss of time it would cause to miners and the consequent loss of output to the mines. One mine, however, adopted the system of firing by night and it was found to be a great success. The one thing that it did determine was when coal is shot down by night and a report made of the number of places containing coal with the quantity in each place, the management knows just how many men are needed to fill the coal and how many cutters are required to mine it, and it became a rare thing at that colliery to see men coming out of the mine for want of something to do. It had the opposite effect from that expected and pointed out by the miners. There was no inconvenience, no loss of time and no reduction of output.

Another advantage it possesses is that the shotfirers and their helpers, who charge and fire the shots, can

begin to shoot in that part of their sections close to the return airway, which carries off the fumes and dust. This gives a purer atmosphers to work in and to the old miner turned shotfirer who long ago breathed powder smoke all day long, it is very much appreciated. This system has not, however, become general and in a colliery working two consecutive eight-hour shifts it is an impossible system.

The mixed system does not tend to a maximum of safety. It has, however, the advantage that under the supervision of expert men the miner does all the work of getting the shot ready and in this way a larger number of men are being gradually trained and educated to the proper use of explosives. The shotfirer does not load the coal and has no desire to break it up. Shots are fired one at a time when the miner wants them, and the risk from firing large quantities of explosives within a short tie is lessened. The mine atmosphere is never heated and overloaded with powder fumes and better examination can be made after the firing. As a system it is more flexible and readily lends itself to the new conditions that constantly arise in a coal mine.

Selecting Explosives

As coal differs in texture, some kinds being open and others being compact, experiments are necessary to find out the explosive best suited for blasting. A number of these were and are still being carried on in the Nova Scotia collieries. After examining the records, the explosive giving the best results was selected. Permissible explosives were in this way established and although the first explosive used was long ago discarded and many others tried since then, it has been found that the texture of Cape Breton coal is such that the same explosive gives good results over the entire field. Miners through practice become expert in the use of any explosive and no change should be made, unless it is necessary. Any change in explosive is immediately noticed by the miner, who having no knowledge of the strength and action of the new explosive, may make bad shots and much small coal. It is in the interest of the management in case of the necessity for a change to inform the miners and shotfirers, giving them all the data they have obtained from the manufacturers.

During the war the supply of British explosives was cut off and a new supply had to be found on this side. For a time there was much vexation of spirit and many bad and missed shots, but when the cause was explained it was agreed to carry on and do the best possible until practice had been made perfect.

Tamping Still Necessary

The stemming of holes charged with black powder had become a fine art in early days and few miners failed to do this. The hole was stemmed as hard as it could possibly be. If not, a blown out or windy shot, endangering the lives of all in the mine, might take place or else the coal would not be broken down as desired. A loosely tamped hole required a heavier charge of powder and when miners pay for explosives costly methods must be eliminated. But somehow when permissible explosives were introduced, it got into the mind of miners that, these being high explosives and of the nature of dynamite, tamping was not necessary. The more expert miners soon discovered the difference and tamping was carried on as usual. In place of the heavy copper headed tamping bar a light wooden rod is now used which serves the purposes well. Some miners thought that loose tamping close to the charge gave better results than firm tamping all the way through. But all soon discovered that solid tamping was necessary. For this purpose and to ensure safety, moist clay is sent into each mine and placed close to the working faces. Tamping with loose coal is strictly prohibited and all who attempt this dangerous practice are sent out of the mine. The charge of a shot which misses fire cannot under the law, be drawn. A new hole placed at a safe distance from the loaded one must be bored.

Electric Detonation In Use

The magneto battery and electric detonator are used in Cape Breton collieries. The detonators are in charge of the examiners and are carried into the mine by them. Electric cables are used to set off the shots. Only one shot is fired at a time in any one place. When the shotfiring system was first introduced and the electric battery came into use, several bad accidents occurred to miners, who, to help the shotfirer, stayed in the place and connected up the cable with the detonators. Failing to see the miner in the distance and thinking him gone out of the place by another way, the shot was fired and the miner either killed or badly injured. This is against the rules of the mine, and is heavily penalized.

Permissible explosives, because of their power and rapid action, make a larger percentage of coal of small sizes than black blasting powder. This has been the general experience in the coal mines of the American continent. Because of this the cost per ton of the output at the mine mouth is higher than if a slower and weaker explosive were used. To find some such explosive, experiments are being constantly carried on under the supervision of engineers of the mines in conjunction with the manufacturers. It is a big problem and presents many difficulties, but the engineers who have succeeded in producing an explosive that has greatly reduced the risk of mine fires and explosions will, no doubt, succeed in finding an explosive capable of giving as good or better results than black blasting powder.

Additional Precautions

Complaints are frequently made by miners of bad powder. This usually occurs in winter when the temperature is low. This has been remedied by the removal from the general magazine to a warmer building of a quantity sufficient for a shift. All electric blasting caps are tested before being given out. This is to prevent misshots, which are a loss to the miner and the mine's output. It sometimes happens, however, that the Inspectors from the works where the powder is made have to be called in and consulted before the real cause of complaint is removed. This only happen when the miner and his manager are unable to agree as to the seat of trouble. Special tests at the working face are then made and are carried on until satisfactory results are obtained.

Miners have been known to refuse to use a superior explosive because of some slight accident in its normal use. Forcite Gelatins, because of their slower action and lesser fumes, are preferable for underground rock work. They are less bulky and more plastic than nitroglycerine dynamites and can be got to the bottom of holes where the explosive does most good. Yet the [illegible] Wabana iron ore mines, because of prejudice, [illegible] persuaded to give up dynamite for Forcite. Flameless explosives are not, however, permitted [illegible]

The use of Canadian calcium carbide in India is increasing rapidly.

News and Comments

BY ALEXANDER GRAY

"Possibilities" of Shining Tree

In effect and to the purpose, Dr. Harvey W. Weed tells the owners of Shining Tree district properties to go to work; that "all that is needed" is "underground development" He confirms the judgment of Ontario's own geologists that the country has "possibilities" Guardedly optimistic, as scientists must be in the circumstances, he considers it "probable" that the right sort of development "will open up ore bodies of considerable extent and milling values." Incidentally he admonishes those most concerned that high-grade, "bonanza" ore in small quantities is of "minor importance at Shining Tree as it was at Porcupine." That exceptional condition need not "discourage deep work, because it is the universal experience that the medium and low-grade ore body makes the more reliable and longer lived mining camp."

Otherwise, the law of averages is paramount. Dr. Weed expresses confidence in the "attractive possibilities," which is all-sufficient provided those who claim to have "another Hollinger" and so tax the limit of credulity, get to work. Crescendo literature will not make mines. Shining Tree owners are aware of this. Shining Tree is eleven-year-old and the "possibilities," like the "Blue Bird," were there all the time. However, it is reassuring to have Dr Weed go on record that he is "quite favorably impressed." The Henderson "Holding"-Universal Tool Steel aggregation of golden areas should modulate its representations accordingy

Indian Mines, Portland Canal

Toronto and Montreal men of means with knowledge of the case are obtaining encouragement from their Indian Mines undertaking in the Portland Canal country. They have an arrangement by which they take stock as they go along, and ultimately, if development continues satisfactory, they will have control. A considerable amount of work has been done. Much of it, of an exploratory character has resulted in disclosing ore of profitable grade. While the section is belived to present several veins, the management under Mr. Hurner, with Mr. Clothier in supervision, wishes to confirm this. An upper tunnel was in 162 feet early in the current month, and Mr. Clothier reported the ore body had widened to 15 feet 6 inches, with ore on both sides of the drift. At the time of writing Mr. Clothier said the management was feeling for both walls. The average of the vein across the face was stated to be $17.50. In a few days it was hoped to reach the section vertically beneath a high-grade surface showing. In a raise Mr. Clothier said there is ore averaging $25 across 20 inches. The lower tunnel, 150 feet vertical fom the upper, is thought to be on another vein system, according to Mr. Clothier. There again, good values have been obtained. While the respective workings have yet to be lined up, those concerned in the ventnre are proceeding upon the assumption that the property is outgrowing its prospecting equipment.

London Quotations Wanted

Taking note of the editorial comment upon the desirability of London quotations for more Canadian mining shares, those of us who have trodden the speculative wine press in Throckmorton street and "between the chains" in in ye olden tyme in Johannesburg—who saw the bourse and boersen bubble and boil over—registered a smile. For several leap years a few of us fogies have cherished the hope that London would develop a more than casnal interest in Canadian precious metal mining. and take a larger share in standard issues.

London, though, has been a law unto itself. It has chosen to remain on the ragged edge of Canadian mining things. What it took of Cobalt, apart from the Townsite, was unproductive. Of course, it has the Aladdin, and the residuary rights in the Chambers-Ferland. The Keeley it retains, and has no reason to complain. At Porcupine it has the Davidson, and it has interests at Matachewan and in Shining Tree; but it turned down the McIntyre, forfeited its holdings of Hollinger (aside from what the Anglo-French people retain), and it is recent history that the Northern Ontario Exploration and Porcupine Development companies of Bewick-Moreing are now the Goldale, under Lewisohn auspices. One outstanding Group, perhaps the most important of all in South Africa, tentatively proposed to entertain part of what now is Hollonger Consolidated. The owners delicately intimated that their idea of the value of the ground did not coincide with the London-South African view.

London has a substantial holding in the V. N. T. At Kirkland Lake it has the Kirkland Lake Proprietary and blocks of Lake Shore. It has title to Gull Lake, and is looking for unearned increment. The Ankerite was conditionally recommended to a London group, and was not availed of. The same group had a piece of the Rea, and dropped it. Prof. Frecheville and Mr. Tyrrell have been on the spot. The latter never faltered in his faith in certain of the Porcupine properties, but the London interest in them is negligible.

We were told, a while back, that a London Securities concern had taken an option on "Hattie" shares. The Latilla group has been active at Cobalt and Kirkland Lake. Not all could be accomplished that this group aimed at. London prefers the "Bingo." At Elbow Lake the London Exploration Company took on an area. The short option and initial payments required resulted in abandonment of the enterprise.

This recital need not be laborious. Londoners of experience would rather "make their own script." They have been indiscreet, and occasionally incorrigible, declining to invest in established shares but accepting the problematical. Undoubtedly London quotations would attract attention. More important is the need of discriminating London capital and a clearer conception of the potentialities of Canada's precious metal areas.

Undoubtedly the basis upon which London capital was sought has precluded equitable arrangements. That, however, need not prevent more than spasmodic interest, where the situation is broadening and prospects more than ever attractive. Besides, the second-storey front is safer than something reached by the rear or by the alley.

Nipissing Directors Warn Shareholders

"Grafting" must be easy or else the grafters must be in desperate plight when brazen members of the profession make hurried appeals to holders of shares in reputable mining companies to sign their certificates in blank and send them along in order to obtain participation in other issues. Hollinger directors promptly notified their shareholders to be on their guard against separationist gangs. Nipissing directors also have found it necessary to circularize their shareholders. Evidently the business of robbing the too-confiding of what is worth having, and substituting what could not have merit, is being extended. Washington authorities are taking note of this. It used to be oil stock.

Now it is new-fangled mining schemes and radio propositions. It behoves both the wary and unwary to keep the padlock on their susceptibilities.

The Geological Mentor Ruminates

The Sage of the Slide was sententious, as becomes one eminent in his profession, when it was suggested that the porphyry has been mineralogically munificent. "Don't forget the Algoman Granite," he said. "You hear a lot about the porphyry, but the porphyry has to be considered in relation to the Algoman; and we have been slow in realizing that to the fullest extent. The Algoman is the source of the gold and the cause of the porphyry occurrences, which give us those contacts which are worth staking and exploiting. We have to be Calvinistic in these matters, accepting both Genesis and the Revelations. Wherever there is a strong Algoman development and the genetically related porphyry, I have maintained we are going to find minerals beyond the ken of Canadian men of wealth who appear to be oblivious of these features. Quebec?—of course it will have old fields—not one, but four or five, in my judgment from observation of the Algoman masses. Only one of the five may be of great importance, but it does not follow that more of them will not offer gold mines. Wherever there are contact conditions under the circumstances, I believe Canadians with working capital should devote some of it to the exploitation of the country's mineral wealth. The latest Quebec gold area has the geological essentials. Now we should leave nothing undone to explore the contacts. I don't mean to say that every porphyry outcrop is going to prove a profitable prospect. Isolated patches of porphyry are not what we want. Around the confines of the Algoman intrusions is where we are going to find gold fields, just as we have in western Ontario, Porcupine and elsewhere. Rouyn Township should provide mines. Boischatel also is good. In other sections I know the Algoman presents opportunities. Our important men of means ought to display their confidence in the country, which we are at least beginning to understand. Demonstration of our wealth must not be left to those least able to do all that is needed. In this way, by having large investors do the initial financing, we could avoid much of the mischief wrought by indiscriminate promotions."

Hitch In Asbestos Deal

The Johns Manville interests are to have their new large mill fully equipped according to the best practice in the no distant future. The site of their fabricating-on-the-spot plant is located, and its construction will go ahead in due course. But there is a rift in the lute as to the acquisition of certain other property. The information is that drilling has stopped, as well as other work. Montrealers, in stickling, are said to have injected flies into the ointment.

Strong Position Of Zinc

In contrast with the inadequate copper market, zinc producers find their metal in a very strong position. Were costs lower (but they cannot be) producers would be more willing to operate on a larger scale. They are awaiting a further advance in the market before they increase their output. By that time stocks on hand will be inconsiderable. The current market quotation is 7.35 cents a pound at East St. Louis, which is an advance of a quarter cent in the week ended the 11th. Shipment continue heavier than production. As there was only 18,043 tons on hand on November 1st, and the business doing is at the highest rate in two years, it is easy to see that the Consolidated Mining & Smelting Company, and others in the west, are experiencing prosperity. Had the Federal Zinc people been given a small measure of official support during the past two years, Gaspe might have been in the running now with bulk production.

BOOK REVIEW

ELEMENTARY GEOLOGY, with Special Reference to Canada A. P. Coleman and W. A. Parks — J. M. Dent & Sons, London and Toronto—363 pages, illustrated.

For the better part of a century the geological history of Canada has been the subject of study and of systematic record. A few students, professional geologists, in our country are familiar with this record, vast though its dimensions have now become. A larger number, mainly economic geologists and mining engineers, have studied all available data regarding special areas of industrial importance. There remains a very large number of Canadians who would like to know the gist of our country's geological history and its present geological appearance that have, heretofore, not found available a text suitable for their purpose. This want has now been supplied.

Professors Coleman and Parks of the University of Toronto are too well-known throughout Canada, and particularly in eastern Canada, to need any introduction in these pages. Their book is a welcome addition to our technical literature, and promises to become as well and favourably known as are the authors. It is written with admirable directness and simplicity, as befits the work of accomplished teachers, who have, withal, spent most of their days with Nature.

Wherever possible, the text treats of Canada. We have within our borders a sufficiently wide range of rocks to illustrate the geological scale of time almost in its entirity. In many cases it is, of course, expedient to treat the North American continent as a whole, and in this we find our Canadian authors in agreement with the principal findings of the best-informed geologists of the United States. There are few of the 197 illustrations that are not Canadian, and readers from coast to coast will find among them pictures of local interest. Dr. Coleman's own field researches have supplied a large fraction of them. A distinctive feature, and one that is relatively new, is the series of outline maps showing the distribution of the principal geological rock formations throughout Canada. This is accompanied by a second series showing the conformation of the land surface of North America during the successive eras when these rocks were laid down in the adjoining seas.

The book is in two sections, the first, on Physical Geology, describing the mineral constituents of the earth's crust; the way these mineral particles are joined to make rock masses or strata; the agencies that wear down the land surface distribute and again collect into rocks the particles, and the observable phenomena and unseen processes that are usually included under the term Structural Geology.

The second, and larger, section deals with Historical Geology. The making of the world, and then the successive stages of Canada's history from primordial times are presented by means of the evidence afforded today on the surface of our land. The [illegible] of plant and animal life of the successive eras and periods, which ordinarily monopolizes the space available, is here kept within reasonable bounds, more or less with its true relative importance in the story, though it still has a prominence that is hardly its due.

The writers have (contrary to the practice of numerous writers of geological texts recently) avoided

the mistake of giving undue prominence to those particular fields of research in which they have specialized. They have also moderated in large degree the use of multifarious and unnecessary geological terms that mass so much of the writings of geologists on this continent. We would suggest, for future editions, a still simpler technical terminology. On several pages interested readers will find shrewd controversial thrusts on disputed points—but Dr. Coleman has pressed only with a very admirable moderation this advantage, and prerogative, of the writer of books.

The book is dedicated by the authors to the use of the general reader and persons engaged in the mining industry in Canada. We would add students of elementary geology in our colleges, and can recommend it most heartily to them all.

LETTERS FROM READERS

Canadian Iron Ores

To the Editor, Canadian Mining Journal.
Sir,

Kindly permit an old contributor to the Journal, to dispel a mist that has darkened the vision of old and young, of interested and less interested persons in the eastern part of our country, in regard to the economical value of our iron ores for so long. . . .

It is known that we have in our two western districts of Ontario alone over 300 miles of continuous deposits, principally magnetite, and about one-quarter of that hematite. These deposits are so extensive and varied that from them we could supply the whole world for centuries. This is no exaggeration for we can prove that diamond drill holes put down to a depth of 1000 feet did not reach the bottom. And if we use the figure furnished by our stratigraphical geology, we may claim for them a depth of over 10,000 feet, while the width is in most parts of the range 1400 feet.

The dimensions quoted are those of a range which have been thoroughly propected and is accurately known the length of which has been ascertained to be over 100 miles.

Using the above figures for arriving at the cubic ore contents of this one range alone, we are confronted with a tonnage which would stagger the imagination. Now we have three iron ranges, the middle range is the one just mentioned, while the northern is the most extensive.

Most of our ores are magnetites of two distinct classes, one jasper banded and the other an intimate mixture of gangue and iron oxide particles. Now since the ore is magnetite and easily attracted by the magnet, can anybody claim that it needs serious study and experimentation to determine whether it is of use for technical requirements? It will take no more time than it will take to make a general analysis of the crude ore and one of the concentrates. The preliminary concentration test is done with a simple instrument, which I constructed over 20 years ago, and is extensively used now in the metallurgical department of the University of Minnesota. . . .

I have had repeatedly the visits of the engineer of the Babbitt concentrating plant, and guided him over a part of our Mattawin Range, from where he took large samples, and returned home more than delighted, yes, astounded at what he had seen. Please ask him, Mr. Editor, if there is indeed a problem to solve, as your recent article in the Journal would indicate. In conclusion let me make you and your readers aware that the Babbitt concentrating plant in Northern Minesota, which handles daily 4000 tons of run-of-mine ore, is situated at the south end of our Mattawin Iron Range, and treats there a low-grade magnetite from 26 to 30% iron content without the slightest difficulty.

The average iron content of *our* ore is 37.72%. Do I need to say anything about the Swedish and Norwegian ores, which are of the same quality as ours, for which they have even ventured 230 miles inside the Arctic Circle, where one company alone, the Sydveranger, is treating 1,800,000 tons yearly? And is it necessary to mention the many Swedish plants that have operated over twenty years now, every ton of whose product is eagerly taken by English and German Iron Works? I am sure you have also heard of the Pennsylvania and New York concentrating works. Should all these plants not offer sufficient material for a determination what to do with our own ores?

Don't let us give our Canadian engineers such a degrading "testamonium paupertatis" under the guise of lack of experience, not to possess the same intelligence and ingenuity as others to determine what can be done with Canadian natural resources.

All that the uninitiated in this branch of industry have to do is, to go and study what other people are doing. There are absolutely no puzzles to solve. If you have sufficient ore of your own, examine it closely, take it with you in your laboratory, test it, see whether your magnetic apparatus will separate the iron from the rock particles, and in what fineness; don't disintegrate it more than it is necessary; then make your concentrating test, and analyse the products; lastly, find out what is the most convenient way to agglomerate the concentrate; of the several methods in vogue, select the best adapted for your conditions; the rest is a commercial proposition.

Port Arthur, Ont. F. Hille

TALC AND SOAPSTONE IN CANADA

A report just published by the Mines Branch, Department of Mines, under the above title, deals with the talc and soapstone resources of Canada. The author is High S. Spence, and report comprises 80 pages of text, 17 illustrations and a map showing the distribution of the known talc and soapstone occurrences in the Eastern Townships of Quebec.

The report contains four chapters: Chapter 1 includes tables of analyses of tales and soapstones, notes on the distribution of the Canadian deposits, and a statistical section. Chapter 2 is devoted to detailed descriptions of Canadian talc and soapstone mines and occurrences; while Chapter 3 deals with the uses, mining and preparation for the market of talc and soapstone. Chapter 4 contains brief notes on talc in foreign countries. A bibliography of the more important literature dealing with talc and soapstone is appended.

From this report, it appears that while talc is known to occur in Nova Scotia, Quebec, British Columbia and Ontario, the last named province is the only one that has figured at all prominently as a producer.

The Nova Scotia occurrences are small and are not regarded as of economic importance. Quebec undoubt-

edly possesses important talc deposits, most of them yielding an off-colour grade of ground talc, which, however, has good slip and should be of value for the paper, roofing and foundry trades. A similar grade of talc is produced at several localities in British Columbia; and there is, also, in this province a deposit of cream coloured steatite, or massive talc, that shows some promise and that may with the improved transportation facilities afforded by the Castle-Windermere highway, prove capable of development.

The principal talc mines of the Dominion lie in the vicinity of Madoc, north of Belleville, in Hastings county, Ontario. The Gillespie mill at Madoc station has been in operation for the past sixteen years, and produces a superfine, white talc that is much in demand by the talcum powder, textile, paper, soap and rubber trades. Two other mills in the same district have been in intermittent operation for the past ten years.

According to the statistics of production given on page 13, the production of talc in Canada in 1920 amounted to 21,000 tons, valued at $167,000. Virtually the whole of this quantity was derived from the Madoc area, Ontario.

LARGE DEPOSITS OF RADIUM ORE DISCOVERED IN AFRICA

Lower Prices due to Discovery of Deposits

The national observance of "Cancer Week," when public-spirited men, most of them physicians, have shown anew the tragic seriousness of cancer, has again turned attention to radium as one of the principal agencies for coping with that appalling scourge. Radium is not a specific for cancer, for which there is no specific, but it has repeatedly proved to be of very great efficacy in the treatment not only of cancer but of some other diseases.

Almost simultaneously with Cancer Week, according to the United States Geological Survey, Department of the Interior, there has been a great drop in the price of radium; instead of the former price, $120,000 per gram (about 15.4 grains) of elemental radium, the price now advertised is $70,000 per gram.

A considerable reduction in price preceded this drop, because several manufacturers had on hand large stocks of radium, which, owing to the present financial conditions, were not sold readily. The recent great drop, however, was not due to this cause—it was due to the discovery in Katanga, in Belgian Kongo, of large deposits of very rich, easily worked radium ores and to the erection of a plant at Oolen, Belgium, about 40 miles from Antwerp, for producing radium from those ores.

Location of The Deposits

These deposits are at Luiwishi and Kasolo, near Elizabethville, in the extreme southern part of Belgian Kongo, and consist of veins on the property of the Union Miniere du Haut-Katanga, a British-Belgium company operating huge copper-bearing properties in Katanga. The veins carry pitchblende, which is in large part altered to gummite, uranophane, and other uranium minerals. A subsidiary company has been formed to extract the radium, and a considerable quantity of ore carrying many times as much radium as the carnotite ores that have heretofore governed the world's markets has been shipped to Belgium. No data are at hand, however, to show that in the aggregate the newly found deposits will eventually yield as much radium as the deposits in the plateau region of the United States, though a considerable quantity can be produced from the Katanga deposits at a much lower cost, and it is that cost that is ruling the radium market to-day.

Recognizing the value of cooperation, American companies, closing down their own mines, have undertaken to market the African product, and radium is therefore now offered at a price lower than any that has prevailed since it became an object of commerce, and an opportunity is thus given to branches of government, hospitals, doctors, and philanthropist to obtain the precious material at a minimum expenditure, for it seems probable that the price will go no lower. Eventually the principal source of radium will again be the carnotite deposits of the West, and when that time comes, if not before, the price will again rise.

The State of New York and the city of Philadelphia have each bought 2 grams of radium for the use of their cititzens, and the province of Quebec has bought 1 gram. It is hoped that other municipalities, States, or countries will buy radium at the present advantageous rates, particularly as the work done during Cancer Week is likely to occasion a great call on institutions for the treatment of cancer in its early stages, when it is most amenable to treatment by radium. Here is a remarkable opportunity for wealthy men to do something to help sufferers from cancer and some other malignent diseases that may be cured by the use of radium.

CANADIAN CHEMICAL PRODUCTION WELL MAINTAINED

The gross value of chemicals and allied products manufactured in Canada in 1920 was approximately $122,000,000 according to a report published last week from the Dominion Bureau of Statistics at Ottawa.

The report states that the actual capital invested in the 456 plants operating in this group of industries in 1920 was $120,000,000. Pigments, paints and varnishes made in 48 plants were valued at $27,000,000 and with this output was first in the field. The report covers ten principal industries producing respectively, coal tar and its products; acids, alkalies, salts and compressed gases; explosives, ammunition, fireworks and matches; fertilizers; medicinal and pharmaceutical preparations, paints, pigments and varnishes; soap, perfumery, cosmetics and toilet preparations; inks, dyes and colours, wood distillates and extracts; miscellaneous chemical industries.

The imports of chemicals and allied products into Canada have gradually increased from $3,169,000 in 1895 to $24,000,000 in the twelve months ending March, 1922. The exports of Canadian products of the same class has risen from $760,000 in 1892 to $9,000,000 in the twelve months ending March of the present year. During the war the great production of explosives in Canada and the shipment of this commodity to the war zone raised the Canadian exports of chemical products to a ground total of $57,000,000 in the twelve months ending March, 1919. The present export figures show that much of the advantage gained in the war time development has been retained and the fact that the statistics for the calendar year 1921 showed [illegible] plants were in operation as compared with [illegible] of the preceding year is further evidence that the chemical industries of Canada are more than holding their own.

As the principal raw materials for this industry are mineral products, the advancement of our chemical industry is of prime importance to the mining industry.

Geology of Mackenzie River Basin

FIVE REPORTS BY MEMBERS OF THE GEOLOGICAL SURVEY, OTTAWA

Summary Report, 1921, *Part B*, which is now available from the Geological Survey, Ottawa, contains five short reports on the Mackenzie River area, and a progress report on a coal area west of Calgary. The Mackenzie River reports are printed together as a matter of convenience.

Hay and Buffalo Rivers, Great Slave Lake, and Adjacent Country

This report by S. E. Cameron, based on field work, done in 1916 and 1917, describes the geology of the shores of Great Slave Lake and some of its tributary rivers. The lake, larger in area than Lake Ontario, has numerous deep bays and many islands. Round the northeastern part the rocks are exclusively pre-Cambrian, mainly granite, and granite gnessis, with minor amounts of greenstone, quartzite, conglomerate and limestone, all metamorphosed. Near the contacts with the granite these latter rocks were observed to have stains of copper and iron, but no evidence of deposits larger than stringers.

The Palaeozoic rocks to the southwest hold out more promise of economic value. Ten miles inland from Pine Point on the south shore are the lead-zinc deposits described in the *Canadian Mining Journal* on June 9th., last by Mr. C. B. Dawson, who opened them up in 1920 and 1921 and disclosed at least a million tons of ore.

The numerous superficial occurrences of oil on or near the shores of Great Slave Lake and the encouraging, though unsuccessful results of drilling, together with a favorable conjunction of porous and impervious rock strata, encourage the belief that suitable "structures" and eventually a "pool" will be found within this area.

Gypsum is abundant in several localities, notably on Peace river near its discharge into the Mackenzie, where there is evidence of many millions of tons, obtainable simply by stripping and quarrying.

Beds of salt of good commercial grade have been disclosed at McMurray at a depth of from 600 to 700 feet in a drill-hole put down by the Alberta government during 1920.

A general map of the Mackenzie river area accompanies this report.

Mackenzie River District Between Great Slave Lake And Simpson

In the spring of 1921 three geological parties descended the Mackenzie river together. E. J. Whittaker worked over the ground indicated above, while the others went further down stream. The difficulty of mapping this area is well illustrated on the maps, which shows level, boggy country with only occasional rock outcrops. The rocks are Devonian and Cretaceous in age, little "structure" was observed, and the formations are too low in the geological scale to be favorable to the occurrence of commercial quantities of oil.

Exploration East of Mackenzie River between Simpson and Wrigley

M. Y. Wiliams found here a more varied succession of strata and evidence of geological disturbances. Rocks from late Cambrian to Upper Devanian were determined. The hilly parts of the area have been too much disturbed to allow accumulation of oil, and in the level country, where there might be suitable "structures," there is insufficient outcrop to determine them.

North Nahanni and Root Rivers Area and Cariboo Island Mackenzie River District

G. S. Hume shares a map-sheet with Dr. Williams, his area of exploration lying westward across the Mackenzie. The rocks found are classed as Upper Devonian in age, though part of them may belong to the Middle Devonian. Part of the area has been too much disturbed by folding and faulting to promise oil. The plain, again, may contain "structures" beneath its surface with chances of oil, but the fewness of rock outcrops preclude any conclusion on this point.

A visit was paid to Cariboo Island in Great Slave Lake, where gold had been reported to occur in quartz veins. The rocks are green schist and pink arkose. No gold was found in the pits examined. The owners of the claims, held by the Aurous Gold Mining Company, were encountered later and explained that the gold-bearing veins had not been examined.

Geological Structure of the Mackenzie River Region

This report is a general study of the oil-bearing rocks east of the Rockies from the international boundary northward. With the aid of sketch maps D. B. Dowling outlines the geological history of the area, explaining the earth movements that have caused the area to be alternately sea and land, the deposition of the rocks of successive ages and the subsequent minor movements and denudation that have affected the possible commercial occurrence of oil. This discussion is based on all the known facts and correlates the numerous reports on the areas included. As Dr. Dowling is a master of his subject, this summary should be valuable as a "jumping-off place" for those that wish to study the area.

Kananahis Lakes-Palliser River Map Area

J. R. Marshall reports here his progress in mapping the coal-bearing rocks of this area, 40 miles southwest of Calgary, and the examination of the coal seams exposed. The coal is of the high carbon bituminous variety characteristic of the eastern slope of the Rocky mountains in southern Alberta. There are numerous thick seams already located and partially explored, and it is probable that more and even better coal will be discovered as prospecting proceeds. The only present means of transportation is by wagon. Railway connection to the Calgary-McLeod Line of the Canadian Pacific railway could be provided with little difficulty.

An air compressor (class ER-1) specially suited to small mines is described in Bulletin K-311, just issued by the Canadian Ingersoll-Rand Company. These new machines are produced in their entirety at the Sherbrooke plant and embody all the latest developments in compressor engineering. These include "Ingersoll-Rand" plate inlet and discharge valves; enclosed construction with automatic combined flood and splash lubrication at all speeds; forged steel connecting rod and crankshaft; removable die-cast bearing sheels, etc. The plate valve adopted for these machines is a modified form of the valve used for several years on the largest compressors, which was largely instrumental in making the direct-connected electric motor-driven compressor a commercial success. An outstanding advantage over all types of valve is that it requires no lubrication or mechanical valve gear and is supported throughout its entire operation in perfect alignment without any form of wearing guide. Regulation of the class ER-1 compressor is accomplished either by an automatic inlet unloader or by a "free air unloader" operating directly on the inlet valves. Bulletin K-311 presents an interesting comparison of the various types of compressor and contains other information of value to compressor users.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

MOND NICKEL OPERATIONS.—For the first time in four years the Mond Nickel Company is now shipping its entire production of matte to the refinery in Wales. Shipments are running at the rate of 5000 to 6000 tons a month. It is expected that by December the refinery will be operating at pre-war capacity, the demand for the metal having become substantially greater.

PANCAKE LAKE.—It is stated that the Crown Reserve is considering an increase in its capital. Recent developments at the Pancake Lake property have been very encouraging and an increase in capital would provide funds to carry on further work. At the 300-foot level the main vein showed a width of 22 feet, of which the first 12 feet assayed $10.00.

CANE SILVER.—Preparations are being made to sink a 100-foot shaft on the Cane property in the Elk Lake district. The property has some promising silver showings, but so far the work done failed to disclose a commercial ore body.

BAILLY ASSIGNS.—The Bailey Silver Mines, Cobalt, has assigned to the Toronto General Trusts Corporation. The company has a bond issue of $150,000 and recently sold its mill to the O'Brien for $75,000, leaving $75,000 of bonds outstanding.

NIPISSING.—During October the Nipissing mined ore of an estimated net value of $151,665 and shipped bullion and residues of an estimated net value of $228,579. The low-grade mill treated 5077 tons and the high-grade plant, 151 tons, while the refinery shipped 201,690 fine ounces of bullion. Shaft number 128 was closed down and the equipment moved to number 26 shaft, which is being reopened. Number 26 vein 5 was worked 11 years ago and produced 1,000,000 ounces of silver. It is expected to produce substantial quantities of mill ore, and in addition this shaft will be used to explore the diabase-Keewatin contact.

COBALT SHIPMENTS.—The only shipper from Cobalt for the week ending Nov. 10th was the Mining Corporation, which sent out five cars of residues containing 192,000 pounds.

KIRKLAND.—It is understood that the Tack Hughes has cut a new vein by a crosscut north from the 700-foot level. The new electrically driven plant of the Harvey Kirkland has arrived and will be installed immediately. Power will be obtained from the Montreal-Ontario transmission line. The Kirkland Board of Trade, despairing of the government doing anything toward the extension of the Kirkland road to the Argonaut mine and the Lightning River district, have decided to raise the money and do the work themselves. The need of a road to Lightning River was urged upon the Government almost a year ago but nothing appears to have been done. The building up of Northern Ontario must for a long time yet depend upon the development of the mining industry and it is the manifest duty of the government to provide suitable means of transportation to new and promising mining camps. Whether or not Kirkland is the logical starting place for a road to Lightning River, that district warrants a road and its building should not be left to private individuals.

DOME.—The Dome has completed the installation of a large crusher on the 12th, or 1450-foot level, which will facilitate work below the 8th level where the other crusher is installed. In opening up stopes below the 8th level difficulty has been experienced in handling large pieces of ore. Development on the 12th and 13th levels is now well under way. Ore bodies showing on the upper levels have recently been cut on the 10th and 11th levels where they show substantial widths of good ore. The Dome continues to maintain an output of about $400,000 a month and is the highest grade mine in Porcupine.

MCINTYRE.—The McIntyre expects its main shaft to reach a depth of 2375 feet by the end of the year. This is the deepest shaft in Northern Ontario.

$8,000,000 DIVIDEND FOR 1922.—Dividends from Northern Ontario mines for the year 1922 will be approximately $8,000,000. Of this amount $1,730,000 will be contributed from Cobalt, $492,500 from Kirkland Lake and $5,585,710 from Porcupine. Up to the end of the present year the gold and silver mines of Northern Ontario will have paid to shareholders a total of over $123,000,000, while if the dividend from the nickel-copper companies be included, the total amounts to $206,000,000. Dividend from Cobalt are $90,000 in excess of 1921 while Kirkland shows an increase of $370,000 and Porcupine $1,360,000.

ROUYN DISCOVERIES.—The recent discoveries in Rouyn township in northeastern Quebec have aroused a good deal of interest and already thousands of acres have been staked and several properties have changed hands. The Quebec Government recently changed several of the provisions of the Mining Act, the one change in particular which is of most interest to Ontario operators and prospectors being the abolition of the clause that permitted claims to be filed on in the land office without being staked on the ground. This change in the Mines Act and the discovery in Rouyn township will greatly stimulate prospecting in Quebec and will no doubt lead to other discoveries.

BOOTS STOCK ISSUES.—It is understood that the provincial Government will endeavour to have the Ontario Companies Act serve as a Blue Sky law in an effort to suppress a good deal of the [illegible] is now going on. An action was recently brought against Jackson Laing and Company for advertising shares of a mining company without having a prospectus [illegible] attempt is to be made to include under the term prospectus all literature and advertisements used to promote the sale of shares. If the courts uphold this view, all such literature and advertisements must be signed by all the directors and filed with the Provincial Secretary.

The power situation in Northern Ontario has become more acute again. The rubber on the Hollinger company and the Ontario government seems to be [illegible] that would allow of new developments on the Abitibi River is regrettable.

BRITISH COLUMBIA

Portland Canal Prospects.—A working bond on the Virginia group of five mineral claims, and also on the Torris group of two claims, has been taken by A. G. Larsen, of Spokane Wn. These properties are situated in the Salmon River section of the Portland Canal District northwest of the town of Stewart, on the Alaska side of the boundary. They lie astride the waggon road in the Salmon River canyon, about 12 miles from tidewater. Considerable work has been done by William Bunting, who put through the deal, showing up three strong leads, two below the road and one above it. A good grade of milling are has been exposed by a short tunnel. The bond covers a period of three years at a price of $75,000, with a 5 per cent, cash payment.

Railway for Portland Canal District.—G. A. Carlson, of the firm of Siems & Carlson, Spokane Wn., visited Stewart recently with Charles F. Caldwell. Mr. Carlson's business was to look into the possibilities in connection with the suggested construction of a railway up the Salmon River valley from tidewater as far as the international boundary. Mr. Caldwell holds a charter for a road over this route. It is stated that, with six promising mining properties rapidly developing on the Alaska side and more than that number in British Columbia territory there is sufficient tonnage in sight to warrant the expenditure that the road's construction would mean. Mr. Caldwell is quoted as saying that the building of the road is almost a certainty.

A Bear River Prospect.—A contract has been let by Fitzgerald Brothers for the driving of 150 feet of tunnel on the Independence Group, Bear River, Portland Canal district. This will give approximatley 125 feet of depth on the ore when completed. A crosscut in the face of the tunnel has proved the lead to be 15 feet wide, containing a good grade of milling ore.

Change in Mining Laws Advocated.—T. W. Bingay, of the Consolidated Mining & Smelting Company, Trail, and R. Randolph Bruce, of the Paradise Mine, Windermere, were in Victoria recently interviewing the Minister of Mines with reference to present methods of assessing mining properties for taxation. It is understood that, on behalf of the mine operators, they advocate some important changes in the provincial law, claiming that greater allowance should be made for mine depreciation.

Farmers Complain.—Mr. Bingay is believed to have made representations, as well, in regard to the petition of farmers living near the Trail smelter for compensation for loss sustained through damage said to have been caused by the fumes from the plant of the Consolidated Mining & Smelting Co. A delegation of farmers waited on the Government recently to discuss this question. A quantity of foliage, blackened and dwarfed, was exhibited as evidence of the devasting influence of the acrid smoke emanating from the smelter. Mr. Bingay denied that the fumes complained of were as bad as represented, asserted that the picture of destroyed crops was overdrawn, and declared that it was possible to pick up blackened and shriveled foliage almost anywhere. He displayed some leaves found on the grounds of the Empress Hotel, Victoria, which locality nobody could say was subjected to the chemical blasts of a smelter or any other industrial plant.

Prospectors Meet.—The Vancouver Island Prospectors' Association wants prospectors included among the classes of workmen entitled to the benefits of the Workmen's Compensation Act. The Provincial Government will be asked to consider making the amendment necessary to broaden the Act in accordance with the Association's wishes. At a recent meeting Thos. Golby gave a talk on the cinnabar deposits of Telingua, Texas, and W. Conway told of the Cedar Creek placer discoveries, Cariboo. He said that a real strike had been made with rich pay dirt. Considerable development had been done on three claims, Platt's, Steven's and Sheridan's. There was an instance of 176 ounces of gold being recovered in one day by two rockers operated by six men.

Kimberley Mines Active.—Accounts have been received of striking mining activity at the Sullivan Mine and at Kimberley in the East Kootenay district. The present output of the Sullivan is 1100 tons a day. The concentrating mill at Kimberley is being constructed as rapidly as the men can put together the material and the machinery. The capacity of this installation will be 1500 tons a day. While there still is little mining in progress at Rossland, at most other centres in the Kootenays there is an improvement. Estimates of the production of silver, lead and zinc for this part of the Province should show a substantial increase over last year, although no figures are available as yet upon which it would be safe to base a definite prophecy. Certainly the tonnage of ore received at the Trail Smelter is much greater and, while at present the silver market appears to be sluggish, the actual production of this and the other metals mentioned has been climbing.

Trail Ore Receipts.—Ore receipts at the Trail Smelter, Consolidated Mining & Smelting Co., for the week ending November 7 totalled 8,044 tons. Of this 7615 tons were from the mines of the Company. The remainder was made up, for the most part, as follows: Alamo, Alamo, 53 tons; Black Rock, Northport, 28; Knob Hill, Republic, 51; Paradise, Lake Windermere, 23; Quilp, Republic, 156; Silversmith, Sandon, 62; Standard, Silverton, 44; Telkwa, Telkwa, 2; and Whitewater, Retallack, 27.

Kootenay Claims Sold.—Purchase of the Wellington group of six crown granted mineral claims, adjoining the Whitewater Mine, was unanimously approved and authorized at a stockholders' meeting of the Slocan Consolidated Silver Mines Ltd. held at the town of Kaslo last week. This action was the culmination of negotiations extending over more than three years.

Address on Prospecting.—"The Mining Industry of British Columbia" was the subject of an address by Dr. S. J. Schofield, delivered recently before the Canadian Institute of Mining & Metallurgy, Vancouver B. C. He divided mining activity into five branches, viz., prospecting, development, production, smelting, refining and marketing.

Prospecting, he said, depended upon topography and the presence of glacial drift. In British Columbia the topography was rugged, the vegetation and timber almost impenetrable, and glacial drift covered the whole mining area. These factors, together with a winter lasting in some sections from six to eight months, made development as well as discovery very slow. He contrasted these conditions with those obtaining across the line, where the climate afforded twelve months of the year for work, and where there was little vegetation to overcome.

In considering the second question, development, the lecturer found that because the ground-water level of British Columbia was practically at the surface, most of the ore bodies were among the primary sulphides, while in the desert countries of the south the extremely low ground water level with its consequent seepage had produced oxides which responded to cheaper treatment

than the British Columbia product. This was the second handicap in an industry where capitalists looked for immediate results.

On the point of production, he was of the opinion that when this was once started on a large low-grade property, the industry had a long life before it and was a steady source of profit to a country where 50 per cent. of the freight carried by the railways came from the mining industry.

He deplored the loss accruing to the industry from the lack of smelting and manufacturing facilities. Trail and Anyox handled a tremendous output, but they were not enough. Raw products were shipped across the line for manufacture, and were shipped back with a duty on them. Manufacture represented the large end of the metal industry, and it was all being done outside the country.

Because most of the ore is of a low grade, mining here must be pursued very economically, and with all the aid that scientific enquiry into deposits and methods of working could give. No money must be wasted on the "hit or miss" methods of mining that had obtained in the past, if it was to compete successfully with the mining industry as carried on in the Western States.

In conclusion, he appealed to the youth of the province to take up the outdoor work in the hills for the development of mining on scientific principal rather than to devote all their energies to sedentary professions, where by they might be surrounded by the conveniences of city life.

Oriental Miners.—A return submitted by Hon. Wm. Sloan, Minister of Mines, to the British Columbia Legislature recently, showed that certificates of competency as coal miners are held by 428 Orientals, 253 of these being Chinese and 175 Japanese. They are entitled to work underground in the coal mines of the Province. The majority of the certificates were issued between the years 1902 and 1915, only nine having been granted Japanese from the year 1917 to date.

"Bump" at Coal Creek.—A severe "bump" occurred in No. 1 East Main, Coal Creek, Crow's Nest Pass Coal Company, on November 13th last. Although haulage and travelling ways of the main counter tunnel were shattered, no one was seriously hurt and only one man was injured. All men in the mine were withdrawn immediately and that section of the workings has been closed down temporarily. The movement appears to have been generally felt in the town of Fernie, a few miles distant.

Tour of Investigation.—Dr. Charles Camsell, Deputy Minister of Mines, Ottawa, and Mr. B. F. Haanel, also of the Federal Department of Mines, have been making a tour of Canada investigating the coal situation. The coal problem of Canada, it is thought, is mainly confined to the Province of Ontario. The Maritime Provinces and Quebec will be supplied by the Nova Scotia Mines, there being direct water communication from the mines to Montreal, and the westerly limits of the Province. Alberta mines are adequate to meet the demands of the Canadian prairies, while Vancouver Island mines can be depended upon to supply British Columbia. It may be added that the mines of the Nicola-Princeton Field and of the Crow's Nest Pass also afford a plentiful source of fuel for their section of the Canadian West.

Coal Output for October.—The coal production of British Columbia for the month of October was some 13,000 tons below that of the previous month. The mines of the Crow's Nest Pass, including the Corbin Coal & Coke Co., fell off in their output about 10,000 tons, no doubt because of the increase in the United States tariff, which practically closes the market south of the line. In the Nicola-Princeton Field most of the collieries show a slight decline. On Vancouver Island the Canadian Western Fuel Corporation is up approximately 3,000 tons, while the Comox Mines of the Canadian Collieries (D.) Ltd. are below and the southern collieries of the same Company a few tons in excess of the September production. The Granby Company's collieries at Cassidy have increased their output by about 4,000 tons. These fluctuations are due, no doubt, to the gathering strength of the domestic demand as winter advances and the weakness of the bunkering trade.

NOVA SCOTIA

Appointment Delayed.—No appointment has been made to fill the position of General Manager of the British Empire Steel Corporation at Sydney and, according to the statement of Vice-President D. H. McDougall, none is likely to be made just now. For a long time it has been openly advocated in the Nova Scotia press that the President of the Steel Corporation should reside in Sydney and that the interests of the Corporation would be advanced if this were done.

Mr. McDougall for Sydney.—Vice-President, D. H. McDougall, it is understood, is about to make his home in Sydney for some time. This will meet the wishes of the public who, knowing Mr. McDougall, are pleased that he is coming back. He is quite capable of representing the President in his absence. His knowledge of steel and coal affairs makes him invaluable and gives business and industry a feeling of confidence while he is near. Labor, too, has lately come to change its views of Mr. McDougall; indeed to those who observe closely it is believed that Nova Scotia miners never wholly lost confidence in him, although at times he was soundly berated. Like the business men and steel workers of Sydney, the miners became a little "peeved" over the prolonged absence of the man who thoroughly understood their difficulties, and who cared to listen patiently to their grievances. Mr. McDougall has given out the statement that the ranking officials will carry on both in Sydney and at Glace Bay.

Larger Stock Piles.—The large trestles of the coal floors at No. 2 Colliery, Glace Bay, have been extended to admit of a stock pile of 500,000 tons of coal this winter. If the weather is favorable for shipping, it will not be necessary to bank this amount, but the Company has sold a large quantity of coal and anticipate a good trade in the Montreal territory in the coming year, and are busy making preparations to meet it. Much of the coal shipped this winter may reach its destination by way of Portland. This may bring about busy times at the port of Louisburg, which for a number of years has been very dull. Probably no other industrial centre in northern climes can boast an open harbour all the year round when, at the other terminus of a railway eighty-nine miles long, the harbour is frozen up for three months each year. Sydney Harbour has a [illegible] and Louisburg a southern, entrance and that makes the difference.

Local Labor Conference.—On a recent occasion, several ministers of Sydney Presbytery met in one of the Glace Bay churches with representatives of the Labor Party and discussed [illegible] in a friendly way presented their complaints. A representation of J. B. McLachlan [illegible]

viz. "The early Christians were imprisoned and stoned to death, and present-day labor leaders receive the same treatment". He neglected to state that few of them meekly submit and none of them show those virtues in adversity for which the early Christians were noted. After last winter's exhibition by J. B. McLachlan, who shouted ferociously for all Canada to hear, who could think of him being "meek and lowly of heart"?

No Union for Steel Workers.—Determined attempts made to organize all the steel workers of Sydney into one union have failed. Superintendent Bischoff carried out the scheme of meeting representatives of workmen from the different departments. This method of settling labor complaints has been most successful in other steel plants. It excels the union method in that all departments may have representatives when grievances are to be discussed. It has all the freedom necessary to good relations and has for its objects the moral and material welfare of the worker and the progress of the industry. Sydney Steel Plant needs all the help it can get through co-operation between the workmen and their superintendents. Nothing short of this will enable it to recover lost ground.

Fighting Fire at Inverness.—The rescue corps of Pictou County and several men from Cape Breton with their breathing apparatus and other fire-fighting equipment, spent the week helping the miners of Inverness to fight a fire in the lower workings. This is the third outbreak of fire in that section of the mine. Progress had been made, but up to the time of writing the fire was not walled off.

The coal output of the United States continues to rise, slowly and steadily. Last week the production of bituminous coal was over 11 million tons, and of anthracite, over 2 million tons.

The many friends of Mr. W. W. Sayers, of the Canadian Link-Belt Company will be glad to learn of his promotion to the position of Chief Engineer of the Company's Philadelphia Works and Eastern operations.

Rich ore has been located at the head of Canyon Creek, Lardeau district B. C. Returns of two thousand ounces of silver to the ton have been secured. Five tons have been taken out and shipped to the smelter at Trail.

"SAFETY FIRST"

See your way clearly—
Ask if you don't understand—
Fix a dangerous spot—
Enlighten the new workman—
Think before you act—
You can do it—

First say to yourself—
"I am going to play safe"—
Remember to **THINK**—
Safety all the time—
That's the way it's done.

Beneath an "iron cap" long known at Skorovas, in the interior of Norway, 90 km. from the port of Namsos, there has been proved lately by diamond-drilling a compact deposit of iron pyrites of unusual purity to the extent of from two to three million tons, with much more in prospect beyond the range of the drilling. A railway to the vicinity of this deposit is in process of construction.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertiserswill be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eigthpage, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale,Que., who can in all probability, refer them to proper sources

EDITORIAL

The chief and greatest value of gold mines—especially in a new and unexplored country requiring people to work and develop its reproductive [agricultural] resources—lies in its power to attract such people rapidly and in such numbers as no other inducement will succeed in accomplishing.—A. R. Selwyn—1897

THE BEST IMMIGRATION AGENT—GOLD

It is by no means a recent discovery that Canada needs a vastly increased population, and that it is settlers on the land that are principally required. There are periodical fluctuations in the interest of the public in this all-important question, and the action (a rather reaction) of our public administrators fluctuates accordingly. At present we are on the top of a wave of interest, and our public officials, after years of inattention, are preparing to conduct an active campaign designed to help in populating the open spaces of our land. The effort put forth by a handful of public-spirited Canadians in high position on behalf of this problem, backed as it has been by the public press, gives promise of bearing fruit in the near future.

The Canadian public is being informed not only of the country's need, but of the various ways and means of meeting this need. On one point, however, public speakers and the public press have, in general, failed to make clear the facts. The importance of an active mining industry in aiding a rapid and permanent settlement is seldom gauged at its true value. Contemporary events, as well as the history of a century back, demonstrate that the establishment of a mining industry, and particularly of a gold mining industry, is one of the surest means of attracting settlers to the vicinity.

The reasons for the potency of a gold camp in inducing settlement are not far to seek. First of all, the very name of gold attracts men irresistibly, and among those that approach the spot where it is found, many are fated to clear and till the arable land round about rather than to work in the mines. Then the operation of a group of productive mines ordinarily induces the building of a railway, the prime essential for settlement in these days. The mines usually provide work for settlers at certain seasons of the year, particularly during the years of their first development, and, if they are long lived, find a recruiting ground for young miners in the farming community. The mining camps provide one of the best possible markets for the products of near-by farms.

This intimate relationship of mining and land settlement presupposes the occurrence, side by side, of workable mineral deposits and arable land. The two are not associated invariably; but in Canada there are few mining districts where at least small numbers of settlers cannot gain a good livelihood. Many of the fertile valleys of British Columbia, now adding largely to the wealth of the province and of the Dominion, would still be uncultivated were it not for the mines on the hillsides above. It is doubtful whether there would be now any settlement whatever in Northern Manitoba were it not for the promise there of mineral production.

It is in Northern Ontario and Quebec that we have the clearest demonstration of the efficacy of mining activity in promoting settlement, as well as the greatest opportunity for its profitable application. For four hundred miles — the width of the province of Saskatchewan — the National Transcontinental Railway runs through the Great Clay Belt. This belt of land is arable throughout the larger part of its extent —an area twice the size of the prairie part of Manitoba. At numerous points throughout gold has been discovered, and at two points on its southern edge, astride the Ontario Government Railway, productive camps have been established — Porcupine and Kirkland. There promises to be another gold camp sixty miles to the east, in Quebec, which will draw the railway northward from Temiskaming to the Transcontinental Railway, thus intersecting Quebec's portion of the Great Clay Belt.

This conjunction of arable land and gold deposits is a fortunate one for Ontario and Quebec, though it is a nuisance to the miner. Throughout almost the whole of the gold bearing area, outcrops of rock are so few that the prospector is hard put to it to make a find. That so much has been found in spots of this description speaks well for what intensive development will disclose. Meantime, the clearing and settling of the clay belt will proceed at a pace commensurate with the growth of the mines. The value of this [illegible] in the long run, far exceed the value of all the mines will produce, but to the mines must [illegible] for a part of this value.

It is incumbent upon those who [illegible] land settlement and immigration [illegible]

more clearly than they do the value of mineral development as a means to their end. The public press should be instructed in the facts of the case, and then it will, with little urging, exert its undoubted and powerful influence in favour of this rapid, sound and sure means of attracting immigrants and placing them where we need them most—on the land.

CANADA INDEPENDENT IN ZINC SUPPLY

In discussing the prospects for a zinc industry in Quebec, two weeks ago, we stated the supply of this metal for eastern Canada is imported, and that it is doubtful if zinc could be obtained economically from British Columbia. This conclusion was based on facts that are now completely superseded and no longer obtain, and our assumption is most decidedly in error. We have learned since then that the zinc produced at Trail not only supplies the small local demand in British Columbia and provides for the export of considerable quantities to the Orient, but also supplies eastern Canada with all it needs, and has commenced to break into the European market. The fact is that, except for odd lots of small dimensions that find their way into the country mainly by accident, the Trail smelter provides Canada with the whole of her requirement in zinc, and a large amount for export as well.

It is a series of metallurgical researches of outstanding importance in the history of zinc smelting and refining that has given to the Consolidated Mining and Smelting Company this outstanding position in the world's zinc market. These researches were conducted and then applied commercially principally during the war period and the years immediately preceding. When the company was released from its obligations to the Imperial Munitions Board soon after the war, it was in a position to seize the markets for zinc that it now holds. It seems probable that, with the completion of the new concentrator at Kimberley, the phenomenal ore-deposits of the Sullivan Mine will provide the basis for further additions to the markets for Canadian zinc.

COOPERATION AND PROGRESS

Slowly and painfully are certain members and adherents of our mining fraternity learning that the spirit of co-operation is one that best serves the needs of every man's pocket, as it does the needs of the mining industry and of the world of affairs at large. We have in mind particularly the "whole-hog" attitude that has prevented the development of so many prospects, retarded the growth of many a nice little mine, and blocked the successful operation of properties with ore-bodies too lean or of insufficient size to be worked alone. Happily, this attitude of mind is changing rapidly, and now it is no longer phenomenal to find a prospector ready to share the chances of success with the man who puts up the money for development, or to find neighbors sharing the benefit of a central shaft or of a common mill.

The progressive and sound viewpoint can best be demonstrated by examples. The original Elbow Lake find in Manitoba was of such phenomenal richness at the outcrop that the terms asked by, and granted to the owners for an option were in keeping with the realization of ore that would set the world agog with interest. Naturally and inevitably, these high-pitched hopes failed to materialize, the investors declined to take up their option and the district got a "black eye," after many a slim bank account had been reduced by the dishonest operations of boomsters who took advantage of the wave of excitement. Now, under a co-operative agreement, the property is being developed, quietly and consistently, with good prospects of success. The pity is that the original terms were not such that the original operators could have carried on with this work, with a great saving in expense and lost motion.

More recent examples are furnished in Northern Ontario. By taking over the Silver Cliff, which adjoins its Colonial property at Cobalt, Continental Mines adds a mill to its equipment and some promising ground that can be explored and developed from the new Colonial shaft. The Silver Cliff mill and mine have long been idle. We may assume safely that the terms of the lease arranged are mutually advantageous. The Continental Mines management have shown the same clear grasp of the benefits of cooperation in their treatment of the ground they now hold in the Kirkland Lake field. The development of this ground would have been long delayed, and indeed might have been postponed indefinitely, had not the chances, good, bad and indifferent, of the whole long line of claims been lumped with the assurance that the average value disclosed on development would prove remunerative.

The latest instance of this progressive spirit is furnished in the south of the Cobalt silver field. The old Beaver mine, which has failed to carry the financial load it was called upon to bear, is to be operated in conjunction with the adjoining Prince and Badger properties, the Beaver mill being available to treat the ore in prospect. The profit-sharing basis upon which the Coniagas proposes to operate these properties shows the spirit of cooperation in the highest degree.

Anent these examples of progress made possible by the give-and-take spirit that is displacing the ancient (but not honourable) attitude of exclusiveness and insularity, it is pertinent to mention the impasse in the power situation at Porcupine. Hollinger officials have announced that the terms of lease offered them for the water-power they proposed to develop on the Abitibi River are such that they cannot accept them in justice to the share-holders, there being no assurance of a continuous supply of water from works on the

river above under the terms proposed. No statement of the other side of the case has been made as yet by the Ontario government. Meantime we deplore the complete lack of managerial ability and of the spirit of cooperation in the man or men, whether representing a private corporation or holding public office, whose decisions are clogging the wheels of progress. The impasse reached in these negotiations between representatives of the Ontario government, the Hollinger Mines and the Abitibi Pulp and Paper Company, will bear hard on the reputation of one or other of them when all the facts are disclosed.

AN HONEST PROSPECTUS

We have received a copy of the prospectus of Stabell Gold Mines, Limited, whose property is in Dubuisson township in the upper Harricanaw district of northwestern Quebec. The property is described as a prospect of unusual promise, and the facts of the case are plainly given, without colour or exaggeration, by mining engineers of the best reputation. The arrangement by which it is proposed to raise the money required for further development of the properties is rational and sound, and we are convinced that investors are assured of a "square deal" and a "run for their money" in this case, provided the direction of field operations is as sound as the method of raising money. It is distinctly encouraging to find this evidence of a growing appreciation of sound financial methods in preliminary mining development.

Since writing the above, we have read with interest and with pleasure the "Montreal Gazette's" comment under the caption "Stabell Gold Prospectus Refreshingly Free from 'Come on' Features." If more of our responsible daily newspapers made it a habit to discriminate between genuine and illicit mining stock flotations, and then to uphold publicly the true and expose the false (or ignore these latter, which would be almost as effective), they would be performing a notable service not only to Canada's mining industry, but to their own readers.

EDITORIAL NOTES

Professor Mickle's letter, which we publish today, indicates one of the undoubted pitfalls into which Mr Campbell fell in his recent comprehensive study of Canadian mining statistics. We wish, however, to revert to the fact that Mr. Campbell's research on this subject is an unusually valuable addition to the information available, and we hope that it will stimulate further constructive study of the fundamental conditions of mining in this country.

Reports from the Annual Western Meeting of the Canadian Institute of Mining and Metallurgy in Vancouver on November 15th and 16th, and the subsequent excursions, go to show that it was unusually successful. The attendance was large and there was animated discussion of a number of important questions, as well as the presentation of numerous technical papers of prime interest. Our British Columbia correspondent has sent a full account of the sessions, which appears elsewhere in this issue.

On November 19th, there died in Boston, at the age of eighty years, a man known by name to every Canadian engineer, Christian Louis Berger, founder of the well-known firm of instrument makers. He was a man who put into the products, first of his hand and then of his factory, the character that was his own. He was born in Stuttgart, Germany, determined early in life to be a maker of fine instruments, and came to America after having served a thorough apprenticeship in his native city and elsewhere on the Continent and in England. On this continent he reaped the full reward of thorough workmanship and sound business management — qualities that are certainly more nearly universal in Europe than in America. The "instruments of precision" that are now so widely associated on this continent with the name of Berger may well give to many an engineer who uses them the secret of professional success.

DRURY RURAL

(A handbook distributed by the Ontario Government contains about 20 times as many pages devoted to farming as to mining. Hence this verse.)

I always did admire the farm,
The barns and byres and cattle;
For me the country has a charm—
(You know this kind of prattle.)

I know the farmer's merits and
The hard road he must travel;
Full often he inherits land
That's mostly rock or gravel.

But, granting all of this is so,
Suppose his virtues trebled,
He's not the only stone, you know,
With which the beach is pebbled.

So, Mister Drury, listen while
I make a little statement
Without a hint of hidden guile,
Or truth's minute abatement.

We love the farmers and their work,
We love them as our brothers;
But, Mister Drury, though it irk—
Pray don't forget us others!

C. M.

Norman Oil Fields*

MACKENZIE RIVER AREA

by GEO. S. HUME

As was anticipated owing to the difficulties of operations in a distant field, development in the Norman area will be comparitively slow. Last summer the Imperial Oil Company undertook the drilling of three wells previously started and deepened the original well. Great disappointment had been expressed by some interested in the oil fields that the original well, which promised so much in the beginning, had gradually declined until its production had almost ceased. It was not realized by the public in general that when the gusher "came in" the bottom of the well was still in soft shale formation. Cavings into the hole were inevitable and a gradual blocking of the flow resulted until the well stopped production. With these facts in view the Imperial Oil Company last summer deepened the well with most gratifying results. A flow of oil was obtained which amounted to 60 to 70 barrels** per day. The well is now capped aand the oil is being used as fuel in other drilling operations.

Drilling Program for the Winter

Difficulties in drilling caused the temporary abandonment of all three of the other wells, but two drilling crews are spending the winter in the Norman area and the results from these wells ought to be available next summer. Two of these wells, one on Bear Island in the Mackenzie River, known as the Bear Island well, and the other on the west side of the Mackenzie, the "C" camp well, are so situated with reference to the original well that a great deal of information about structure will be available from the records in addition to what can be obtained from surface exposures of rock. The rocks are dipping in a general westerly direction from the Norman or Discovery Range to the east of the well, so that both the Bear Island and "C" camp wells are further down the dip than the original well the "C" camp well being more so than that at Bear Island. This means that these wells will have to be drilled deeper than the original well in order to reach the same productive horizon, the increase in depth being dependent on the amount and direction of dip and the distance between the wells. From surface exposure the dip can be measured and as the distanec is known the depth to which each well will have to be drilled to reach the productive horizon of the original well can be caculated. This has led to the conclusion that in neither the Bear Island nor the "C" camp well has the horizon yet been reached that is producing in the original well, in spite of the fact that the original well is less than 1000 feet deep and that of "C" camp more than 1700 feet.

Important Bed of Sandstone Discovered

There is another factor of importance bearing on the oil situation in this district. As has been intimated, the wells are being drilled in a shale known as the Fort Creek formation. Hitherto it was not known that this shale contained any sandstone members of any thickness. In the course of the summer's work for the Geological Survey a sandstone member of 50 to 75 feet was found in the shale formation and several hundred feet above the "Beavertail" limestone on which the shale rests. This sandstone outcrops on several of the streams between the Mackenzie and the Norman range of mountains, eight miles northeast of the discovery well. A calculation based on the available information seems to show that the depth of the discovery well is now such that this sandstone member has been reached. If such turns out to be the case the flow of oil from this sandstone will be much steadier and give a longer life to the well than could be hoped for from a shale. The shape of this sandstone member is as yet undetermined. It may be that it is in the form of a lense, in which case it might not extend over a wide area, or it may be more in the form of a continuous sheet, in which case it certainly will be encountered in the other wells. As is commonly known, oil tends to accumulate in the more porous beds; hence the sandstone will be a favorable receptacle which will greatly add to the possibilities of production.

Cretaceous Rocks May Hold Oil

The oil in the Norman fields has all come so far from rocks of Devonian age and all the wells have been started in Devonian formations. On the west side of the Mackenzie in the oil district there is a great thickness of Cretaceous deposits overlying the Devonian. Before the period of Cretaceous deposition, the Devonian was a land surface subject to erosion, so that it was unequally worn away. On its submergence again, the Cretaceous sediments were deposited on this eroded surface with the result that the Cretaceous overlies different formations of the Devonian at different places. The contact between the Devonian and the Cretaceous is thus very irregular, or is what is known as an erosional unconformity. Subsequent to the Cretaceous deposition, mountain-building movements took place and the rocks were thrown into the folds with which the accumulation of oil is associated. The period of this mountain-building may have a district bearing on the oil problem of some areas because it means that the Cretaceous as well as the Devonian strata are folded. The Cretaceous formations consist of sandstones at the base overlain by a considerable thickness of shale, which would form a very suitable cover for the retention of oil. It is not impossible, therefore, that oil pools may be present in the Cretaceous as well as in the Devonian.

Bosworth Formation Favourable to Oil Accumulation

Overlying the Fort Creek shales which now form the productive oil strata a series of greenish sandstones and shales known as the Bosworth formation. The sandstone members of this formation produced small flows of oil in the discovery well almost from the beginning of drilling. On the east side of the Mackenzie in the vicinity of the wells between the river and the Norman range, these sandstone and shales are the surface rocks so that any oil originally in them has had a favorable opportunity to escape making the numerous

Letters From Porcupine--IV

OUTSIDE STUFF

A rebellion is not a revolution until it is successful. Similarly reformation is a schism until it carries the majority with it.

The owners of mining properties in the township of Deloro are no longer apologetic or explanatory.

Amongst a number of claims that I visited in that township, I wish to refer first to the Ankerite, because there I spent much time most profitably and informingly.

Before touching my notes, taken on the Ankerite, I wish to advert to the *Canadian Mining Journal's* editorial notice of the property to the effect that it is as promising a Porcupine property as there is that has not yet produced bullion. In this opinion I concur, also in the statement that it needed no such advertising as it unfortunately received. To that it may be added, in fairness, that the mining engineer, whose name has been and is now identified with the Ankerite, was totally opposed to such advertising methods, and that the advertisements appeared without his official sanction or knowledge.

The purposeful reopening of the Ankerite is the result of perseverance in the face of much discouragement and (as is usual in many such cases) of overt and covert opposition. However, these things have nothing to do with it, or else just now.

Nothing could well be plainer than the geology of the Ankerite as developed by surface stripping, crosstrenching and sampling. It is not my intention to mention average values etc., because this is not the place wherein to advertise any enterprise. But I do intend to mention my belief that the exploratory and prospecting efforts expended on the Ankerite were exceptionally well directed. Every step had a direct bearing on each other step. Moreover, the future development of the Ankerite will be a source of guidance to operators in the surrounding region.

Nowhere that I know of, overground, are the successive phases of Nature's ore making processes so easily traced as on the Ankerite. The direct and the indirect effects of porphyry intrusions are visible. The difference in the character of the vein filling and the mineralization of the schist is apparent. Here, also, the significance of the presence or absence of tourmaline is obvious, or was made obvious by work done.

These and other points will be elaborated in the course of a separate article which will be submitted to the Editor at a later date. My present purpose has been accomplished in drawing attention to the high quality of the mining engineering on the property.

* * *

An employee of a Timmins business firm invited me to inspect his mining claims. He could show me, he said, a body of schist 200 feet wide and of indefinite length, all of which would pan "colours." The property lay about ten miles from the town. I had seen several others presumably of the same kind—staked for schist and for schist alone. So I did not go. It is the most ungrateful task in the wide world to tell an owner that you do not think much of his property. No matter how right you may be, the owner wants admiration or nothing.

It was a relief, therefore, to hear first hand details of mining being done in the Night Hawk Lake area. Here rational development is succeeding rational preliminaries. At Three Nations, also, most encouraging results are being obtained. My reference here is entirely to the mining aspect of the case. The implied reservation should be obvious enough. In any case there is reason to hope, perhaps to expect, that both these outliers of Porcupine will "arrive."

* * *

In the course of a walk over mining claims south of Timmins I came upon a cabin of particularly neat construction. Everything about it was workmanlike. It was "chinked" in a comforting manner. The cooking arrangements were right, the dishes were clean, the floors were tight and well swept, home made brooms were bestowed in a corner, and altogether it gave me a desire to live there for a week or so. I learned that the architects were Finns who, working with the axes and knives that they had to hand, had turned out a job that it was a pleasure to see. It was a sweet contrast to some of the shacks that I have seen in Porcupine and otherwere.

* * *

To get down to the specific after this interminable rambling I take this opportunity of recommending to all corporations and individuals who intend to become interested financially in Porcupine, the policy of keeping a competent observer on the spot. Whilst the right choice of man granted, it is as sure as anything human can be that his time can be well spent, not so much in the formal examination of properties and prospects as in gathering in and sizing up and boiling down information of all kinds. That he will come on really good [illegible] is almost inevitable.

Not all men are fitted for this office, but many are.

Such a channel of first hand facts and impressions can be made of inestimable value. But the chance will not last forever. My belief is that it will last an extremely short time.

* * *

My imprecations on those persons who accumulate meanings into what one writes [illegible] highly

---

seepages known in this area. To the west of the Mackenzie, west to the Caracajou Mountain range, these rocks are mostly overlain by the Cretaceous deposits already referred to; hence, if suitable structures can be located in this area the chances of obtaining oil seem very favorable, either from the sandstones below the impervious Cretaceous shales or from the deeper Bosworth sandstone of Devonian age. Such a favorable condition in the sequence of strata is not always present where Cretaceous deposits occur because, as has already been pointed out, due to the erosion prior to the Cretaceous deposition, parts of the Devonian are lacking and Cretaceous beds lie directly on other members of the Devonian unsuitable for oil accumulation.

A detailed account of the stratigraphy and structure of the Norman Oil Fields will appear later in the Summary Report of the Geological Survey of Canada for 1922.

innocuous Letters have been misconstued by a number of readers, although I have sterlized, Pasteurized, and otherwise rendered them germless. Several signed and one anonymous communications have have been sent me warning me of the error of my ways. Now that would be all very well if I had east discretion to the winds and had written all that was on my mind. But a feller needs a friend when he has conseiously had before his mind's eye the fear of God, Editor, and reader and still is found fault with. It would seem almost better not to write at all: a conrse that one correspondent earnestly pressed upon me. I am giving his recommendation serious consideration.

* * *

I recall a gathering of mining men in the Shnniah Hostel in Pottsville, years and years ago. It was a very miscellaneous gathering indeed. Bill Davidson was there. So also were brokers and others from Toronto, New York, Montreal and other notable cities. Canadian, English, and United States engineers, promotors, prospectors, and "capitalists" were well represented.

It was eventide. Several games of chance were being played, or worked. Some of the conversation was strictly not far parlor consumption. The Hostess had produced her expected series of unexpected sensations. The crowd was resolving itself into groups. Suddenly a prospector, moved by the spirit of prophecy, took the floor—which was really another man's chair. In a brief but impassioned speech, he told us that the day would come when a thousand stamps would thunder in Porcupine—and that we could all go to H-ll if we didn't believe him!

The prophetic prospector is in another world. Neither he nor more than a half-dozen of his fellow prospectors made a stake. But his prophecy came true. Most of ns thought that he was talking the hottest of hot air.

This may not prove anything at all. On the other hand it may.

J. C. MURRAY

TITANIUM PRODUCTS AND THEIR DEVELOPMENT *

About 1830, Archibald MacIntyre, David Henderson and associates purchased a large tract of land in Essex County, New York, in the heart of the Adirondack Mountains. This deposit was brought to their attention by Indians, who had visited a small forge in Keene Valley, where iron ore was being smelted. The red men told of a great body of similar material forming a dam near the head waters of the Hudson River. The white men accompanied them to this spot, and having examined the surrounding country carefully, soon arranged for a purchase totalling several square miles.

Despite the extreme ruggedness of the country and the fact that these ore deposits were 40 miles from Lake Champlain, these hardy pioneers in 1840 erected a small charcoal furnace. This furnace was remodelled in 1848, and in 1852 a much larger furnace (11 feet 6 inches x 48 feet) was built and operated successfully, using titaniferous iron ores carrying as high as 18 to 20 percent titanic oxide. The operation of this furnace was continued until 1856, when, for various reasons, principally lack of transportation, its operation was discontinued.

This old furnace, still standing, in fairly good state of preservation, was recently carefully examined by experts. Their report to the present owners of the property was conclusive that no serious difficulties had been encountered in the smelting of titaniferous ores. The lining shows no sign of scaffolding: the hearth was blown out clear to the bottom, and the slag shows evidence of considerable fluidity.

As years rolled by there grew up a prejudice against the use of titaniferous ores in blast furnace practice, and about 1890 Dr. Auguste J. Rossi, whose name has since become well known because of his work on titanium, was engaged to demonstrate that titaniferous ores could be successfully used in blast furnace practice under more modern conditions. He produced an alloy of iron and titanium, which it was found later was a most efficient deoxidizer and cleanser for the treatment of steel because of the great affinity of titanium for both oxygen and nitrogen, and also because of the property of titanic oxide, formed by the oxidation of titanium, of combining with other slags and oxides and increasing their fusibility, thus effecting their release from the steel by rising to its surface and combining with the slag. The present extensive manufacture and use of ferro-titanium is a result of this pioneer research of Dr. Rossi and indirectly of the early work of MacIntyre, Henderson and their associates.

Some ten or twelve years ago, in the research departments of The Titanium Alloy Manufacturing Company, at Niagara Falls, New York, the extreme opaquing or hiding power of the white pigment, titanic oxide, when mixed with oil was noted. It was found, however, that to manufacture titanic oxide to compete with other opaque white pigments would be practically impossible. Further research demonstrated that a composite pigment consisting of only 25 per cent of titanic oxide thrown down on a base of precipitated barium sulphate, probably because of the wonderful fineness of the particles and maximum distribution of the titanic oxide, actually had approximately 80 percent of the hiding power of a pigment consisting of 100 percent titanic oxide.

This research followed by careful tests to demonstrate the availability of this composite titanium pigment brought out the fact that such a pigment had greater hiding power than any white pigment known, was exceedingly inert to various vehicles (oils, etc.) and other pigments, was non-poisonous, and had many properties which made it unique among pigments. After several years of research development, this pigment is now being manufactured in large quantities in this country and Norway.

Already many other uses for the element Titanium have been suggested and no one can safely predict the limit of this development, which originated 75 or 80 years ago, when a few venturesome men attempted the seemingly impossible task of manufacturing iron in the wilderness.

* Research Narrative 45, Engineering Foundation.

Users of anthracite coal will be glad to know that the production in the week ended November 18th was 2,191,000 tons, a record that has been exceeded only once in the last six years. The production in previous weeks was not far below this mark, and it is expected that the high rate of production will continue throughout the winter.

Annual Western Meeting C. I. M. & M.

REPORT OF IMPORTANT MEETING IN VANCOUVER

The opening day of the annual western meeting of the Canadian Institute of Mining and Metallurgy, which was held at Vancouver B. C. from the 15th to the 17th of November inclusive, was somewhat unusual because of the fact that there were important and interesting discussions on two matters of policy in addition to the customary formalities and reading of technical papers.

When W. R. Wilson, president of the Institute, who also is the president of Crow's Nest Pass Coal Company, called the gathering together he found assembled several hundred representative mining men of Canada. While those associated with British Columbia industry and with that of the neighboring province of Alberta predominated in number, there were delegates from many other parts of the Dominion, as well as distinguished visitors from the United States.

In sending greeting to the meeting, Mr. Sloan, Minister of Mines spoke of mining conditions optimistically. The industry had been passing through dull times. The over-accumulation of metals during the war and the ensuing depression had not been altogether overcome. Prices still were comparatively low but the tide was turning. There was a healthier tone to the market. British Columbia was on the up-grade. A revival in the Kootenays was presaged. The indications were clear. The wonderful development in the Portland Canal District, the increased interest being taken in the placer mining areas of the Province, and the enterprise of several of the larger corporations in making large investments in development and in plant anticipatory of future large scale operations, were matters that spoke for themselves. He declared that, in spite of conditions that had hampered the coal mines for several months, it might be expected that the coal output for the year would be in excess of that of the previous year.

The President's Address

Mr. Wilson's address struck a high note. It was a pleasure to see so many present and among them members from distant parts. That was the proper spirit. Selfishness was at the root of all evil. No member would get more out of the Institute that he put in. The reason for its being was the facilitation of the interchange of ideas, that those having common interests should help one another. He trusted that that principle would be generally accepted and applied.

E. W. Guernsey, chairman of the British Columbia Division of the Institute, followed with an endorsement of the sentiments of the president in which he, too, extended a general welcome to those present.

Discussion on "Institute Policy"

A summary of a paper prepared by G. C. Mackenzie, secretary of the Institute, on "Institute Policy" was submitted by Prof. R. C. Wallace, of the University of Manitoba, and gave rise to much discussion. He advocated the adoption of the "open door" in connection with membership. All interested in the mining industry should be permitted to join. The scope of the Institute's activities should be broadened. Principles of democracy should prevail. Hard and fast rules in respect of technical or other qualifications, with the exception of an honest desire to be associated with the Institute coupled with respectability, should be removed. Thus the strength of the organization would grow, its influence become greater and its future assured.

The sweeping radicalism of Mr. Mackenzie was combatted by H. G. Nichols, who presented a paper entitled "The Institute Idea," and by J. D. Mackenzie, of the Canadian Geological Survey, Vancouver. Mr. Nichols argued that an organization of technically competent men whether their knowledge came from college training or from practical experience, was of great value to the industry. Collectively they spoke with force and authority. Mere numbers was not a source of strength to such an organization as the Institute. If the policy suggested were adopted the result would be the loss of character and he, for one, would look forward to the opportunity, which he was sure would come, of becoming a member of an organization that would be a more fitting medium for the interpretation of the sentiments of those whose attainments qualified them to speak for the technical and scientific branch of the industry.

Amendment of By Laws Proposed

J. D. Mackenzie's views were much the same as those of Mr. Nichols and he put them in the concrete form of an amendment which, no doubt, will be presented to the members as a whole at a later date. He would have the membership divided into three classes, viz., full members, associates, and students. The first would have to measure up to a specified technical standard, the second would be open practically to all interested in mining sufficiently to wish to become identified with the Institute and the third, of course, identifies itself.

Opinion seems to be fairly evenly divided as between the two proposals. Some asked where the discussion was leading, whether there was any prospect of a decision being reached by the meeting. To this it was explained that the issue would have to be put to the entire membership and be decided by ballot.

It developed that, after all, the question is largely one of finance. The Institute finds itself embarrassed. There is an immediate need of action, either in the direction of increased membership or of an addition to the dues. The cost of the issuance of the issuance of the monthly Bulletin, it was shown by a member of the Council, runs into $6,000 per annum and in this connection there was a suggestion that to make the *Canadian Mining Journal* the official organ of the Institute was one path out of the difficulty.

Mr. Rickard on Technical Journalism

After luncheon under the auspices of the Mining Bureau of the Vancouver Board of Trade, an address was delivered by T. A. Rickard, consulting editor of *Engineering and Mining Journal Press*, on "The Duties and Privileges of Technical Journalism." As usual, Mr. Rickard clothed his subject with phraseology of such felicity and anecdotes of such pointed interest that he held his audience attentive throughout. He dealt with the responsibilities of the editors of the technical journals both to their advertisers and to their readers. In [illegible] the former these publications must be read and [illegible] read they must be instructive, abreast of developments to the point of news, absolutely reliable and [illegible] independent in their comment. To be of [illegible] those who read them as a medium of presenting [illegible] good to possible purchasers they must be all that was [illegible] defined. To be read they must measure up to these standards, and

in addition, be fearless in destructive criticism when warranted and frank in constructive criticism when merited. Mr. Rickard was strong in his denunciation of the competition met with by the legitimate technical press from so-called official organs of the Institutes of the United States. He observed that much the same situation was met with in Canada in the relationship of the Institute and the *Canadian Mining Journal*. If the Institutes destroyed the technical press they would destroy one of their best friends.

Mine Taxation

"Government Taxation and the Mining Industry" was presented by Valentine Quinn, of the Granby Consolidated Mining and Smelting Co. Ltd., who had reference, for the most part, to the situation in British Columbia. He first discussed the failure of the government to permit the deduction of interest on money borrowed outside the Province in arriving at a basis for taxation. In this connection he declared that this Province was far from being a money centre. With one possible exception it was both geographically and financially as remotely situated as any part of the Dominion. "Unjust as this ruling is, however," he continued, "it is mandatory, and an important element in the chaos of tax inconsistency responsible for this great Province shuffling along anaemically instead of striding ahead like a giant in its strength."

He added: "What is needed is a change of viewpoint on the part of governmental authorities, a positive phychology, friendly co-operation; a little more of the spirit of giving, and less of the spirit of taking; a determination to use, as the basis of assessment, the real profits of industry as the constant factor and to allow the rate of assessment to be variant, in accord with the actual minimum requirements necessitated for the maintenance of responsible government."

Mr. Quinn asked that the Income Tax Act be re-written in regard to the allowances made for depreciation, including short-date amortization of war expenditures and obsolescent allowances, depletion, development, and interest on money borrowed outside British Columbia. Fault also was found with the principle of permitting allowances at the discretion of the Minister of Finance. Public accountants could be charged with the responsibility of certifying under oath to the reasonable and fair claims made for deductions, and by means of proper legislation responsibility could be placed upon them for justifying such claims when challenged by the Surveyor of Taxes.

References to the Provincial Government, however, were not all of a critical nature. They were paid a tribute for their proposals for the international coordination of safety-first measures and for the appointment of District Mining Engineers, "whose activities search out the most remotely situated prospectors and operators. To these isolated pioneers is furnished, free of charge, technical advice of the most valuable kind."

Depletion of Ore Reserves

Hugh R. Van Wagenen, of the Canada Copper Company continued the discussion, presenting a synopsis of a paper by R. V. Norris on "Depletion." Mr. Norris set down two fundamental principles for valuation, first that the total value of a property at any date is the value of the future earnings of such property discounted to the date in question, and second that the value of the mineral in the ground, at any date, is the total value of the property (as worked out under the first mentioned principle) less the value of the present and prospective capital expenditures for plant development and equipment necessary to recover such mineral discounted to the same, above stated, date."

Mr. Van Wagenen considered Mr. Norris' methods which he elaborated at some length, as both logical and practical. The Canadian Government already recognized the advantage of basing depletion on net earnings instead of on mine valuation and had adopted that procedure. But the provincial government's method of fixing the percentage for deduction was empirical rather than scientific. In Canada the gold and silver mines were allowed to deduct 50 p. c. of their net earnings for depletion and compute the tax as 10 p. c. of the balance of the net earnings. Copper, lead, and zinc mines were allowed to deduct but 25 p. c. of the net earnings as an allowance for depletion. For coal mines the allowance was about 10 cents a ton. Obviously there was nothing scientific about this. In it there was expressed the opinion that, as between a gold mine and a lead mine, there was less assurance of life in the former than in the atter; the more risk attends the investment of capital in the precious metal than in the base metal mines. "In general" he added "this many be true, but in specific cases it might easily be the reverse of the fact. Norris' method reduces the question at issue practically to the tonnage available, because the other factors are the actual performance of the year just ended and are not assumptions of tonnage handled or profits made. The question of available tonnage is something upon which reasonably close accord can be reached between mine owner and government tax official. An error in the estimate, either under or over, could be corrected at the time when the extraction reached figures which exceeded the estimate or when they fell short of it."

Mr. Van Wagenen did not think it was necessary that the Province should have its own valuators and its own investigations. The Dominion findings should be accepted and the Provincial tax levied as an increment to "that which we pay to the Dominion." This would eliminate the considerable present departmental machinery and expense. He commended the 2 per cent. Mineral Tax. This was a provincial tax based on the theory that the exploitation of natural resources depletes those resources and that the Province should receive a certain amount of money on these wasting assets as they are removed. This was right and such collection should be made regardless as to whether the metal or the coal miner, or the lumberman made a profit. This tax was today a substitute, in part or in whole, for the Provincial Income Tax. Under his plan the tax woud remain as it is in this respect.

Taxes and International Trade

One of the most important of Mr. Van Wagenen's points was made in conclusion and was expressed as follows:

"Fundamentally it is right that the mines be valuated for taxation by the Dominion tax authorities because mines are, in a sense, national rather than local, because they must compete with mines of other nations in markets common to all nations and at points perhaps thousands of miles away from the borders of the Province. It is a matter of the city's own business what tax they put, say on a street car system, because if they advance it to a point where the tram company, in order to make ends meet, must advance the fare from 5 to 6 cents, it is only the people who use that car system who are affected or who care. The tram company keeps on operating just the same and the bondholders continue to receive the interest on their investment. But if a provincial government taxes a copper mine to the point where that tax represents another cent or two added to the cost of production, the additional burden might prevent successful

competition with the large producers of the United States, of South America, or of Africa."

Discussions with Provincial Authorities

In the informal debate that ensued it developed that a committee of mining men had waited upon the Provincial Government with reference to allowances for depreciation and depletion and had received a very attentive and sympathetic hearing. This was testified to by H. Mortimer Lamb, the secretary of the meeting; R. Randolph Bruce, of the Paradise Mine, Windermere; and T. W. Bingay, of the Consolidated Mining and Smelting Co. Mr. Bruce said of the matter of allowance for interest on money borrowed outside the Province, that it must be remembered that this was not a child of the present but of the previous government. The only difference was that then the rate was not great enough to trouble those affected. Taxation increases had made it a point of importance. It also was to be borne in mind that this principle was applied not alone to the mining but to all other industries in the Province. It could not be said that the mining industry was being discriminated against or that it was being particularly unfairly treated. Depreciation and depletion allowances had been made since January 1, 1921. Failure to make the Act retroactive, in respect of this amendment, no doubt did leave some companies, as stated, with considerable arrears of taxation. There was some present dissatisfaction with the method, or lack of method used in arriving at a just basis for these allowances. However, he was convinced that the government was alive to the necessity for action. Mr. Bingay's remarks were along much the same line. He did not take much stock in some of the more or less involved proposals of working out a system. The truth of the matter, he bluntly stated, was that, now that the government was moving in the right direction, it was difficult, owing to the variety of ore bodies being operated, their variety in character, etc., to offer advice, that in its general application, would be satisfactory.

This closed consideration of the subject, it being left with the understanding that negotiations and investigation would be continued with the authorities.

The Visiting Members

In addition to those whose names have been mentioned as having taken part in the discussions of the first day there were many visitors in attendance. Dr. C. Camsell, Deputy Minister of Mines, Ottawa, was given a warm welcome by his numerous British Columbia friends. He extended greetings from the Minister, the Hon. Mr. Stewart, and expressed his pleasure at returning to the Pacific Coast for a short visit. J. McLeish, Director of the Mines Branch, Ottawa; C. M. Odell, of Glace Bay, N. S.; Prof. Wallace of the University of Manitoba; J. A. Campbell, commissioner of Northern Manitoba; B. F. Haanel, chief of the Fuel Testing Department, Ottawa; Prof. J. A. Allan of the Department of Mines, Edmonton, Alberta, and included in visitors from the other side of the line, Messrs. L. K. Armstrong, J. G. Bradley, S. J. Butters and C. W. Merrell were some of the distinguished delegates. It may be said, by the way, that word was brought by those from Spokane, Wn., of the revival of activity in the Coeur d'Alenes. The growing market for lead and zinc and the better prices were having an almost magical effect in that district. All the big producers were operating again on a large scale and many properties that had been closed down were resuming work. Last fall difficulty had been experienced because of labor shortage. That condition had improved and general conditions were most encouraging.

Mr. Armstrong, of Spokane, was called upon at the opening of the Thursday morning session. He spoke of the pleasure it gave him to be present, of the work of Columbia District Institute, of which he is a member, and advised members to be up on their toes and taking a leading, rather than a following part, in the industrial and other problems of their countries in these days of unrest.

"Blue Sky" Laws

"Blue Sky Legislation in Manitoba" was the subject introduced by Prof. R. C. Wallace, of the University of Manitoba. He sketched the conditions in this regard in the prairie provinces of Canada. A form of "Blue Sky Law" had existed in Manitoba since 1911 while the Provinces of Alberta and Saskatchewan had followed suit in the years of 1916 and 1920 respectively. The object aimed at was not the hampering of industry but the prevention of the stacking of cards against the public by the dealer. Manitoba was not as yet a great mining district but it was a favorite ground for the flotation of companies. Forty six of the States of the Union had adopted legislation of the "Blue Sky" variety. Such legislation could be divided into two classes, that represented by the Fraud Acts and that which endeavored to prevent fraud by regulation before it developed. The latter was the form of law in effect in Manitoba. To obtain a charter a Company was required to appear before a Board or a Commission, to give particulars as to the property to be developed, what was paid for it, the personnel of the Board of Directors, what capital and what treasury stock existed, and so forth. If those in authority found the enterprise a reasonable and legitimate one the charter was issued and permission was given to proceed, but the stock was placed in the hands of a trustee and no promotion stock was allowed. Briefly that was the system followed and, while there were arguments against any interference with the investment of money in mining ventures, there was no doubt that it had saved Manitoba from the boom of 1914.

his Province there was a Public Utilities Board, which had to be satisfied as to the bona fides of all propositions involving stock flotation. An effort had been made to have the Board appoint a qualified engineer to report on such properties as were to be exploited. The approval of such a person, he thought, would be the public's best protection.

An Example of "Salting"

E. E. Fowler, who was Chairman of the session, was doubtful regarding the efficacy of any 'Blue Sky' regulations. Recently an incident had come to his notice that happened in the Kootenays. A man of wealth, but of no mining knowledge, had lost some thousands of dollars.

Mr. Shanks, of the Province of Alberta, said that he He had bought what he took to be a valuable gold quartz property. On it there were two adits, an upper and a lower, with a raise on one. A bucket of gold bearing ore had been raised to the upper level, shown to the intending buyer and, its richness being clear to anyone, had been taken away ostensibly to be thrown on the dump. Actually it had gone down to the lower adit and been brought to the surface again by the route of the upper adit. The operation had been repeated a sufficient number of times to serve the purpose of the owners. He asked whether it was possible to protect the public against this kind of utter foolishness.

Prof. Allan, of Alberta, emphasized the need of uniformity among the Provinces in "Blue Sky" law if it was to be effective. This point had been referred to by Prof. Wallace and he thought it well taken. The Manitoba law lost its value to a large extent when properties were

ted in the province could be fraudulently boomed in other parts of Canada. The same applied to Alberta and other povinces where such legislation had been enacted. There was need for a common Canadian law.

Mr. Rickard observed that while you couldn't protect the fool you could make it hard for the knave. He was of the opinion that no competent engineer would find any of the "Blue Sky" laws extant irksome. He though the Institute should support such legislation because every dollar that went into fraudulent proposals meant so much less for legitimate investment. He was inclined to think, however, that much more money had been lost through the over-capitalization of big companies than in "wild cats." He had in mind two companies on the Rand, South Africa, that had made a loss in four of five years for stockholders of $204,000,000 because of the gradual recession of the valuation placed on the properties.

The Metallurgy of Zinc

"The Story of Zinc" as given by Prof. H. N. Thomson, of the University of British Columbia, was a special treat both as to its informative and its intertaining features. He mentioned that since his last talk on complex ores there had been notable progress made in the metallurgical treatment of zinc ores. It was common knowledge that the Consolidated Mining and Smelting Company at Trail now accepted concentrates carrying 30 per cent. of zinc ore or more. As an illustration of some of the reduction difficulties he pointed out that the Company undertook to account for 85 per cent. of the valuable content when the material ran 50 per cent. or better, and to be responsible for somewhat less when it ran below that percentage in metal content. The speaker went right back to the methods of the ancients in traeing the evolution of zinc extraction practices. Coming down to modern times he dwelt on the comparatively recent realization of many of the new commercial uses to which the metal can be put. Figures were given showing the insignificant output of seventy-five or eighty years ago as against the production of around 1,000,000 tons per year at present. The development of smelting efficiency was indicated by the statement that the first plants required 20 tons of coal to produce one ton of zinc while those of today take only four tons of coal to make one ton of the metal. He sketched the steps that led to electrolytic process becoming an economic factor in the industry. In this connection the enterprise of the Consolidated Mining and Smelting Co. during the years 1913, 1914 and 1915 was referred to—activity that had continued with the result that new methods had been evolved that were of first importance to the operators of the Kootenay Districts of this Province.

Ore Testing Plant

The paper of Prof. S. J. Schofield, University of B. C., on "The Mineral Industry of B. C.," which has been previously summarized, created considerable discussion. This arose through the speaker's endorsement of the proposal for the establishment in the Province of an Ore Testing Plant. J. D. Mackenzie did not think that this was a matter of special importance. What did matter was the finding of the ore deposits, and metallurgists then could be depended upon to work out economic methods of treatment. As illustrating his point he instanced the Big Sullivan Mine, Consolidated Company, now the greatest producer in the West. Prof. Schofield thought that Mr. Mackenzie's illustration supported his argument. He had inspected the Sullivan years ago. One Company had "gone broke" over it. If there had been an Ore Testing Plant in the Province it was possible that the problem of the treatment of these ores would have been solved ten years earlier.

The Premier Mine

The Premier Mine, Stewart, B. C., was described by Dr. George Hanson, of the Geological Survey. He outlined the geological history of the mineral zone in which this great producer is situated. The circumstances leading up to the acquisition of a controlling interest by the American Smelting and Refining Company were detailed. Some account was given of the development underground and in the plant that has since taken place, several miles of tunnelling, a greater amount of diamond-drilling and much improved facilities for the mining, treatment and shipment of the ore.

Cariboo Lode Deposits

Prof. W. L. Uglow, University of B. C., was followed with close attention in his account of the quartz veins of Barkerville, Cariboo District. Reference was made to the recent exploration work of Mining Corporation of Canada on Proserpine Mountain. This had ceased and consequently the lode gold mining possibilities of the section had received somewhat of a "black eye." The professor questioned the justification of the conclusion that seemed to be generally taken. There were, he declared, two distinct series of quartz veins traversing the ridge of mountains of which Proserpine was one. One kind was large and apparently almost barren and the other smaller and, it would appear, of some considerable promise. The one intersected the other and he had no hesitation in saying, that, at the intersection, further exploration was fully waranted. He had taken some samples of these stringers and while unable to give assay returns, not yet having received them from the Ottawa laboratories, he was sufficient sure of his judgment to feel safe in making this statement. He maintained that all the indications were that the placer gold of the headwaters of Williams, Grouse, and other creeks of the section, which had produced great wealth in the past, was of local origin. It came, in his opinion, from the ridge of mountains referred to and it was only fair that something along this line should be said in view of the impression created by the cessation of the operations of the Mining Corporation. Certainly the veins described merited close investigation.

Moving pictures of the gold and silver mining industries of Ontario and of the asbestos industry of Quebec concluded the day's programme.

Papers on Coal Mining

Friday and Saturday were given over to coal mining and its problems. There were a number of papers in the morning, including "The Complete Gasification of Coal and its Bearing on the National Fuel Problem" by John Keller, of Vancouver; "The Development of the Coal Industry of Canada" by F. W. Gray, Montreal; "Progressive Coal Mining" by Geroge A. McHattie; "The Coal Mining Industry of Alberta" by T. A. Richards, District Inspector of Mines, Edmonton; and "Some Interesting Features of Modern Coal Mines" by R. R. Wilson, Victoria B. C.

In the afternoon there was an excursion to the coal mines of Vancouver Island, of which a fair percentage of the delegates took advantage. On Saturday also there was a visit by some of those interested to the collieries of Nanaimo, Ladysmith and Cassidy, Vancouver Island.

The meeting was pronounced generally one of the most successful in the history of the Institute.

The production of silver-bearing ore on Keno Hill Yukon Territory, this winter will exceed first estimates, according to recent arrivals from Mayo. Approximately 7,500 tons will be ready for a spring shipment from Mayo, it is thought. The Treadwell Yukon Company is working 100 men at Keno.

Statistics and the Canadian Mining Industry*

A REPLY TO MR. C. M. CAMPBELL'S LETTER.

BY PROF. G. R. MICKLE

To the Editor, Canadian Mining Journal.

I have read Mr. Campbell's letter in the *Canadian Mining Journal* of November 3rd., under this heading. I have no sympathy for statements that are not based on accurate observation and inference whether optimistic or pessimistic. If we are to act wisely we must first accurately observe and then draw the proper logical deduction. This is where it appears to me Mr. Campbell fails. The fallacy in his line of reasoning, I think, is shown in the following passage:

"I have been accused of being a pessimist; of holding a 'lugubrious brief'; of 'attempting to belittle the mining industry' and of being lacking when it came to a question of intelligence. These remarks have been made in different journals and represent the penalty one pays for taking the negative side in a popular belief. My chief crime seems to be that I have insisted that engineering rules which apply to individual mines should also apply when statements of 'fact' in regard to our national reserves are being made and when the life of these reserves is being estimated. No reputable Company, it is generally admitted, in developing its property will estimate its life mainly on probable reserves; it will not ignore loss in recovery and it will not, if it be a coal company, seriously consider seams 1 ft. thick at a depth of 1,000 feet. National reserves, I am convinced, should be treated in the same way." —(pp. 745-6 Can. Min. Jour. Nov. 3rd.)

I maintain that it is entirely illogical to compare and treat in the same way two things which are essentially different, such as the individual mine and the national resources in mining. These two things differ in this important essential affecting the point at issue; the individual mine has a restricted area, usually one, two or three claims—a matter of a hundred acres or so—whereas the national area is relatively almost infinite. The individual mine must find anything that is to benefit it on that restricted area or fail. The national resources have no such limitation. Furthermore it is a fact that by a collection of risks, risk can be eliminated. This elimination of risk can be complete or particular; for example, suppose an article worth one hundred dollars is sold at a raffle, 100 tickets being sold at one dollar each, then each person buying a ticket is gambling, which is defined as the "act of exchanging something small and certain for something large and uncertain." Now suppose one person buys all the tickets, then he has paid one hundred dollars, collected all the risks, and receives the article worth one hundred dollars. This transaction would not be gambling.

An Insurance Company, if it insured one man for $1,000,000, would indeed be gambling, and no Insurance Company would take such a risk without allotting part of it to other companies; but no Insurance Company would hesitate about taking risks on 1000 men for $1000 each. Life Insurance is perhaps the safest business known although it is based on taking risks on the most uncertain thing.

Now the individual mine is in a very similar position to a Life Insurance Company which has insured one man for a large amount and has taken no other risks, success or failure is all dependent on one thing, which is uncertain. Nationally there is no such condition, the failure of the individual mine is not ruinous to the nation. But with regard to mineral resources we are nationally somewhat in the position of the Life Insurance Company which has taken a large number of risks on the proper actuarial basis.

Let us consider Mr. Campbell's statement quoted above in another way and put it to the test. If it is correct and logical as a mode of thought now it was always correct. Supposing it had been necessary ten years ago or so to form an idea of the resources of the Cobalt district in silver. According to Mr. Campbell's argument one should simply take the estimates of ore reserves given by all the operating mines and add them together. And yet anyone following the course of development at that time and during the years preceding would know that in any given year the leading companies would issue a report showing that so many ounces, say 2 or 3 million, had been mined during the year, and so many ounces, possibly 5 or 6 million were estimated to be in reserve. The following year would show possibly more ounces in reserve than were estimated for the previous year, notwithstanding the fact that several million ounces had been taken out in the meantime thus showing that the estimated reserves were not in any way a true measure of the silver that existed on the property in question. Should that experience, occurring persistently, be ignored? Furthermore in such a calculation allowance should be made for the production of veins then undiscovered, but which proper observation and deduction would show would certainly be found. It is plain that an estimate made on Mr Campbell's principles above-mentioned would have been obviously ridiculous. Or again, about the same time that is ten years ago, would anyone who was required to make a survey of the mineral resources of Ontario have neglected to assign an important role to the gold mines? No gold mine was making a profit at that time and the ore reserves in the ordinary sense of the term were insignificant or non-existent, and yet it was obvious that gold mining was of importance for the future.

The Province of Ontario levies a tax on the profits of all mines. Does anyone maintain that this is now a provincial resource of substantial value and that a prudent company with ample means and well advised on the engineering standpoint would not pay a considerable amount for an assignment of the taxes if the province was willing and able to transfer the right to levy these taxes? If we followed Mr. Campbell's line of reasoning we could only assign a tax for one or two years. Provided the tax is unchanged, it is almost as certain as anything can be that ten or twenty years from now revenue under this tax will be [illegible] properties that are now unknown. At the present time the major part of the revenue under this tax is [illegible] from mines which were undiscovered [illegible] Act came into force fifteen years ago.

The illustrations used above are all taken from one [illegible] go. It is of course obvious that if the [illegible] argued holds true for the [illegible] mineral field, much more must it [illegible] national field.

G. R. Mickle

Toronto, Ontario.

*This letter is published concurrently in the Canadian Mining Journal and the Bulletin of the Canadian Institute of Mining and Metallurgy.

News and Comments

BY ALEXANDER GRAY

Babson A "Bull" On Canada

Not a word has got into the Canadian press about the remarks of Mr. Roger W. Babson, the Economist, at Cooper Institute, New York City. To an audience estimated at 10,000 (half as many more unable to gain access to the historic hall) Mr. Babson touched the metaphorical electric button when he declared that of all the places he knows of, from his study and personal information, Canada is the most attractive field for investment. Now, while Mr. Babson does not lay claim to being supernatural, or infallible in judgement, he is recognized as a super-economist, a student who correctly gauges the trend of affairs. Without being invidious or wishing to prejudice any field where capital can be safely employed, he gave precedence to the one country with a present under beneficent government, a statement, however, that did not imply misgivings as to the future of United States. The circumstances under which the utterance was staged and the applause it evoked, leaves no room for doubting the responsiveness of the audience, or the motives of the speaker. And what is more, he urged the location in Canada of branch manufacturing establishments. "Do it now," he declared in effect. "You may not profit for a while; but you should be prepared for what is certain to happen in Canada."

How the Figures Sermonize

The considerately compassionate Editor of *Canadian Mining Journal* has sought to "point a moral" that will be taken to heart by the well-meaning and the merely over-anxious who exceed the elastic limits of imagery in exaggerating surface showings. He delicately drew the hair-line between "half-truths," "white lies," if you will, and the downright prevarication which displays a patch as a blanket.

A prospect need not be compared with great producers. It need not be all its promoters would wish it, and yet contribute to the gold output. So the Editor advised the speedsters to get their machine "on low." Assuming some of the lapses from the verities to be "within the law" but infractions of the truth, he chided and benignly admonished them to "go and sin no more."

What was written in the last issue about "overstatements," consequently, was admirably catholic in spirit. Rather than classify as habituals those who subscribed to obviously misleading literature, the Editor indulged in dignified rebuke, leaving the anologous Ananiases who wheedle widows and orphans out of their slender hoardings, to be dealt with as the Law provides. He has no toleration to spare for those who contend that a "greater than Hollinger," "more propitious than Dome Mines," "more impressive than McIntyre," merely awaits a little canary seed to make it warble wealth.

As for the more incorrigible to whom the Editor addressed himself, it is unfortunate that those Analogists are confronted by Dome doings, how long it took to do them, and what it cost. McIntyre is a striking example of how a property could rise beyond its original sponsors, to become one of the three Porcupine pilots. How far removed are the tarradiddlers from a clear conception of the Hollinger past and present, is illustrated by the latest operating results, to November 11th.

To that date, in forty-five weeks, the Hollinger had milled 1,282,192 tons with a gross value of $10,977,982, making the weekly average spread over the period, $243,955. The weekly operating profit was $107.797, the total as given being $4,850,804.64. From the dividend standpoint, the profit was 75 per cent. in excess of requirements. The liquid surplus was over $7,000,000.

As the operating cost per ton milled was $4.4604, and the average value $8.56 per ton milled, the per ton profit was $4.10. This profit factor would have been higher were it not for the development policy in anticipation of the increased milling capacity. Notwithstanding this, the difference in cost favoraby compares with $5.2641 reported for the same period in 1921.

It is possible a shortage of power, and other causes, may increase costs and slightly curtail production during the final period. If these drawbacks do not seriously interfere, the mill will crush 1,500,000 tons in the year, for about $12,840,000, of which about $12,400,000 will be recovered.

Of the $10,977,982 representing the gross value of what was milled, $10,587,000, or thereabout, was recovered in the forty-five weeks. Of that, 45.8 per cent. was profit

All things considered, therefore, the company's operating profit this year may be around $5,750,000.

Such totals sustain the remonstrances of the Editor of the *Canadian Mining Journal*, rather than have the frequently ridiculous confounded with the sublime, when Dome Mines presage a production of about $4,500,000 and McIntyre may be relied upon to bring the combined production of Porcupine's trio nearly to $20,000,000.

Flaunting frills before there are more than furbelows cannot attract all the capital the North Country deserves, however bewitching the get-up.

TECK-HUGHES REPORT A MODEL ONE

The eighth annual report of the Teck Hughes Gold Mines of Kirkland Lake is excellent in its treatment of the affairs of the company and in the clarity and conciseness with which the General Superindendent D. L. H Forbes reviewed the operating mining and development position. Mr. Fobes did a very neat piece of work, stated the position so the shareholders can see for themselves. Without laboring obvious features he goes beyond his present estimated ore reserve—79,974 tons, gross value $1,183,176, averaging $14.79 per ton—and concludes:

> "On the whole, the year's operations were highly satisfactory and the finding of important ore-bodies in the No. 1 Vein at the 7th level is encouraging in relation to the future of the mine at greater depth."

Having put that of record, Mr. Forbes means it. He leaves the mine to harmonize his horoscope and current valuation of $1,183,176 with the company's capitalization of $3,870,000, plus $339,100; but the lower levels are so promising, the directorate is fortunate in having a General Superintendent to whom the property can be entrusted. To have done so well in a reconstruction period, when the mine demanded development under difficulties; in view of the fact that the crushing was not reached until May last, the financial year ending August 31st, the results are decidedly flattering to all concerned. In this connection the Directors have this to say

Sixth and Seventh Level Developments

"About the first of the year a better average grade of ore was obtained from the developments being made on the sixth level and January was unexpectedly good, and February fair. In March, April and May the tonnage treated was nearly to capacity of the mill but the grade of ore was not nearly as good as was expected owing principally to sloughing in a stope which caused a heavy dilution in the average grade going to the mill. In July the developments permitted ore from the sixth level to be again delivered to the mill and the grade treated that month averaged $23.14. In August the average heads were $23.55 and while it is not included in our fiscal year, it will be interesting to note that ore from the seventh level and from the new vein found to the north of the No. 3 vein at this level, added to ore from the levels above, brought the average grade treated up to $43.79 per ton. The Manager found that the high grade of ore being treated made it economically necessary to reduce the number of tons treated daily, and he has found that the treatment of about 100 tons per day is the best policy for this grade ore, and therefore, during September the average tonnage treated, owing to the high grade, was reduced to 88 tons per day, although the values of the ore treated that month was as high as $118,000."

On the altered running basis the September grade must have averaged very much higher than that of the ore reserves. Evidently Mr. Forbes hit the high spot and availed of it, which is permissible, considering the financial requirements. Of the new vein found on the seventh level to the north of the No. 3 Vein from which the bulk of the ore milled came, the Directors state that at the time of their writing it had been "drifted on for 440 feet. Two thirds of this length was in good ore and practically two thirds of the ore body encountered is high grade." No. 3 Vein also had been drifted on for "about 500 feet and two thirds of this length is in good ore and twothirds of the ore body is high grade ore."

For the first time, therefore, the company has a real current asset position — a liquidity of $254,993.99 as against current liabilities of approximately $34,100. There is an Impairment Debit of $366,251.35, after including the profit for the year amounting to $111,822.59.

Operating Details

It is in the lucid presentation of operating details that Mr. Forbes specially excelled, both in brevity and information. The 43,300 tons milled yielded $11.11 per ton. "Amounting to $481,111.02, the average being $11.11 per ton. "Including exchange premiums and interest, the gross revenue for the year was $50,407.63, or 11.58 per ton. The total *direct* operating cost was $306,912.53, or $7.09 per ton; while *indirect* charges, such as depreciation, new construction, financial charges, extraordinary expenses, etc., amounted to $82,672.51, or $1.91 per ton, making the total of direct and indirect charges come to $389,595.04 or $9, and leaving a net revenue of $111,822.59, or $2.58 per ton."

Candor and conservation of credits in this manner cultivate confidence, even though it may not enthuse speculators. Teck Hughes has had a thorny pathway. That the mine has retrieved itself as now shown, should have a bearing upon Kirkland Lake's producing section. Mr. Forbes is able to abandon his wonted reserve in his forward view, and development and drilling to further depths are in order. He supplements what the Directors said by giving this on the year's developments:

"On the 6th level, in addition to the expected ore shoots that were found in the No. 3 Vein, important ore bodies were discovered in two branch veins that strike northeasterly from No. 3 Vein; while, on the 7th level, running parallel to and north of the No. 3 Vein, the No. 4 vein was found to have high grade ore shoots of considerable length."

That may or may not explain the delphic utterance of the Directors, that "the Company has purchased and paid for some additional mining properties." It would have been more in line with the rest of this explicit annual report, if the purchases had been defined. Of the tonnage milled, 13 per cent. came from development. There is a broken ore reserve of 19,213 tons.

On the whole, the Teck Hughes and its Management are headed for the clearing. But conceding this does not suggest that the company is yet capable of continuous distribution of profits.

There is this to be further said of the Teck Hughes under the mangement of Mr. Forbes: The annual report is decidedly in the past tense. When the outputting returns for 1922 are tabulated, it will probably be found that Teck-Hughes is the second largest producer in the Kirkland Lake field, despite early milling grade and the fire and power failure from October 4 to November 4 — a whole month without milling. Teck Hughes performances are distinctive in their sphere, and it is the second deepest mine in the camp.

The following prospectus has appeared in the first (and last) issue of the "Unauthorized Bulletin of the C. I. M. & M.", published on the occasion of the recent Western Annual Meeting in Vancouver. This Bulletin is replete with information, mainly personal, and with suggestions for the progress of the Mining Industry, and is particularly strong on verse, again mainly personal. We regret we are promised "no more" issues of this delightful publication.

PROSPECTUS

COAST STEEL RANGE COMPANY

Officers:

Tickle Compson, Esq.	President
Kemal Pasha	Secretary

OBJECTS

The object of this Company is to [illegible] tonishing deposit of nickel-trimmed [illegible] discovered during the past summer by [illegible] celebrated iron expert of the Geolog[illegible] (o), B.C. In this vein, shoots [illegible] eription, are exposed [illegible] create greatly the felicity of [illegible] thermore vast opportunities [illegible] reason of negotiations [illegible] Turkish Government [illegible] ited output from [illegible] purpose of making [illegible] to hold.

The [illegible] to the following conditions:

1. [illegible]

2. The Turkish Government [illegible] dividends shall be paid to [illegible]

3. That the whole of the [illegible] [illegible] in Constantinople [illegible] Lemon.

The Company [illegible] Preferred shares [illegible] overcome the [illegible]

Iron Ore Smelting By Electricity

Alfred Stansfield, Birks professor of metallurgy at McGill University, Montreal, outlined some of the difficulties in the electric smelting of Canadian iron ores, in an address given Oct. 9, 1922, before the Cleveland Section of the Association of Iron and Steel Electrical Engineers. After tracing the history of the experiments at Sault Ste. Marie, Heroult (Calif.), and those in Sweden financed by the Jernkontoret, it became evident that the design of a successful furnace was no simple matter.

The "elektrometall" furnace, developed by the Swedes, was with some small exceptions the only one in successful commercial operation, but iron ores can be smelted successfully in the "Noble" furnace developed at Heroult and even in a plain, open-top, pit furnace, and these latter furnaces are preferable to the Swedish furnace for the production of gray foundry iron.

Gray Iron for Foundries

Whereas the Swedish furnace operates much like an ordinary iron blast furnace, in that ore reduction and even carbonization of the spongy iron is done by hot CO gas rushing up the stack, low furnaces, of course, must rely almost entirely upon direct contact with solid carbon for reduction and carburization. Doubt has been expressed that the latter will produce the gray iron required for ordinary foundry work in view of two facts: (1) The normal output of the Swedish "electro-metal" furnace is white iron, despite its approach to conventional blast-furnace principles; (2) that it was found exceedingly difficult to make "synthetic iron" containing more than 2½ per cent carbon, when remelting steel scrap with granular carbon in an electric furnace. Professor Stansfield was quite positive that these two facts had been stressed unduly. The Swedes make low-carbon white iron because that metal is more desirable for conversion into steel and wrought iron, and this is the use to which their production is put. Furthermore, synthetic pig iron carburizes so very slowly because the reaction takes place only at the surface of the bath, covered with floating carbon. Keller, in France, showed how to get high carbon by charging the carbon and steel scrap in layers. Therefore a pit furnace would produce high-carbon iron if there remained a slight excess of carbon in the ore column when it finally reached the bottom. This residue of coke or charcoal would rest on the hearth, supporting the granular charge above, and submerged in the molten metal, dissolving therein. Then if conditions were correct—the furnace operating with a "free-burning" arc at high voltage—silicon would also be reduced and the furnace would produce the soft graphite iron required for ordinary machinable castings.

Excess of Carbon in Charge is Fatal

An electric furnace is quite sensitive to correct proportioning of the charge. An excess of carbon arriving at the hearth will remain there, and even accumulate if some lean charges are not forthcoming, gradually plugging up the furnace and stopping the operations. It cannot be burned out with more air at the tuyeres, for there are no tuyeres. It simply remains until some solid oxide reacts with it or the metal dissolves it away. On the other hand, a cumulative slight deficiency in carbon (in an electric furnace) means poor reduction, large slag loss and a hard semi-steel, low in carbon and silicon. Even the best of electric smelting furnaces are subject to these troubles—a low pit furnace has something the better of the Swedish shaft furnace, in that a much shorter time is required for a corrective charge to work its way to the seat of the trouble.

Experience with several furnace designs indicates that iron is smelted best when the arc is free burning —i.e., immersed in the charge but slightly—and surrounded by an incandescent crater of flame and gas. Deep immersion diffuses the heat because many more paths through the ore charge are offered by which the current can leak from electrode to electrode. Short circuits are then frequent and the voltage must be reduced; partial fusion and reduction occurs at many points, and the charge has a tendency to "hang up." Even worse conditions result if the electrodes are forced still lower into the molten slag or metal, when the furnace becomes completely short circuited.

Economic Considerations

Professor Stansfield pointed out that inherently electric smelting demanded cheap power. Two-thirds of a ton of fuel per ton of pig iron may be saved, but in general the electric energy required (1 3 hp.-yr.) costs more than that much coke, although it may cost less than the amount of charcoal that would be saved. It follows that the electric furnace is unlikely to replace the coke blast furnace, though it has successfully replaced the charcoal blast furnace in Sweden. It was his opinion, also, that electrical energy was far too valuable a commodity to be used permanently in such a crude operation as ore smelting. It could be done only on the "outposts of civilization," where the power might easily be developed long before the demands of culture and industry could absorb it. As population increased, their multifarious needs would warrant them paying a far higher price for electricity, and ore smelting would be discontinued. This is not a particularly bright outlook for the method, however. The speaker said the reason, in his opinion, why electric pig iron was not now being produced in Canada was on account of their high labor and material costs and a lack of a special market which could be filled by that special quality of iron. But is it not true that labor and materials are always high in the outposts of civilization and there is never a local market for special irons and steels?

Professor Stansfield considered that there was a field for the application of electric smelting of iron ores on a limited scale at points where conditions were especially favorable, but that any large-scale development of electric smelting must form part of a process in which the ore would be reduced to the metallic state in fuel-fired furnaces at a low temperature before entering the electric melting furnace for the production of steel.—From Chemical and Metallurgical Engineering.

A booklet full of information for users of insulated conductors has just been issued by the Standard Underground Cable Company of Canada, and is available on request. Of particular interest to miners is the description of Standard Rubber Insulated Wire conductors, both twin and concentric, for mining machines.

CANADIAN ENGINEERING STANDARDS ASSOCIATION

The semi-annual meeting of the Main Committee of this Association was held November 13th, in Ottawa, at the Offices of the Association, Mr. H. H. Vaughan in the Chair.

After the transaction of formal business, the Secretary reported that the membership of the Association as of October 1st was 285, all members taking part in the work of various active committees of the Association.

Progress reports of the various working committees were presented, and it was announced that the Specifications for Steel Highway Bridges, Incandescent Lamps, Watthour Meters, Wood Poles for Transmission Lines, Flexible Wire Rope and Strand for Aircraft, and Commercial Bar Steel are well advanced or are ready for publication, that for Steel Highway Bridges being in the press. The Specification for Flexible Wire Rope and Strand for Aircraft was approved for publication.

In conformity with a request from the Secretary of State's Department, a formal resolution was passed changing the location of the Head Office of the Association from Montreal to Ottawa.

The Secretary's Report on the activities of the Association during the past six months was received and approved.

The personnel of a Sectional Committee on Road Materials and Construction under the Chairmanship of Mr. A. W. Campbell, Dominion Commissioner of Highways, was approved, this committee including representatives of all the Provincial highway authorities and, having as its principal object the obtaining of Dominion wide agreement on nomenclature, definitions and tests for road materials; and co-operating with the Committee recently appointed by the Engineering Institute of Canada on Road Construction.

A request having been received from the American Engineering Standards Committee for Co-operation in unifying divergent local requirements for the traffic Signals on Highways, it was decided to request the highway departments of the nine provincial governments, the Board of Railway Commissioners, the Canadian Automobile Association and other bodies interested in automobile traffic, the larger cities of the Dominion, the Engineering Institute of Canada, and the railway authorities to nominate members on this Committee. The functions of this Committee will be to make a survey of present conditions in Canada, prepare recommendations accordingly and consider these in connection with the draft suggestions to be prepared in the United States and forwarded by the American Engineering Standards Committee.

It was decided to take similar action in connection with a request for the Association's co-operation in connection with Specifications for Electric Overhead Crossings, the organizations interested in this case being the Board of Railway Commissioners, the steam and electric railway authorities, the power companies, and various power commissions, the provincial governments, and the various telegraph and telephone companies.

A suggestion from the Sub-Committee on Concrete and Reinforced Concrete that action should be taken looking to the preparation of specifications for Reinforced Concrete Poles was approved.

The Secretary reported that a number of favourable and some unfavourable replies had been received to the invitation sent out by the Honourable Mr. Robb, Minister of Trade and Commerce, for an interprovincial conference to be held under the auspices of the Association regarding the possibility of obtaining Dominion-wide agreement as to the requirements for the design, inspection and installation of electric fittings, appliances and equipment, and it was hoped that the conference in question would shortly be held.

It was announced that the grant to the Association from the Dominion Government has been continued for the fiscal year 1922-23, and other contributions to the funds of the Association were reported. The Auditor's Statement and balance sheet as of October 1st was received and approved.

A LITTLE TALK ON THRIFT

By S. W. STRAUS,
President American Society for Thrift

It is well to understand that the mere saving of money is not the sum total of thrift. This is a point that frequently is not given sufficient attention. Too often thrift is considered synonymous with tight-fistedness.

If it were true that thrift consisted merely of a narrow-minded process of hoarding, this country would never have attained its present exalted place because most of our national leaders have been successful primarily through thrift.

Thrift is no more the manifestation of selfishness and small mindedness than is success itself. Thrift does away with waste. It is careful planning and wise spending. It is efficiency and progress. Washington once advised a friend that "it is not the lowest priced goods that are always the cheapest." And in this advice he reflected one of the great truths of thrift. Spend money savingly. Save money sensibly.

We have had too much one-sided teaching on this subject. Too much emphasis has been placed on the word "Save" and not enough on the word "Thrift" in its broad, progressive sense.

Let us understand more fully that it is essential to save with prudence. It is also just as necessary from the standpoint of progress that we learn how to spend wisely, and achieve success through the exercise of good judgment and rightful transactions.

It would not be possible to exaggerate the simple virtue of saving. Since the days of human progress, it has been one of the most necessary of all personal practices. Every encouragement should be given to those who are saving. Encouragement should not stop there. It is sometimes the better part of thrift to spend a dollar sometimes if occasion warrants to purchase an article for $10 that [illegible]. The right kind of spending keeps business going, creates demand for labor, builds up our cities and [illegible] incentive and reward for enterprise and prudence.

Unless we understand and practice [illegible] we do not comprehend thrift.

The Orpaulic Lagoon at Leopoldville [illegible] tent, under which it is hoped to [illegible] pool, bacteria drained by the Bureau [illegible]. The land is now available for [illegible] oil has been commenced.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Coniagas takes over Beaver.— Several deals for ground in Cobalt and the vicinity have recently been concluded by different Cobalt companies. The deal between the Coniagas and the Beaver has been completed and it is understood that work on the Beaver will be started very shortly. The Beaver had a working agreement on the Badger and Prince properties and development of these properties will also be undertaken by the Coniagas. The Beaver mill will be enlarged to a capacity of 150 tons a day to permit of the treatment of lower grade ores, but the chief work will be the development of the lower contact. The Beaver has a shaft down 1400 feet and at this depth a strong vein carrying some silver pockets was found. On account of an extensive roll which is known to occur in the diabase, it is believed that this vein offers excellent possibilities. The basis on which these properties are being taken over is not known definitely, but it is understood to be on a profit sharing arrangement.

Continental takes over Silver Cliff.— The Continental Mines has taken over the Silver Cliff. It is not believed that any immediate work will be undertaken on the Silver Cliff, but is was considered advisable to take the property over in case the Colonial veins went that far.

Mining Corporation takes over Little Keeley.— The Mining Corporation has aequired the Little Keeley property in South Lorrain and as is also understood to have taken a lease on the Peterson Lake property in Cobalt. September production of the Mining Corporation was 173,290 ounces from 8,051 tons of ore, which should show a snbstantial profit. While September has been the best month, production for the year will run about 1,500,000 ounces.

No Assignment of Bailey.— Bailey officials state that the company has not assigned to the Toronto General Trusts as was reported.

Victory Silver Closed.— Work has been stopped on the property of the Victory Silver Mine.

Colonial.— The Colonial shaft has reached a depth of 450 feet. It is being sunk to a depth of 900 feet.

Keeley Record.— During the month of October the Keeley produced 93,540 ounces, which constitutes a record to date. Production for the first ten months of the year has been 606,000 ounces. The property is in excellent shape and engineers state that they never saw a better showing in any of the Cobalt mines.

Cobalt Shipment.— During the week ending Nov. 17th, the Mining Corporation was the only shipper from Cobalt, with three cars containing 226,000 lbs.

Mill Closed.— The Dominion Reduction has closed down for the winter.

Kirkland.— Aetivity in Kirkland continues and general conditions throughout the district are decidedly encouraging. The Kirkland Gold is now making a profit and is finding good ore on the 1000-foot level. The Sylvanite with a shaft down to 500 feet is making preparations to sink to 800 feet. Developments recently at the Teck-Hughes have been very favorable and mill heads have been running over $40.00 a ton. Two shifts are being worked at the Goodfish and drifting is being done on the 200-foot level. The Continental has found several encouraging showings and is considering the sinking of a shaft.

Walsh Claims Optioned.— A deal has been concluded for the Walsh claims in Catharine township, ten miles north of Englehart, the option being taken for English interests represented by A. D. Miles. Further surface work will be done preparatory to diamond-drilling. These same interests are diamond-drilling the Skead Gold mines and the first hole is understsood to have intercepted a vein carrying encouraging gold values.

Patricia Prospect.— Philadelphia people are investigating the Patricia property with a view to reopening it.

Goldale.— An encouraging find has been made on the 500-foot level of the Goldale where one of the crossents cut twelve feet of $8.00 ore. The property is well located and is being energetically developed.

Davidson.— Davidson Consolidated shareholders have been asked to ratify a by-law providing for the distribution of 400,000 preferred and 1,000,000 ordinary shares of the Porcupine Davidson, which are owned by the Davidstn Consolidated. They were also asked to ratify the sale of 268,105 preferred and 638,411 ordinary shares of Porcupine Davidson. The latter company is an English company capitalized at $1,000,000 which bought the Davidson property for a share consideration. Shares were offered in England but the issue was not well received and in order to provide funds for development the English interests are buying back shares from the Davidson Consolidated on the understanding that the money will be loaned for two years in order to build a mill and sink a shaft. The company is also considering the purchase of adjoining properties.

Steam Power Plant.— The Consolidated West Dome Lake will instal a steam plant in order to carry on work during the power shortage.

More Power.— The Great Northern Power Company, which is installing a hydro electric plant on the Montreal River above Elk Lake, is putting out a bond issue of $850,000 to provide funds for extensions to the plant. The Indian Chutes plant can develop 6500 horse-power.

A plant is in course of erection at a peat bog near Eaton Rapids, Michigan, for the production of peat fuel at the rate of 100 tons of prepared fuel per day.

It is stated by engineers conversant with the ore-deposits and coal seams of the Belgian Congo that that part of mid-continental Africa will soon be one of the world's important metallurgical centers.

BRITISH COLUMBIA

A New Machine.—Alexander Halliday, of Prince Rupert, claims to have designed a plant which, within itself, combines the functions of crusher, gravity concentrator, and oil flotation. As it can be built to any scale, and as the smaller types are easily transported, the inventor thinks that he has hit on something that will appeal strongly to the prospector and small operator in this Province.

Gold Mine Reverts to Owners.—The Bullion Mine, famous by reason of its gold production when operated by the late J. B. Hobbson and because of subsequent litigation in connection with the title to the property, once more has been before the Courts. A syndicate represented by Max Macgowan, of Vancouver, took it over some months ago, the intention being to raise sufficient funds to resume operations on a large scale. Mr. Macgowan's plans, however, appear to have failed and an order now has been granted under which the property reverts to the former owners, W. T. Ward and associates.

Trail Ore Shipments.—Shipments to the Trail Smelter, Canadian Consolidated Mining & Smelting Co., during the week November 8 to 14, aggregated 8,576 tons. There were four new shippers, the Gem, 12 tons; the Noonday, 26 tons; the Ore Bin, 2 tons, all of Sandon; while the Silver Dollar, with 28 tons, is situated near Salmo, in the Nelson-Arrow Lakes division. Other shippers were: Alamo, Alamo, 46; Bell, Beaverdell, 37; Knob Hill, Republic, 54; Molly Hughes, N. Denver, 5; Quilp, Republic, 101; Rambler, Cariboo, 106; Silversmith, Sandon, 138; Standard, Silverton, 180; Van Roi, Silverton, 46; Whitewater, Retallack, 27; and company mines, 7765.

Ore Testing Plant.—No decision has yet been reached as to the location of the ore testing plant the Dominion Government proposes establishing in British Columbia. Dr. J. H. King, Minister of Public Works, Ottawa, assures his constituents of the City of Cranbrook, East Kootenay, that he is "hopeful" that $100,000 will be placed in estimates at the next Session as a result of a "full investigation by Mines Department this summer." The Minister adds: "the location of the plant must be left to the judgment of officials, with a view to having a location so the mining industry can be best served."

Gold and Silver in Cassiar.—James Lapscombe, agent for the White Pass & Yukon Railway Company at Atlin, B. C., says that the placer mining production for the Cassiar district for the past season will be about the same as last year, viz., $111,200. Near the town of Atlin a silver lead property is being developed by J. M. Ruffner, the results of which it would be premature to forecast. The ore-bodies are promising and Mr. Ruffner is looking forward with confidence to receiving good reports on a small trial shipment of ore shipped recently.

Optimistic View of Cedar Creek.—E. J. Bourne, a mining engineer well known in the Cobalt district, Ont., has been inspecting the Cedar Creek placer field, Cariboo. He takes a fairly optimistic view of conditions there. Lower operating and material costs of course would be a great help to those interested in its development, he states. He expressed the opinion that the British Columbia legislature should be careful not to over-tax the mining industry. The treatment of mines generously in this respect would be rewarded by increased activity.

Alexander Estate Retains Engineer Mine.—The Engineer Mine, Atlin, B. C., reputed to be the richest lode gold mining property in the Province, belongs to the heirs of Allan I. Smith, of Philadelphia. Judgment has been given by the Privy Council to this effect. The group of claims known as "The Engineer Mine" are situated on the shores of Taku Arm of Lake Tagish and were first staked in 1899. In the followed year it was acquired by the Engineer Mining Company, an American corporation, and during the ensuing five years considerable exploration work was done. The necessary assessment work was not recorded in 1907, nor was the Corporation's Free Miner's Certificate renewed. This resulted in the lapsing of the title and the late Captain James Alexander re-staked in 1907 and spent considerable sums in development and in mine equipment, ultimately obtaining Crown Grants to the property. In 1918 Captain Alexander and his wife were drowned. A will was located in Montreal under which Allan I. Smith was made his heir. The mine was in the hands of the official administrator when matters were further complicated by Mr. Smith's sudden death. The rights of his heirs were attacked by the Engineer Mining Company on the ground that the claims had been "jumped", and for other cause duly set out. It appears, however, that the maze of legal entanglement now has been cleared away, that Mr. Smith's estate is confirmed in its possession, and that something can be done now in the way of operation. This summer, it is authentically reported, representatives of strong mining interests have been thoroughly inspecting and reporting upon "The Engineer." If their reports are favorable early news may be expected of the transfer of the property and of plans to re-open and place it on a shipping basis.

Iron and Steel Industry.—The British Columbia Government states that negotiations for the establishment of an iron and steel industry in the Province have not advanced very far. The Minister of Mines in the House recently declared that no assistance would be given without full information first being laid before the Legislature and that the policy was to encourage such concerns as were ready to furnish strong financial backing and possessed practical experience in iron and steel manufacture acquired either in Europe or America.

NOVA SCOTIA

Submarine Coal Mining.—The paper on submarine coal mining read recently by Mr. F. W. Gray before a meeting of the Engineering Institute of Canada at Sydney was intended to stimulate discussion on this topic, which is of prime importance in Nova Scotian coal fields. It has succeeded in its object. Mr. Gray's conclusion that in the case of the Mabou mine "the flooding was due to poor management" has aroused some discussion. It is hoped yet to recover the mine. The flooding of the Port Hood mine, stated Mr. Gray, has never been satisfactorily explained. The strata along the shores of Glace Bay, New Waterford and Sydney Mines are regular and without fractures and mining men may rest assured of adequate protection from the sea, though at any time unknown geological conditions may be encountered as the mines advance.

Mine Fire at Inverness.—The fire in Inverness Mine is still burning, and has so far defied all attempts to put it out. It is now being walled off. It broke out in a chute at No. 7 landing, and filled the mine with smoke and black damp. Rescue corps from Stellarton and from the Dominion Collieries went to the help of the Inverness men, taking with them their smoke helmets and other fire fighting equipment. It was found

impossible, however, to use these owing to the height of the seam. A crush had taken place in this district, and the seam was only about two feet high, and so much stone had been piled on the sides of the chute that there was just about 2 feet space to work in. It took a considerable time to clear out the black damp and get down to No. 7 chute where the fire had started. It was found impossible, however, to get up close to the fire owing to the crush that had taken place, as stoppings built could not be made tight, and air was carried up with the men. A temporary stopping was built below this chute and an effort made to go on to No. 8 chute, which was further in. This was slow work, but was finally accomplished. Stoppings were built the whole length of this chute, but here again progress was necessarily slow owing to the fact that the crushed walls caused leakage when the stoppings were put up. It is the intention to go in from the upper part of No. 8 chute and wall off the top of No. 7 chute. With permanent concrete stoppings above and below the burning area, the fire may be damped out. Work is being carried on as usual in the other parts of the mine.

On the same day that the Canadian Newspapers informed the public of Lenine's proclaimation favoring a return to capitalism the United Mine Workers of Nova Scotia at a sub-convention decided against uniting with the Third International of Moscow. The action of the convention is merely a coincidence and is not to be taken as a change of front on the part of the Red leaders, whose faces are still set towards their comrades of the Revolution. The truth is, Nova Scotia miners never favored Moscow, although some of them permitted themselves to be used to elect Red officials to position. This object attained, the Moscow program was dropped and a new one, or rather a borrowed one, the six-hour day and five-day week, was taken up. It may be new to Nova Scotia but it has been discarded in Britain, and is likely to be thrown aside, in the United States when the report of the commission that is now investigating mining conditions in that country is handed down. There is no necessity for a six-hour day and a five-day week, in the mines of Nova Scotia. There is no over-production, and there never was any, nor is there likely to be for many years to come.

India is becoming rapidly an important factor in the iron and steel trade of the East. Japanese manufacturers are now feeling the effect of India's competition in Japan.

During September 5203 tons of pig-iron was exported from the United States. Of this over half, or 3768 tons, came to Ontario and Quebec.

The report of "strikes" of copper ore in the Bird Lake area, 70 miles northeast of Winnipeg has started a rush, and a large area has been staked. It is reported that exploration with the diamond drill is to be conducted during the winter.

The Transvaal gold output for October 1922 amounted to 778,159 fine ounces, as compared with 747,089 fine ounces for September 1922, and 707,825 fine ounces for October 1921. The figures for last month show that the Rand has beaten all records since October 1916, and exceeds the corresponding output for the same month in 1921 by 70,000 ounces. This result is to be attributed entirely to improved efficiency in rock-breaking and a better working tone among the natives.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers, whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers:—One-eigthpage, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings.

Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invited to write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

EDITORIAL

Is quite evident that one of the purposes which the [Canadian Mining] Institute places before itself is the checking of "booming" and artificial inflation in relation to mining speculation, and more particularly the prevention, so far as possible of fraudulent or misleading prospectuses—Lord Aberdeen—1897.

HOW DID THE GOLD DEPOSITS ORIGINATE?

In these modern times there has grown up round every large mining camp a mass of geological lore and theories, which usually is boiled down after a time to a few well-founded ideas that prove extremely useful in the exploitation of the camp's resources. It is expressly a search for these ideas that has occupied Mr. Cyril W. Knight of the Ontario Department of Mines in the Cobalt silver field for the last two years. The result in this case has justified fully his search.

In the case of the Porcupine gold camp, there has not been the amount of public discussion among geologists and miners about the origin of the ore-bodies that usually attends the development of a camp of its dimensions. This may be due to there being so few producing mines, the students of conditions in each of these few having kept his conclusions as private property. This exclusiveness is not in the best interests of the camp as a whole. There should be more public discussion of Porcupine's economic geology. An excellent foundation has been laid for such a discussion in the reports of the Ontario Department of Mines; but Porcupine's miners and geologists have failed to build upon it. In this connection, the present studies of Mr. A. G. Burrows are awaited with the greatest interest. There is a rumour that he is going to throw a large sized bomb into the camp, whose bursting fragments will bowl over many a sedate, and possibly unsuspecting, theorist.

Meantime we are able to present today a timely geological argument and deduction. Mr. Murray's article based on the field work of Mr. Clifford Smith, certainly will not meet with unanimous approval throughout the Porcupine camp, if it did, part of its object would be frustrated. It presents a simple explanation of the occurrence of workable deposits of gold on one property that may be applicable, in whole or in part, to other properties. If the deductions are correct, it will prove a valuable aid in further exploration.

We hope that Mr. Murray's article will initiate a profitable and wide-spread public discussion of the origin of the gold deposits of Porcupine and other northern camps.

PROTECTION AGAINST FRAUD

It is indeed encouraging to find that at last a conference, under official auspices, has been called to consider the question of more efficient protection of the investor in mining shares in the Dominion's principal mining province. On several occasions lately public officials have made a genuine attempt to curb the activities of "wild-cat" gold mine promoters in Toronto and elsewhere throughout the province. Uniformly they have found that the wily gentry of the slippery kind who were responsible for the nefarious trade had already found a loop-hole in the laws through which to retreat to safety. This is, of course, characteristic of the light fingered profession in general.

Already a great deal of money has been thus collected, and consequently lost to the genuine mining industry. Some well-directed publicity during the last few weeks has, no doubt, alleviated the case considerably; but still there are a number of purveyors of worthless mining script at work in Ontario, as elsewhere. There is now a genuine body of public sentiment behind the movement to make this type of thievery illegal. This will give heart to those both private individuals and public officials, who have been trying for years to develop some rational means of protecting those investors who are susceptible to protection.

A number of recent events point to the conclusion that protective legislation of a moderate and rational sort, designed principally to prevent the incorporation of companies intended obviously as a means to barefaced robbery, will not by any means impede the development of mining prospects worth developing; it will, on the contrary, stimulate honest and rational mining development. Lately a number of mining promoters destitute of funds with which to develop their prospects have stated their case honestly and plainly, and have met with a ready response from investors. This is in spite of the fact regarding the speculative mining stock now enjoying such unmerited reserve. If the investing public [illegible] a reasonable degree of protection from fraud there is no doubt there would be a very large amount of capital

capital available for mining development, principally from small investors, — much more than the amount now being dissipated annually by the sale of bogus stock.

The discussion on "Blue Sky" legislation at the meeting of the Canadian Institute of Mining and Metallurgy last month illustrates another point at issue. Last winter, and previously, a flood of useless gold mining script based upon supposed mines in Northern Manitoba was poured into Montreal. The promoters could not satisfy the protective laws of Manitoba, so sought victims in Quebec, where there are no such laws. There were many victims. Not one of these properties is now a productive gold mine, and it is unlikely that any of them will ever return a dollar to the shareholders. An analogous case was the sale in Montreal recently of certain Ontario gold mining stocks that could not be sold legally in Ontario. The *Canadian Mining Journal* investigated one such case of bare-faced fraud and found that the Ontario provincial authorities, though willing and anxious to bring the culprits to justice, were unable to take any action, because, though the fake company was represented as incorporated in the province of Ontario, the fraud was being committed in the province of Quebec. There must be some measure of uniformity and of co-operation among the various provinces if the laws are to be effective.

Most of the provinces have now reasonable and effective "Blue Sky" legislation. If Ontario is added to the number, there is no doubt that soon there will be a Dominion-wide protection against stock-jobbers. If the laws for Ontario are formulated in the moderate and rational spirit that seems to pervade the present conference in Toronto, we are confident that our mining industry will benefit materially.

CANADA'S MINERAL RESOURCES, ONCE MORE

The cautious Westerner has raised a storm of protest among his fellow-engineers in the notoriously conservative East. Today we print still another reply to Mr. Campbell's letter in the *Journal* of November 3rd, in which Dr. Corless vindicates his original statements and points out some discrepancies in Mr. Campbell's deductions.

If this question of the potential capacity and relative importance of Canada's mineral resources concerned a topic of minor importance only, the volume of discussion that has centred round it would have become wearisome long ago. The fact is that it is a question of vital importance to Canada and to all Canadians, and any discussion that can aid in its clearer comprehension and that can point the way to progress is well worth while. The whole of the discussion so far has been profitable.

While we cannot agree with Mr. Campbell in his general conclusions, we appreciate the value of a good deal of the material he has brought forward to support his argument. Particularly do we value the service he has done in opposing, single-handed, the hosts of optimism. Optimists (*we* optimists) need a periodical corrective to our ruling tendency, lest caution be thrown to the winds. Mr. Campbell has earned the thanks of his brother engineers for having set himself to a task that few would be willing to undertake, and that would be shirked by any but a man of his determination and public spirit.

CANADIAN COPPER FOR CANADA

A news despatch from British Columbia states: "Although this province produced the bulk of copper mined in Canada, British Columbia has only three small plants manufacturing brass and copper articles, with an annual production of $57,314, as compared with 59 manufacturing plants in Canada, with an annual production value of $13,760,311. The bulk of the manufacturing plants are in Ontario and Quebec. Ontario has 39 plants, producing $6,774,066 worth of goods; Manitoba three, producing $955,998; Quebec twelve, producing $5,525,153; and New Brunswick two, producing $477,780."

It has been pointed out on numerous occasions that although Canada produces almost, if not quite, sufficient copper to meet her own needs, most of it is exported in the raw form and imported again as manufactured materials or as a raw product for our factories. Stated thus badly one is liable to draw a wrong conclusion. The statement ignores the segregation of our producers of copper in the extreme west and of our principal manufactories in the east. If the Rocky Mountains were less of a barrier to freight traffic than they are, the apparent anomoly of our exports and imports of copper would be less striking.

It is certain, however, that this unsatisfactory export of our copper and the importing of its equivalent from mines in the western United States only a few hundred miles less distant can be lessened by means of a determined and systematic effort, particularly if there were effective and continuous co-operation between the producers in the west and the consumers in the east. It is to the solution of problems such as this that the efforts of the Trade Associations now in vogue in Great Britain have been applied with such signal success. The vast majority of our specific trades including the copper and brass trade, still lack the aid of this most effective expedient. Also, the natural geographical division of our country into East and West, overcome in the first instance by the superb efforts of those that built the Canadian Pacific Railway, still effects us adversely, and to some degree unnecessarily. We are confident that if Canada's cop

per trade can develop an advocate with qualities approaching those of the men who built our first transcontinental railway, our own copper will find a much more extended use within our own borders.

AN EMPIRE COUNCIL OF MINING ENGINEERS

In these days the bonds of Empire are being forged with a rapidity that would startle most of us if we could realize it fully. In the pre-war times the bonds that united the scattered bits of British red that dot the globe were largely the rather intangible feelings of consanguinity, racial sympathy and sentiment, with a more tangible manifestation in trade and in material interests common to all. Since 1914 we have had many clear-cut evidences of the fact that the Empire is one and indivisible. A fresh item of evidence is recorded in our pages today.

We wish to draw attention to the report, in Mr. Roland H. Briggs' account of the recent annual meeting of the Institution of Mining Engineers in London, of the official proposal to form an Empire Council of Mining and Metallurgical Engineering. This is a move of decided importance to the mining engineers of the Empire's component parts, as well as to the Empire as a whole.

There is being developed rapidly, by various means, an inter-Imperial interest in mining affairs that promises much good for the Empire. Chief among the agencies at work is the Imperial Mineral Resources Bureau whose activities and reports have had some notice in these pages. The personal contact and personal interest that would be fostered by the proposed Empire Council of Mining and Metallurgical Engineering would go far toward supplementing the good work already being done to consolidate the interests of the mining engineers of all the British dominion, for the ultimate benefit of all.

EDITORIAL NOTES

Today we quote, at the top of these pages, a sentence from a speech of the Governor-General, Lord Aberdeen, to the Canadian Mining Institute twenty-five years ago. The tone of this sentence pervaded his whole speech. It is evident that the members of the Institute of that day, when the gold boom of Northwestern Ontario was rising to its height, realized its folly and were actively concerned to prevent the dissipation of capital they saw going on. We wonder if the shade of Lord Aberdeen visiting the 1923 meeting of the Institute, will find its members equally jealous of their profession's good name. We hope so.

The verse "Prolepsis" in our issue of November 10th, addressed to the C. I. M. & M. meeting in Vancouver, has inspired a Gallic bard on the Pacific, as evidence below. It is no breach of confidence to say that he acquired the art of producing these rolling cadences on the Atlantic side, where a profound study of the Greek language is apparently still in vogue.

The trade returns for Canada for the twelve months ending October, 1922, include the following items:

Imports	
Iron and its Products	$120,901,813
Non-Ferrous Metal Products	33,649,163
Non-Metallic Mineral Products	116,654,048
Exports	
Iron and its Products	$38,087,096
Non-Ferrous Metal Products	34,747,516
Non-Metallic Mineral Products	23,058,672

These figures may well provide food for thought for all Canadians, and particularly for the mining engineers and metallurgists of Canada, upon whose initiative and resource our country must depend mainly to stop this annual drain upon income.

The Fourth Annual General Western Meeting of the Canadian Institute of Mining and Metallurgy — 1922

EPANALEPSIS

From where Atlantic roars with sullen surge,
There came Odell, sent hither by the urge
Of travel. On his train he brought
Leaders in the domain of mining thought
Camsell and Wallace; Allan; Whiteside too,
And Burrows, Shanks and Richards, all to do
Their utmost at Vancouver to make clear
The value of these meetings once a year.
McLeish and Haanel came and many more
Representation right from shore to shore
As was predicted, Wilson too was here,
Philosophizing in his way sincere
On many things. And two at least
By watches know his bounty at the feast.
Not only from our eastern marches wide
Did members come, but also from outside
Our land, Rickard laid down the laws
Of journalism amid much applause;
And L. K. Armstrong with his silver tongue
Described the peaceful boundary so far flung
But one was absent. One we did not see
Stalking the corridors. And fain would we
Have had him in our midst—cloud piercing Spike—
If only at his polleies to strike!

* * *

'Tis over. This Fourth Meeting in the west
Undoubtedly has been the very best
Of all yet held. And from Vancouver's isle
To far Cape Breton here convened the while
Men who brought freely to the Council board
Their store of knowledge, and disdained to hoard
It from their fellows. May the fashion be
Always thus in our mining industry!

CABER FEIDH

The Shear Zones of Porcupine

WITH SPECIAL REFERENCE TO THE ANKERITE MINE

By J. C. MURRAY

The object of this article is to correlate certain geological facts, some of which have not yet, so far as the writer is aware, been assigned their rightful places in the written history of the gold deposits of Porcupine, Ontario. The article is based in great part upon the records of work privately carried on. Acknowledgement of this is made hereunder. It is also the writer's wish to express unequivocally his indebtedness to the publications of the Ontario Department of Mines. Without these necessary guides the geology of Porcupine would still be an unopened book.

* * *

Space does not permit the full setting forth of the writer's premises. A seemingly dogmatic tone is, therefore, to be overlooked as being unavoidable.

Introductory

In the first days of Porcupine the prospector looked for quartz. Quartz veins were veins, and therefore to be staked, no matter what their surroundings nor how uncompromisingly "tight" the rock in which they were found.

Very early it was found that veins in the vicinity of porphyry contacts showed better values than did those not so situated. Almost contemporaneously it was noted that, in the zones of schisting induced by porphyry intrusions, the silicified schists were more or less impregnated with sulphides and sometimes gave interesting assay results. This directed attention to the schists themselves, rather than to the true ore bodies within them, and encouraged exploration along zones of such schists. Schist was looked upon as ore *per se*. The outcome was disappointment.

This and other illusions have not yet been entirely dispelled, although later experience has proved that, where these schists *are* ore, they are only incidentally so because of distinctly traceable influences. Putting it another way, the schists have shared incidentally the enrichment of the true ore bodies.

The Process of Ore-Making

The original silicification of the schists, manifested in the networks of quartz veinlets, was but one step in the general enrichment, or, rather, in the processes preceding enrichment. It is not yet generally recognized that shearing and structural deformation within the zones of schisting were pre-essentials of ore-making. That these were essential factors has been proved abundantly within the last year or two by underground development at the most important mines. The first systematic demonstration, however, was afforded by the exploratory work planned and carried out at the Ankerite mine.

Where intrusive porphyry has brought about only schisting and silicification, the one later, but prime, factor is missing. Schist may, and does, carry gold over wide areas, in non-commercial quantities, but so also do other metamorphic rocks. The missing factor is supplied when, in addition to schisting, shearing and deformation also have occurred.

In such cases the schisted zones have been fractured, usually, as at the Ankerite, at a low angle to both the strike and the dip of the schist. Following this, the fractures were filled by the agency of highly siliceous, enriched solutions of deep-seated origin.

Local enrichment (the formation of ore-shoots) resulted from structural deformation of the already fissured schist. Intense folding and faulting of the schist, and dislocation by masses of intruding porphyry and lateral thrusts, afforder the stoppages, or "dams," which, by obstructing the flow of the ore-bearing solutions through the fissures, made possible the local enrichments that constitute Porcupine's important ore bodies.

Enrichment at the Ankerite follows observably the folding and faulting traceable on the surface.

Differentiation of Vein Matter and Schist

That there is a fundamental difference between the quartz deposition in the veins and the earlier silicification of the schist, is apparent on inspection. The well-marked vein walls are characterized by an abrupt change from sericitized to unsericitized rock, and by more or less lamination of the wall rock. Moreover, the higher and more consistent gold content of the vein filling as compared with the silicified schist, the marked difference in the appearance of the sulphides, and the presence of tourmaline in the vein filling, distinguish it sharply from the surrounding schist.

There is much evidence to show that the vein filling is of later date than, and of origin entirely different from, the silicification of the schist. In the opinion of the writer the silicification of the schist was essentially local, a phase of contact metamorphism, resulting wholly from the first intrusive action of the porphyry. The vein filling, on the other hand, was a concomitant of the later shearing, and involved the release of pregnant solutions of profound origin, under great pressures and at high temperatures.

An extract from a paper on the ore deposits of Butte, Montana, is appropriate here : "It is a reasonable assump-"tion that the quartz-prophyry was derived primarily from "the parent granite magma; and also that the ultimate "source of the ore minerals was the granite magma. The "principal part played by the quartz-porphyry has appar-"ently been the preparation of the way for vein-forming "waters of deep-seated origin to reach the regions where "the ore deposits are now found.

"While the ultimate source of the metals was probably the "original granite magma, the direct source may have been "the same magma locally which furnished the quartz-por-"phyry, the latter rock following the earliest fracturing "and at the same time stimulating an upward movement of "the ore-bearing waters."* In passing it may be pointed out that the close association of ore and porphyry in the Porcupine region does not necessarily imply that the latter is the original source of the ore.

The pronounced difference in the appearance of the pyrite that is found in the silicified schist and that found in the vein filling is significant of the different origin. The sulphide found in the schist is sprinkled irregularly in distinct cubic crystals. The granular pyrite that characterizes the ore bodies is micro-crystalline, lighter in colour than the former, and much more plentiful. It (the vein pyrite) is grouped in fine-grained bunches, and not thinly sprinkled as is the pyrite in the schist. Moreover, the pyrite in the schist is low in gold content, while the vein py

*"Ore Deposits at Butte, Mont.," by Reno Sales, Trans. A. I. M. E., Vol. XLVI

rite, along with tourmaline, is always associated with high gold content in the ore.

No tourmaline has been found in the schist, but it is plentiful in the vein filling. The occurrence of tourmaline in the vein filling has all the significance that the practical prospector used to attach to the word "indicator." The dark coloration of a great deal of the vein quartz was found, on examination under the microscope at McGill University, to consist of fine needles of tourmaline. Visible crystals of the mineral are found occasionally but not frequently.

Structure and Vein System

The writer has been permitted to make use of a private report* that presents clearly the facts on which the above statements are based, and that embodies the results of the first work done in the Porcupine camp guided by a knowledge of local structural relationships. The work done at the Ankerite specifically determined these relationships and threw light upon the nature and causes of local enrichment. The essential role played by structural deformation was evident early in the progress of surface exploration.

The conditions encountered at the Ankerite on the surface were duplicated underground at the Dome and McIntyre. At the Ankerite the surface work rendered the structural geology diagrammatic in its simplicity. Underground, at the other mines, interpretation came more slowly. At the McIntyre, for instance, a number of veins have been cut in the sheared schist which underlies the body of porphyry pitching into the former property at depth from Hollinger ground. The discovery of these veins was the result (and the reward) of bold and reasoned underground prospecting. It revealed conditions strictly analogous to those demonstrated on the surface at the Ankerite. In the case of these McIntyre veins it is recognized that the intruding porphyry has acted as a "dam" in localizing gold deposition.

At this point it is appropriate to quote from the private report referred to above: "It appears probable, from both the local and the broader features of the field, that there has been a profound faulting of the country for miles in a general N. E. S. W. line, with local lateral thrusts at approximate right angles to the general direction of shearing. Spurs of fissuring and faulting also extend as subsidiaries from the general line. But the main movement, with its lateral thrusts which tend to give it something of a zig-zag course, has been the chief conditioning factor. The Dome, West Dome, and Ankerite mines, and other known deposits, lie in the main line of movement, both the Dome and the Ankerite deposits lying in zig-zags, or elbows, of the cross-country faulting."

One feature of the metamorphism of the schists that has been much misunderstood is discussed in the report in question, and emphasis is laid upon a point that has long needed attention. "I wish to call especial attention to the nature of the so-called 'ankerite dykes,' because of the general looseness and confusion of ideas concerning them.

"High carbonate content is a feature of practically all altered rocks of the Porcupine area, and practically all rocks of the Porcupine area are thus altered, the degree of alteration corresponding closely to the intensity of structural changes. In some localities the carbonate schists carry considerable iron carbonate and iron sulphide and weather to a rusty appearance, which has given rise to the misnomer 'ankerite dykes.' Although these carbonate schists often contain stringers of quartz that may be rich in gold, they offer no possibility of profitable mining."

*Report of Clifford E. C. Smith on the Ankerite Gold Mines, Porcupine, Ont., 1918.

The supposition that these rusty schists were the object of attention at the Ankerite gave rise to misapprehension as to the real purpose of the work done there. The intensive geological investigation conducted on that property proved conclusively that the highly mineralized fillings of the shear fissures constitute the payable ore bodies, and that these occur in the form of parrallel and continuous veins in two distinct zones.

To proceed, the report touches thus upon the vein systems: "The pofitable gold deposition of the Ankerite property lies in strong veins which cut the rusty carbonate schists and the several other rock phases, including the intrusive porphyry. . . . . These veins occupy lines of profound fissuring cutting the schists on both the strike and the dip, and their filling consists of quartz carrying iron pyrites and fine needles of tourmaline. The observable proportion of original and secondary carbonates (dolomitic content) is generally lower than that of the Hollinger ores, and distinctly lower than that of the Dome run-of-mine."

Segregation of Gold

Again: "The highest gold values appear to result from the association of quartz, tourmaline, and pyrite. . . . . This association is most predominant towards the centre lines of the veins, while the tourmaline thins out and disappears and the pyrite becomes less plentiful and takes on more marked crystallization towards the walls of the veins. The walls themselves carry low gold values for varying widths from the veins proper. In most veins of the Porcupine area quartz and carbonate form the basis of the vein filling. Generally silica predominates strongly over the carbonates in the Ankerite deposits, but there are some portions of the veins where carbonates predominate and here the gold content is reduced. This is characteristic of all Porcupine veins . . . . . When tourmaline appears in Porcupine ores it generally implies a high gold content, although this fact does not seem to have been much noted. . . . At certain points, pipes and masses of porphyry are mixed with the vein-stuff and, although not highly gold bearing in themselves, in fact tending to reduce the grade of the total to be mined, they appear to enrich the vein-stuff proper at such points. This is typical of the action in the ore bodies of Porcupine. It is desirable, perhaps essential, in proximity to the veins, but undesirable when intermixed."

General

In the Porcupine zones of schisting, gold is very widely distributed. No veins are entirely barren. But only under certain favourable and discoverable conditions are veins payable. The metal has been deposited thinly except where the right combination of conditions has prevented its dissipation and, by local stoppage of the gold-bearing solutions, has forced these solutions to deposit their load.

"Obstructions, as well as openings," says Penrose in his excellent paper * on ore shoots, "in a fissure may in some cases have an influence on the position of ore shoots. Obstructions may occur where the walls are locally pressed together, or where the fissure makes a curve or is faulted.

"Any of these obstructions may influence the formation of ore shoots by locally checking the speed of the ore-bearing solutions that come in contact with them, thus encouraging deposition."

Summing up, then, the points that the writer seeks to emphasize are:

1st. Gold-bearing schists in the vicinity of porphyry do not in themselves constitute ore.

2nd. The presence of quartz veins, schist, and porphyry

*Some Causes of Ore-Shoots, by R. A. F. Penrose, Jr.

does not necessarily imply the presence of payable ore.
3rd.—The pre-requisite for the deposition of payable ore has been structural deformation of the fissures that lie within the schist.
4th.—There is a genetic difference between the mineralization of the veins and that of the schist.
5th.—Whilst enrichment need be looked for only under the right conditions, the right conditions may be found without the gold.
6th.—The chief function of the intrusive porphyry has been to release the ore-making solutions that filled the fissures ready for their reception.

Canada's Mineral Resources

DR. CORLESS DEMONSTRATES THAT SOUND DEDUCTION IS THE BASIS OF PROGRESS

To the Editor, Canadian Mining Journal.

Sir, — Absence for about two months delayed my reading of recent issues of the *Canadian Mining Journal*. I have no desire to prolong the controversy begun in the C. I. M. M. *Bulletin* regarding the extent of Canada's Mineral Resources, which is one of the main subjects Mr. Campbell discusses in your issue of November 3rd. However, the statistics he furnishes, valuable as they may be for other purposes, are so entirely valueless as a contribution to the discussion of this matter, and the inferences he draws from these statistics are so unjustifiable, that I am not surprised that he has learned so to distrust his own reasoning regarding our national mineral resources as to discard the use of inference altogether and to pin his faith to observation and measurement exclusively—a method quite essential in estimating the ore reserves of a developed mine, but wholly useless for forecasting the extent of national mineral resources. But let me repeat what was said last March: "The mining engineer who does not look beyond the ore he can measure, who is not intent on using ascertained facts as a stepping stone to probabilities, will not get very far." Mr. Mickle has shown mathematically, as I have in more general statements (in order to reach a wider circle of readers), that the probability in the case under discussion is so great as to reach a higher degree of certainty than that obtaining in the case of results usually accepted as estimates of ore reserves. The greatest fallacy underlying both this letter and those of Mr. Campbell published in the C. I. M. M. *Bulletin*, is in the unwarranted assumption that since we cannot estimate our national mineral resources as we do the developed ore in a mine, we are not justified in making any inferences as to their extent.

Our Mineral Wealth is Potential, but Real

After making the familiar reference to misuse of statistics, Mr. Campbell invites your readers to judge whether he has drawn any unwarranted conclusions from those he gives, which invitation I am accepting. He then prefaces his first statistical table with this statement: "The annual mineral production is, generally speaking, an indication of the mineral wealth of a nation" (country?). If "nation" is not used in the sense of "country", as I have suggested in parentheses, then the statement is meaningless in this connection. If it is used in this sense, the statement is so absurd as hardly to need refutation. The mineral wealth of Canada (using the expression, 'mineral wealth,' in the sense already defined in the C. I. M. M. *Bulletin*, which sense he has already accepted) was in existence before the white man occupied the country, as well as when the early white settlers were too busy with hunting, fishing and clearing their farms to give any serious thought to the minerals of the country they were beginning to occupy.

But this is the very crux of the discussion. As I pointed out last March, in the pioneer stage of development of a country, which stage Canada has not yet left wholly behind, there is, broadly speaking, a natural succession to the beginning of its basic industries. In this succession, unless the development is carried on as foreign exploitation, mining generally comes last. This is why mining is the least developed of our basic industries in proportion to the resources with which this industry is concerned; why it is just beginning to come into its own; why the Canadian people are only now beginning to take a broader view of Canada's mineral resources; why an effort was made last March to assist Canadians to realize the meaning, from the standpoint of the mining industry, of the great physical and geological features of the country; why inferences, amounting to reasonable certainties, were drawn from these features and the important mineral discoveries already made. How then can the annual mineral production of Canada, at the present time, indicate in any way the extent of its mineral wealth? On the contrary, the present relatively low mineral production, either in total or per capita, points to the pioneer stage of the mining industry. This table of statistics, therefore, chiefly directs attention to the fact that the mining industry in Canada is as yet only in its infancy. In no sense can these tabulated figures be considered as furnishing any kind of measure or indication of Canada's mineral wealth. Similar remarks apply to the second table, giving the value of production of certain selected industries for 1918. These figures bring into clear relief the relatively pioneer stage of mining when compared with other industries. Both tables, properly interpreted, serve to emphasize the serious responsibility resting on mining engineers of making known, on every suitable occasion, the splendid opportunities Canada affords in this industry.

Present Imports should Stimulate us to Domestic Production

Mr. Campbell's next table, giving a list of Canada's mineral imports, metallic and non-metallic, points in the same direction. With very few exceptions, Canada has in abundance the raw materials (minerals) listed. This list, properly regarded, should act as a stimulant, not as a depressant, to mining engineers to redouble their efforts to direct attention to our enormous unprospected areas and to bring to the notice of the public the significance of these areas, as shown by the results already achieved and continually being obtained in similar areas already prospected. The list

of metallic and non-metallic materials imported into Canada, both in the raw and manufactured state, is no more an indication of limitation of Canada's mineral resources, than would a list of importations of farm and forest products, raw or manufactured, serve to show limitation in the extent and value of these resources. Such a list, properly interpreted, might, however, be useful in calling attention to climatic conditions in these products, but this would merely add confusion to the issue under discussion. Just so, the importations of metallic and non-metallic products, if properly interpreted, may be useful in showing the need of directing attention to the fact that we should push the exploration and development of mineral resources, or to the fact that we do not at present carry out the manufacture of certain of our metals in this country, which might usefully lead to a study of the economic reasons for this. But by no stretch of imagination can such tables, or any other statistical tables of this kind that can at present be compiled, furnish any evidence as to the extent of the mineral resources of Canada not yet mined nor even developed. For this purpose, as was clearly stated last March, "we must pass from accurate and slowly acquired knowledge to reasonable inference, if we are ever to form any kind of estimate of our mineral heritage." The inferences then made and the grounds for them were carefully stated, and have been restated, in part, in letters to the *Bulletin*, with some additional data and further grounds for the reasoning, not then permissible because of time and space limitations. Mr. Campbell has furnished some useful information and offered interesting criticism in his letters to the *Bulletin* and *Journal*. But what he has said has served rather to confirm, to bring out more clearly, and to emphasize the soundness of the reasoning employed at the last annual meeting, than to discredit the conclusions reached or to prove the fallacy of the method employed in reaching these conclusions. For these further opportunities to clear up any obscure points and to re-emphasize the importance of our mineral resources, I have to thank Mr. Campbell. Never in any single year has more additional evidence been added, pointing to the substantial soundness of the inference regarding Canada's mineral resources then made, than in the year now nearing its close. I can only hope that the discussion then and since has been of some assistance in directing the mind of the public to these.

Coal Reserves

Far too much credit is given me by the author of this letter in referring to my "statement that we have 1231 billion tons" of coal and lignite. I was at considerable pains to give Dr. Dowling the credit for compiling these figures for the coal report of the Twelfth International Geological Congress, from which I explicitly stated that the figures were *culled*. If Mr. Campbell knows of a later or more dependable figure, he will confer a favor on your readers by giving it. Nor did I say that this fuel would be "*good for* 35,000 years, at the present rate of consumption." Let me quote what I did say: "This inconceivably large figure 1231 billion of tons, roughly 35,000 times Canada's present total annual consumption, baffles the imagination. It is nearly sixty per cent greater than the estimated reserves of the whole of Europe, nearly equal to those estimated for the whole of Asia, and one-sixth of those of the entire world." This is very different from saying that our coal and lignite resources would be "*good for* 35,000 years." No such idea entered my mind. These statements, by any unprejudiced reader, will be understood as they were intended — to assist the mind to come as nearly as possible to grasping what this baffling figure means. We do not need to consider what percentage of this vast quantity of fuel may appear at present to be of little or no value. Our greatest fuel problem is not possession, but transportation — a problem not yet seriously tackled, but one which Canadians are sure to tackle in the not distant future.

The Optimistic Engineer

You have done me the honor of calling me an 'optimistic engineer', whatever this may imply. Optimism, if I understand the word correctly, expresses the view or belief that everything in nature and history is ordered for the best. Hence an optimist must believe in the ultimate good of everything, even of seeming evil. I am unaware of any statements of mine that imply that I hold any such view. But I *am* a believer in scientific method; in scientific induction and deduction as among the most powerful instruments the human mind has forged for the advancement of knowledge, provided always that these methods of reasoning are soundly based. Nothing is more dangerous than a seeming induction or a superficial deduction. Many engineers, I fear, allow their minds to become so engrossed with their daily grind as to fail to grasp the great power of reaching out into the unknown and of drawing reliable conclusions, which these mental instruments place at their disposal. Facts and data alone are dead material. They become significant, vital, of far-reaching import, only when they are gripped and interpreted through these mental processes. If the belief, that human progress must come chiefly by trusting and accepting the results of human reason as a basis for action in mundane affairs, entitles me to your application of the epithet, 'optimistic engineer', then I have no objection to your use of the term.

C. V. CORLESS

Coniston, Ontario.

The cost of experimental research on a commercial blast furnace is prohibitive, due to the enormous investment required to build a single stack and its perquisites and the cost of a "freeze up" which would inevitably attend destructive experimental work. Still, the reactions in the blast furnace are far from perfectly known, and full knowledge might be of incalculable value. Consequently the United States Bureau of Mines has erected, at its station in Minneapolis, a small blast furnace in which it is hoped to conduct a thorough research. [illegible] and has been found to [illegible] satisfactorily the operation of the full-sized stack.

There has been discovered lately on the northwest part of the Transvaal near the border of Bechuanaland a stratum of "banket" that has been [illegible] to be gold bearing to the degree of [illegible] at least some spots. It is hoped that further [illegible] will show that the gold [illegible] be sufficiently large to warrant [illegible]. It has been commonly reported in South Africa during the past year that "another Rand" [illegible] do not warrant this conclusion.

Mining Engineers in England

INSTITUTION OF MINING ENGINEERS HOLD ANNUAL MEETING

By ROLAND H. BRIGGS

The annual meeting of the Institution of Mining Engineers in London (England) on November 16 and 17, was of even greater social and technical interest than usual. H. R. H. The Prince of Wales attended the dinner that the Institution, together with the Institution of Mining and Metallurgy, gave on the first day, and at which the Medal of the Institution of Mining Engineers was presented to Sir George Beilby, LL.D., F.R.S., in recognition of his contributions to science, with special reference to his researches on fuel. At the opening meeting the President, Professor Sir John Cadman, K.C.M.G., D.Sc., presented the report, and referred with special cordiality to the visit of the representatives of the American Engineering Societies and to the election of Mr. Ambrose Swasey and Mr. William Kelly as Honorary Members of the Institution at that time.

Sir John Cadman's Presidential Address

Sir John Cadman subsequently delivered his presidential address, emphasised the work the Institution was doing towards the prevention of accidents in coal mines and the problems relating to the winning aand working of collieries, ventilation, and the advancement of the general science of mining engineering, and showed how very greatly the percentage of fatal accidents in coal mines in Britain had been reduced during the past seveuty years. He suggested that the Institution should concentrate strongly on the problem of explosions from coal-dust.

In a very important paragraph he also said, "Our two Councils, (those of the Institution of Mining Engineers and Institution of Mining and Metallurgy) have adopted a proposal for the formation of an Empire Council of Mining and Metallurgical Engineering. The sister Institutions in the British Isles and the Dominions will be invited to co-operate with us as equal partners in the constitution of its Council. Its functions will be to create and maintain throughout the Empire a high standard of technical efficiency and professional conduct; to strive for the safer working of mines within the Empire; to convene at regular intervals an Empire Mining Congress, the first to be held in connection with the British Empire Exhibition in London in 1924, and subsequent congresses in the Dominions; to establish, if thought necessary or desirable, a Register of British Mining and Metallurgical Engineers; and to serve as a medium of communication between the co-operating Institutions and to promote the interests of the professions and industries connected with them."

Spontaneous Combustion by Crushing

Five technical papers were read and discussed at the meeting. The first of these was by Professor Henry Briggs, D. Sc., Ph. D., on the possibility of spontaneous combustion being initiated by the heat produced in crushing. A rise in temperature is produced when any rock is crushed, owing to the conversion of mechanical energy into heat. It is possible that sufficient heat to start the process of self-heating may be evolved in this way during the crushing of coal in pillars and wastes. The object of the investigation carried out was to investigate whether this, the primary or physical effect of crush, is one of the responsible agents in spontaneous combustion.

Professor Briggs dealt with the expenditure of energy involved in cruhing rocks, and the conversion into heat of the work done in crushing, with the experiments of Mallet, with data that have been obtained from the use of coal pulverisers, and from the crushing of coal measure shale, with the rise of temperature in the mass of mineral after the heat developed in crushing has permeated the mass, with the relation between the size of the particle and the mass temperature, and the whole action of crushing. The paper went into the subject with great detail and a good deal of mathematical data was given.

The investigation has led Dr. Briggs to conclude that the production of heat by the act of crushing or grinding coal or carbonaceous shale is one of the causes leading to the spontaneous combustion in mines, and in the majority of cases where it comes into play the direct thermal action of crush is probably confined to warming up the fractured particle sufficiently to start accelerative oxidation, which may be followed by active combustion. The rise of temperature induced by crushing is inversely as the diameter of the fragment produced. In a coal liable to spontaneous heating whether a crush or squeeze initiates such heating depends on the proportion of fine particles produced, since fine particles gain a higher initial temperature and offer a greater surface for oxidation.

A fragment of average bituminous coal 1/300th. inch in diameter, if suddenly produced by crushing, will, in the midst of similarly conditioned particles, obtain a temperature rise of about 52 deg. Fah. If the waste in which the crush takes place has a temperature of 75 deg. Fah. this particle will thus be raised, practically instantaneously, to a temperature of 127 deg. Fah. Under the same conditions a fragment 1/100th of an inch across will attain a temperature of about 92 deg. Fah. The importance of temperature rises of the size referred to in the initiation of spontaneous heating is shown by the fact that the difference between summer and winter temperatures in Britain, only about 23 to 24 deg. Fah., has a considerable effect on the firing of coal cargoes on ships. The heat of crushing is generated at the surfaces of the fracture and rapidly distributed through the particle. The temperatures produced by crushing hard rocks suddenly and finely are considerable. The rise in temperature from crushing coal measure shale is about 50 per cent. greater than that due to crushing average bituminous coal and where shale is more subject to spontaneous ignition that the coal in its vicinity, this may be due to its greater liability to crush or to the greater heat which it yields in crushing.

Mine Fires from Pyrites

An interesting paper on the spontaneous heatings and fires in the pyrites mines of the Huelva district in Southern Spain was submitted by Mr. A. O. Brown, B. A. This paper was the fifth report to the committee on "The Control of Atmospheric Conditions in Hot and Deep Mines." The ore is mainly an intimate mixture of iron pyrites and chalcopyrite, known as cupreous iron pyrites. The copper content averages about 1.5

per cent., sulphur 45-47 per cent., iron 40 per cent., with small quantities of zinc, arsenic and lead ,and from 5 to 10 per cent. of insoluble silicate of alumina. The ore bodies are generally of great size, frequently 10 to 40 metres wide, or even wider. The lengths of the masses vary from a few hundred to 2000 metres. The depths vary from 100 to 500 metres.

The fires occur in the secondarily enriched zone where the softer and more easily oxidised chalcocite occurs, or in primary ore of unusual softness that has moved. It is believed that timber spreads but does not originate the fires. Spontaneous combustion caused by oxidation is the probable cause of all the true mineral fires. The fires are very difficult to extinguish, especially so near old workings where timber and blocks of ore have been abandoned among loose filling. In some cases flooding has been resorted to but usually cooling by means of the introduction of large volume of low-pressure air is advisable, as well as the mining out, as soon as possible, of the mineral in the troublesome area. The mineral probably approaches a temperature of red heat when on fire. Sulphur dioxide is prduced in large quantities and the oxygen of the air diminished. After fires, the air in the working faces in the zones was not allowed to exceed 131 deg. Fah. and it was seldom possible to reduce it below 122 deg. Fah. Some kind of gas mask or respirator is usually employed, sponges, wollen respirators soaked with a 20 per cent. solution of sodium carbonate and Kolnig being used in different places, according as to whether the temperature or the dust and gas was the most serious trouble.

Subsidence of Land above Mine Excavations

The third paper read was by Professor Henry Louis, M. A., D. Sc., and concerned the problem of subsidencies. Professor Louis referred to the fact that in legal cases for claims for compensation sympathy is always with the surface owner, and in the absence of any clear theory with regard subsidencies it is difficult to prove that the colliery did not do the damage. If a coal seam is worked out to a certain line there will be a subsidence above the part worked out and a subsidence of gradually decreasing amount will extend backwards from the standing face, which is known as "draw". Careful measurements have shown that the average angle of draw in ordinary coal measure strata lying practically horizontal is between 5 deg. and 15 deg., being lower as the proportion of sandstone is greater and higher as the proportion of shale is greater. In Secondary strata the draw is about 25 deg. and in Boulder Clay or similar formations from 20 to 35 deg.

The amount of vertical subsidence to be expected in any given case cannot be predicted with any degree of certainty, for want of a sufficient number of recorded observations. When a coal seam is worked out over a considerable area, the immediate roof of the seam subsides by an amount equal to the thickness of the coal removed, but the strata are shattered and never squeeze down to their original form. Thus the surface settlement is never as great as the thickness of coal removed, but Professor Louis does not believe that there is any depth at which surface subsidence becomes zero. Professor Louis tentatively suggested a formula for calculating subsidence but pointed out that it was merely empirical, but corresponded to observed facts in a number of cases.

Breaking Down Coal by Gases

The fourth paper was also of a theoretical nature, by Dr. Rudolf Lessing, who described investigations he had carried out on the disintegration of coal by acids. He suggested that the getting of coal might be facilitated by the introduction of gaseous acid into the coal face through boreholes. Sulphur dioxide is used and is taken from a compressed gas cyplinder and passed through a water bubbler by means of acid resisting tubes into the coal at practically atmospheric pressure. It is absorbed by the coal and there is no smell. The coal is disintegrated and the cost of the gas is only small. Blasting would be eliminated. The scheme, of course, bristles with practical difficulties, as members pointed out. By a practical experiment at the end of the meeting, Dr. Lessing, however, certainly demonstrated to members that the gas undoubtedly had the effect claimed of disintegrating the coal.

A New South Wales Coal Field

The fifth and last paper of the meeting was a description of the "Greta and South Wales Coalfields, in New South Wales," by Dr. J. R. M. Robertson. In this description the field was very fully dealt with, the origin, geological features, methods of coal getting, labour conditions, chemical and physical properties of the coal, history of the field and details of some of the individual collieries, being included.

The paper was closed with a warning with regard to the field. The coal resources of New South Wales are often believed to be sufficient for thousands of years, but this is not the case. The majority of the known seams are of inferior quality, and for these so far there has been an insufficient demand. The output of the State has been drawn solely from a few really good seams, and these are fast hastening to their end. The greater part of the reserves doubtless exist under difficult and inaccessible ground and are practically unproved.

The meetings at which these papers were read were well attended by representative and influential mining engineers, and it is perhaps important to point out that the three suggestions relating to the initiation of spontaneous combustion by the heat produced in crushing, the theory with regard to subsidencies, and the use of sulphur dioxide for the disintegration of coal under ground, were somewhat adversely critisised by many members present.

PROGRESS ON CONTINENTAL

Private advice from New York is to the effect that Mr. R. C. Warriner, president of Continental Mines has returned recently from an inspection of the properties at Cobalt and Kirkland Lake. He is reported as quite enthusiastic over a recent discovery on the Kirkland property by means of surface trenching. A promising ore body has been disclosed on surface and has been traced for some distance, with most encouraging assays. Mr. Warriner has instructed the local manager to start sinking a shaft immediately.

As Mr. Warriner is a mining engineer of long experience in gold mining, it can be assumed safely that Continental has now, after a full season's geological study and trenching, located its first undoubted ore shoot. Having delineated it by stripping on the surface in its horizontal direction the management will now examine its size and grade in a vertical direction. Unless the Continental product should prove to be radically different from the adjoining Kirkland properties on the same break, it has now commenced definitely on a career of productiveness.

It has been demonstrated that, on account of mineral difficulties in handling and excessive dust losses, it cost approximately $5 a ton more to smelt one flotation concentrate than gravity concentrate.

Canadian Graphite to Lead in the World's Market*

Ceylon Mines, Practically Exhausted—Canadian Product Equal in Every Respect — Flotation Process Makes Production Profitable

By H. P. H. BRUMELL

Graphite is a mineral and an allotropic form of carbon of which charcoal is the lowest and diamond the highest form. It is crypto-crystalline, steel grey to black in color, lustrous, lubricous, scetile, very soft and has a specific gravity of from 2.1 to 2.3. It is also highly refractory and has high electric conductivity.

The mineral is known under three names: graphite, plumbago and black-lead, which are used in the trade to distinguish the three different forms in which it occurs, thus: the word graphite is used for the flaky product derived from disseminated ore, plumbago for the crystalline material filling veins or pockets, and black-lead for the earthy or so called amorphous variety. According to the country of origin the trade also uses the three synonyms, thus: Ceylon plumbago, Canadian or American graphite and German black-lead.

Graphite is a prosaic mineral and but little known to the general public, the average layman thinking of it only in connection with pencils and stove polish or as a lubricant in connection with automobiles. No glamour attaches to it as in the case of the precious metals yet it is probably a much greater essential than either gold or silver, nor has any substitute been found for it in its principal uses. It is absolutely essential in the melting and moulding of most metals, in electricity, certain lubrication, lead pencils and stove polish, and is used in a variety of other purposes, the proportions entering into the various trades being approximately as follows:—

Crucibles and refractories	65%
Lubricants	10%
Foundry facings and stove polish	10%
Pencils	7%
Paints	3%
Other uses	5%

If value rather than quantity be considered over 75% should be credited to crucibles and refractories.

In nature the mineral is found in two forms known to commerce as crystalline and amorphous, the latter being very widespread in its distribution, while the crystalline variety is restricted, being confined to crystalline rocks of pre-Cambrian age or metamorphic crystalline rocks of a later period. Thus the disseminated graphites of Canada and New York states are of pre-Cambrian age while that of Alabama occurs in highly metamorphosed sediments of the Carboniferous series. For the purpose of this paper consideration of the crystalline variety only will be had.

Crystalline graphite occurs in commercial quantities outside of Canada in Ceylon, Madagascar, Bavaria and in the United States. In Canada the deposits are in Central and Eastern Ontario, in Labelle and Argenteuil counties, Province of Quebec, and on Baffin Island, the largest and most important being located in Buckingham township, Labelle county. Examining the foregoing occurrences both as to quantity and quality, it may be said that the product of Ceylon is probably the best known but, unfortunately, the deposits have been almost completely depleted and it is the express opinion of those most familiar with the field that it is only a question of a year or two before it is entirely exhausted. The field is small, as has been ascertained by the geological survey of the Island, and it has become a question of deep mining under very expensive conditions as the veins are very narrow and the occurrences such as to preclude systematic mining. In a confidential report to the Department of the Interior, Washington, July 7, 1918, by H. G. Ferguson and F. Grout, the following statement is made:

> "Although no definite data are available, it is believed that the production of Ceylon cannot go on much longer at its present rate and it is possible that the virtual exhaustion of the deposit is not far distant."

Madagascar has extensive deposits of disseminated ore but the refined material has been found unsatisfactory for the manufacture of crucibles, the most important of all uses to which graphite is put. In Bavaria there are somewhat extensive beds of low percentage dissiminated ore from which a very small sized flake is obtained and used locally. The field is not important. In the United States the only important fields are those of New York and Alabama, the ore, a disseminated one, averaging about 5% in the former and 2½% in the latter.

In Canada there are practically unlimited quantities of disseminated ore, assaying from 10% to as high as 30%. Of the known fields of the world those of Canada are by far the most important in extent, percentage of graphite content and quality of product. As may be seen on reference to the list of uses of graphite the making of crucibles is the most important, and it is for this purpose that the Canadian material excels, and it is through this use that Canada will in the next few years, dominate the world's graphite industry. During the past few years the governments of the United States, Great Britain and Canada have been making exhaustive enquiries and investigations as to an alternative source of supply of crucible graphite with the result that Canada has been shown to be the logical successor of Ceylon, which has hitherto supplied the world with this particular material. It was not, however, until the advent of the oil frothing flotation method of concentration had been perfected that it was possible to supply Canadian graphite at a price which allowed any profit to the producer. This perfection of process, coupled with the depletion of the Ceylon fields, makes the Canadian graphite industry a most profitable one.

A comparison of costs of production of crucible graphite, according to governmental and authoritative statement, shows the following:—*Ceylon.* All material shipped in crude form. Average cost per ton, f. o. b. port in Ceylon, about $112.00, according to report of United States consul at Colombo, January 1921. To this price must be added freight, insurance, commission, etc., and before the material is suitable for any purpose it must be milled and refined at considerable cost, the total increase over actual cost f. o. b. Ceylon being probably 40 p. c. *United States.* From "Information concerning Graphite" Committee on Ways and Means, House of Representatives

* From *Canadian Foundryman.*

Washington, 1919, it is learnt that the cost of production of graphite in the United States ranges from $120.00 to $280.00 per ton. *Canada* It has been proved at several mills that, from an ore assaying 10 p. c. only and with an extraction of 90 p. c. only of the graphite content the cost of production, with oil frothing flotation, is less than $50.00 per ton f. o. b. rail. From records in possession of the writer the factory cost at one mill was $44.00 per ton and at another approximately $47.00. It must be borne in mind that the Canadian material is finished and of high grade as against the crude material of Ceylon.

The following official assays of No. 1, or crucible stock, produced by Canadian mills as well as those of foreign graphite attest the superiority of the Canadian material:

Anglo Canadian Graphite Syndicate, 94.68%; assayer, A. E. Tucker, Birmingham, Eng.

North American Graphite Co., 96.30%; assayer, M. L. Hersey, Montreal.

North American Graphite Co., 94.40%; assayer, Mines Dept., Ottawa

Buckingham Graphite Co., 95.00%; assayer, Durand Woodman, New York.

Buckingham Graphite Co. 98.08%; assayer, M. L. Hersey, Montreal.

Dominion Graphite Co. 94.30%; daily average for two years.

Alabama 87.03%; assayer, United States Bureau of Mines.

New York 88.97%; assayer, United States Bureau of Mines.

Pennsylvania 88.80%; assayer, United States Bureau of Mines.

Ceylon 85.06%; assayer, United States Bureau of Mines

Madagascar 88.50%; "Foreign Graphite" A. H. Redfield.

For crucible making, size of particle, weight for bulk and purity are all important, and in these respects Canadian graphite is pre-eminent. In the matter of weight the specific gravity of the Buckingham, Que., material, according to G. C. Hoffmann, Geological Survey of Canada, 1876, is 2.2685, while that of Ceylon, according to the same authority, is 2.2591, and, according to F. G. Moses, United States Bureau of Mines, the Alabama product has a specific gravity of only 2.1. Regarding the size of particle, the crucible manufacturer's specification demands an evenly-balanced stock between the limits of 16 and 90 meshes to the inch which size is, of course, easily obtainable from the crude lump ore of Ceylon, the only disseminated ore affording a similar stock being that of Canada. The following table shows a comparative screen test of No. 1 produced in Buckingham, Que., and Alabama, U.S.:

Screen mesh.	Buckingham No. 1 Separate p.c.	Buckingham No. 1 Cumulative p.c.	Alabama No. 1 Separate p.c.	Alabama No. 1 Cumulative p.c.
On 30	4	4	..	..
On 40	16	20	11	11
On 50	18	38	..	..
On 60	30	68	37	46
On 70	27	95	..	..
On 80	3	98	30	78
On 90	2	100	15	93
Through 90	..	..	7	100

The Buckingham stock, above, was produced under the old and very destructive method of dry concentration,

Entrance to one of the Workings of the North American Graphite Co., Buckingham Township, Quebec

while the Alabama material was produced by means of flotation whereby the size of particle is maintained. Notwithstanding this handicap in the methods of concentration it will be noted that 68% of the Buckingham stock stood on 60 mesh as against only 48% of that of Alabama, a very pronounced superiority in favor of the Canadian product.

The market for graphite is a constant one and is rapidly growing as its uses are becoming more generally known. Of late years there has been a tremendous growth in the demand for the mineral in the iron and steel and non-ferrous metals trades in electricity and for lubrication in which latter regard it is now being more fully appreciated. The markets of the principal consuming countries are approxmiately as follows:

Germany	40,000 tons	per year
United States	35,000 tons	per year
Great Britain	20,000 tons	per year
Austria	10,000 tons	per year
Czecho Slovakia	10,000 tons	per year
France	5,000 tons	per year
Italy	5,000 tons	per year
Belgium	5,000 tons	per year
Japan	5,000 tons	per year
All others	15,000 tons	per year
	150,000 tons	per year

The world's production since 1900 shows a steady and marked increase, irrespective of the disturbed years of 1914-1918, as follows:—

1900— 81,683	tons
1901— 78,920	tons
1902— 81,901	tons
1903— 97,673	tons
1904—100,643	tons
1905—118,938	tons
1906—124,187	tons
1907—143,930	tons
1908—106,741	tons
1909—123,382	tons
1910—116,004	tons
1911—125,560	tons
1912—136,510	tons
1913—150,325	tons
1914—115,068	tons
1915—124,339	tons
1916—202,287	tons
1917—238,683	tons
1918—226,024	tons
1919—172,579	tons

In conclusion the writer would draw attention to the opportunity afforded to create, in Canada, an industry which would certainly dominate the crystalline graphite market of the world. It is a trite saying that "crystalline graphite occurs only in crystalline rocks" and of these we have in Eastern Canada the greatest development in the world covering, as they do, nearly the whole of the provinces of Ontario and Quebec. As has been stated the world is now looking for a new source of supply of crystalline graphite and it is understood that the Imperial Mineral Resources Commission is carrying on investigations with a view to aiding in the development of the graphite resources of the Empire as well as those of other refractories such as magnesite, talc, soapstone, etc. Dr. Charles Camsell, Deputy Minister of Mines, Ottawa, was recently in London in connection with this work. Many reports of both the Federal and Provincial Governments give evidence showing the great extent of our graphite land and the value of the ore and product as well as information concerning the treatment of the ore, markets, etc. That the

One hundred ton mill of the North American Graphite Co., Buckingham Township, Quebec.

United States Government is alive to the situation is evidenced by the many reports on both domestic and foreign sources of supply.

Careful investigations by prominent engineers and mining men of both Canada and the United States have shown that we have in Canada all the requirements for a very large and stable industry, the consensus of opinion being that it is a milling rather than a mining problem. The graphite occurs as a rock constituent of enormous masses of gneiss and limestone, the question of production being solely a matter of profitable concentration. The finished material has always been acknowledged to be of the highest grade and eminently suitable for crucible making, though it was not until the exigency of war-time forced it that it was openly acknowledged. Until 1914 it was understood by users generally that only crucibles made of Ceylon graphite would stand up to their requirements. World conditions, however, during the war changed all this, and it was proved that some of the other crystalline graphites were fully equal to Ceylon and the prejudice which had been fostered by Ceylon producers for nearly 100 years was broken down and the crucible maker now cheerfully acknowledges that he is willing and anxious to get his supply of suitable graphite where he can. Commenting on conditions in the Ceylon trade the "Report of Inspector of Mines, Ceylon," 1920, says:

> "In previous years there have been slumps in the industry, due to temporary lack of demand for plumbago, but the present slump is an entirely different matter, as the demand for plumbago is as great or greater than it ever was, only, unfortunately for Ceylon, the supplies are being obtained from elsewhere. The position could not very well be worse than at present."

The writer is in possession of the records of several mill run tests showing that an average extraction of 96.14% of the graphite content of the ore was recovered from ores averaging 15.41%, all in the Province of Quebec. For reasons that are obvious to the writer no reference to specific properties may be made though he is permitted to make public certain results obtained. At one property in the Province of Quebec a recovery of 97.84% was made from an ore assaying 13.75%. Of the finished material 56% was No. 1 or crucible stock, 19% was No. 2 or lubricating stock, and 25% was No. 3 or ground stock, the three grades assaying 94.40%, 90.25% and 73.10% respectively. At present market prices these would have an average value of $130.00 per ton, while the factory cost of production would be $44.00, a profit of $86.00 per ton of finished material, or a profit on each ton of ore milled of over $12.

If there be such a time as a physychological moment, that moment is certainly the present one in the matter of graphite mining and milling and it is to be hoped that for the credit of Canadians and their well known pride in their country's natural resources, the people of this country will take advantage of it. Our graphite is acknowledged to be the best for all purposes, the ore deposits are almost unlimited, the percentage of the graphite content is the highest known, the system of concentration has been perfected and, as the market is a large one and growing as the use of the mineral becomes better known, there are all the necessary factors for the making of a large and very profitable industry.

COAL PRODUCTION COSTS

Until a few years ago the accounting systems of the majority of coal operators of this country were extremely crude, and in many cases practically worthless. The National Association of Cost Accountants has published an article entitled "Coal Production Costs", by R. W. Gardiner, Commissioner of the Pittsburgh Coal Producers' Association, that will be found of great value as it bears directly upon accounting problems in this very important industry.

Before going into the technique of cost accounting Mr. Gardiner mentions the uses made of cost data by the operating, sales and finance departments, respectively. In connection with the payroll analysis which follows, he discusses the distribution of the three classes of labor in a mine, namely, direct (mining), indirect, and maintenance and repairs, and to what extent the superintendent or head of the operating department can control those divisions.

It is in the second, or indirect labor division, that the greatest leaks occur, in most businesses, and the coal industry is not an exception in this respect.

The distribution of supplies, and the royalties, depletion, depreciation and obsolescence are treated briefly. The differentiation between capital and operating charges is not as difficult to make in the case of a mine and other enterprises with wasting assets as it is in other lines of industry. In regard to charges to capital the author says:

"All development work after the opening of a mine is a proper charge against the cost of operations. This statement is based on the theory that no charges should be made to capital account unless the expenditure either results in an increased production or decreased costs."

At the conclusion of the booklet is an appendix prepared by the Research Department of the National Association of Cost Accountants. This appendix includes a summary of the main features of the uniform cost system of the National Coal Association, a summary of a system adopted by a number of Anthracite Coal Operators, and a brief note about two cost systems in the retail coal field.

Throughout the discussion there is a generous sprinkling of footnotes explaining certain technical terms peculiar to the coal mining business and foot notes referring to sections of the cost system of the National Coal Association that bear on or amplify points discussed in the main body of the text.

Copies of this pamphlet may be obtained from the office of the Secretary, National Association of Cost Accountants, 130 W. 42nd Street, New York. The price to non-members of the Association is seventy-five cents per copy.

The oil shales of Colorado have been explored with more thoroughness than those in most other parts of the world except where they have been worked, as in Scotland and Australia. The Colorado shales underlie an area of 16,000 square miles and are estimated to be capable of producing 20 billion barrels of oil and 400 million tons of ammonium sulphate.

Experimental work on the carbonization of lignite is being conducted in France with a view to making that country independent of foreign petroleum. If successful, considered by certain French technologists that will be granted the commercial success of this although France will still need to import oil.

LETTERS FROM READERS

The Institute's Professional Members

The Editor, Canadian Mining Journal.

Sir — In an editorial entitled "The Institute's Usefulness" which appeared in your issue of November 24th, you make the following statement:

"During the quarter-century of the Institute's corporate existence the practical direction of Canada's mining industry has passed gradually into the hands of technically trained engineers, the bulk of whom are now registered as Professional Members. The professional conduct of these engineers, and accessions to their ranks, are subjected to no systematic scrutiny, and are subject to no control outside the purely formal addition of their names to the Institute's list of Professional Members."

Just how you would propose to scrutinize the professional conduct of Professional Members is not stated in your article. I would, however, remind you that Article 13 of the By-Laws of the Canadian Institute of Mining and Metallurgy states that "any member may be expelled from the Institute for cause (on the recommendation of five members of Council or of any ten members of the Institute in good standing) by a two-thirds vote by letter ballot of the whole Council."

I would also draw your attention to announcements published on pages 722 and 723 of the June Bulletin of the Institute, which indicate very clearly that candidates either for election into the Institute or for transfer from one grade to another are subjected to careful scrutiny by—

(1) The names of candidates for admission to either membership or associate membership are posted in two consecutive issues of the Monthly Bulletin, after which these applications are handed to a Membership Qualifications Committee for consideration and recommendation to Council.

(2) Applications for transfer from one grade of membership to another are posted in two consecutive issues of the Bulletin before being presented to the Membership Qualifications Committee, who consider same and make their recommendations to Council.

In the case of Professional Members, the applicant for this grade must supply the Membership Qualifications Committee with minute details of his education and experience and must also submit the names of at least five members who shall satisfy the Committee as regards the fitness of the applicant.

Election to Professional Membership in the Institute, therefore, requires—

(1) Satisfactory replies from at least five sponsors to the Committee's request for information.

(2) That a summary of the applicant's career be brought to the attention of the members of the Institute through the Monthly Bulletin.

(3) Classification by a Committee appointed by Council, after a month has elapsed from the time that all members have been notified.

It is evident from the above that classification as a Professional Member of the Institute entails certain formalities, requiring on an average three months from the day the application is received before applicant can be admitted to this classification. It would appear, therefore, that you were not conversant with these requirements, otherwise you would not have stated that the addition of names to the Institute's list of Professional Members was a matter of pure formality.

GEO. C. MACKENZIE,
Secretary-Treasurer.
C. I. M. & M.

Montreal, Que.

NOTE. — We are pleased to have Mr. Mackenzie draw attention to the care exercised in scrutinizing the credentials of applicants for Professional Membership, to which allusion has been made frequently in these pages. But, if Mr. Mackenzie had read the paragraph quoted above once more in its context, he would probably have discovered that the formality to which we referred is not the act of admission to the list of Professional Members, but the existence of that list. The list at present is merely a reference list; the Professional Members do not co-operate, as such, in any activities whatever. It is the adoption of a definite policy and an active programme by these well-selected Professional Members that we advocate.—Editor C. M. J.

WAGES DECLINE IN BRITAIN

An important factor which has contributed to the more effective competition of British traders in foreign markets is the very considerable reductions that have been made in general wage rates in this country. According to statistics published by the Ministry of Labour, covering the leading industries of the country, it is estimated that, at the end of 1920, when wages were at about their highest level, the weekly full time rates for adult workpeople in the industries for which particulars are available averaged 170 or 180 per cent. above the pre-war figures, while, as the working hours in industries generally had been considerably reduced from about 48 to 60 before the war, to about 44 to 48, the increase was relatively higher. At the end of September, 1922, however, the increase on pre-war rates is estimated to have averaged about 75 or 80 per cent., so that within a period of about 21 months, a reduction of something like 35 per cent. has taken place. This decline in one of the most important elements of production costs was the inevitable sequel to the collapse of the post-armistice boom, while it has also contributed largely to the more recent increase in trade activity and to the reduction of 500,000 since January last in the number of unemployed. Relatively to the cost of living, however, the wage reductions, as a whole, are not so startling as at first sight might appear. At the end of December, 1920, when wages stood at 170 or 180 per cent. above pre-war figures, the index number was 165, but it had declined to 78 at the end of September, 1922, against a wage decline to 75 or 80 per cent. above pre-war. On this basis the reduction would appear to be more nominal than real, but it must be remembered that the preceding figures only relate to averages and that there is a considerable disparity between the relative increases not only in different industries, but also among the various classes of workers within those industries, while the wages again vary in different districts. Certain adjustments in the relative pre-war wages received by different workers was undoubtedly necessary, but it is evident that many inequalities still exist.—Monthly Review, Barclay's Bank.

Book Reviews

NICKEL (1913-1919). — Imperial Mineral Resources Bureau—H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2. — 56 pages. Price 1s. 7½d. post free.

This little review of the nickel industry, though naturally it can add little to the comprehensive report of the Royal Ontario Nickel Commission in 1917, gives some items of information that are not generally known. The present prominence and future promise of the Katanga copper mines in the Belgian Congo give weight to the statement that the blister copper contains about three per cent. of nickel and cobalt. Nickel is recovered from the electrolytic refining of blister copper in Japan, and the recoverable amount of nickel in the blister copper produced in the United States is about one pound of nickel per ton of copper — no small amount when one considers the annual production of copper in the United States.

The possibility of using the iron in the nickel ores of Sudbury is referred to briefly. "The Sudbury ores contain about 40 per cent. of iron. In every million tons of ore treated, 100,000 tons of iron, equal to one-half the Canadian production of pig-iron, is slagged in the furnaces and lost."

It is stated that pure nickel is malleable, and that the Mond process produces nickel that is 99.8 per cent. pure. This is, no doubt, the basis of the Mond Nickel Company's new malleable nickel plant at Clearfield, Pennsylvania.

The report is concluded by a bibliography, ten pages in extent, that includes references up to the end of 1921.

IRON ORE, PART 6 — FOREIGN EUROPE AND AFRICA. — Imperial Mineral Resources Bureau—H. M. Stationery Office, Imperial House, Kingsway, London, W. C. 2. — 275 pages. — 6s. 5½d. post free.

This volume, the last of the series on iron ore to be published, is particularly concerned, of course, with the well known minette ore beds of Lorraine and the magnetite ores of Sweden, Europe's chief sources of supply outside of Britain, and the relation of these to the British supply. In terms of iron content, France has 36 per cent., Britain 23 per cent., and Sweden 11 per cent. of Europe's known reserves. Britain's ore has a lower content in iron than the other two, but enjoys the advantages of abundant coal and sea transportation within easy reach.

In spite of their low content of iron (rarely reaching 37 per cent.) the minette beds of Lorraine constitute the most important single source of iron in the world at present. Their central position in Europe gives them a value that corresponds to that of the Lake Superior deposits on the North American continent. A self fluxing mixture of various kinds of ore from these beds is used. Elsewhere in central Europe the deposits of iron ore are characteristically of comparatively small dimensions and high in silica.

Since losing Lorraine, Germany's principal resource in iron ore is high-grade siderite, high in manganese, found in veins in the Siegerland district of Westphalia and siliceous hematite occurring in sedimentary beds to the south in the Dill and Lahn basins. Though these are only of second-rate importance. Germany's control of the Westphalian beds of coking coal assure her of a position of prime importance in the world's iron and steel trade.

Italy has no coal, but has blast-furnaces on the island of Elba, where important deposits of iron ore occur as veins and lenses. In Piedmont electric furnaces are used extensively to treat ore from the Val d'Aosta.

The ores of Norway consist mainly of low-grade magnetite requiring concentration. In Sweden, on the other hand, there are in addition numerous deposits of high-grade magnetite, which have been described fully on various occasions.

Russia has numerous and important deposits of iron ore, most of these being in South Russia and the Urals. At present the iron ore industry is at a complete standstill.

Spain and Portugal have important deposits of iron ore, but the latter is unexplored, in the main. The Spanish ore is characteristically high-grade hematite. Much of this ore is convenient to sea-ports, and is shipped abroad, notably to Britain. Coal is available conveniently and in abundance ,and Spain's iron and steel industry is growing rapidly.

Though iron ore is known to be abundant and of wide-spread occurrence throughout the continent of Africa, it has been worked to any extent only in Algeria, whence considerably amounts are shipped to smelters in France.

In concluding these notices of the admirable series of volumes published by the Imperial Mineral Resources Bureau, we have only one suggestion to make. It is that, at slight additional expense, a competent draftsman could be employed to make maps to illustrate future reports that would be more in keeping with the high quality of the text.

The statistics of the mineral output of India during 1921 show the same steady increase that has been been manifested for a number of years past. Modern mining and metallurgical methods have been adopted but slowly there, and only recently has there been systematic exploration and prospecting with a view to discovering and developing mineral deposits. Part of the mineral production for 1921 is as follows:

	1920 Tons	1921 Tons
Coal	17,962,214	19,302,974
Iron ore	558,005	912,084
Manganese ore	736,439	679,286
Tungsten ore	2,310	898
Chromite	26,801	34,762
Magnesite	14,090	20,017
Tin ore	2,117	1,701
Copper ore	28,167	23,089
Bauxite	3,931	1,653

It will be noticed that, apart from coal, iron and manganese, the mineral industry of India is only fairly begun.

There is at present marked activity in the development of hydro-electric power in France, there being now over 2,000,000 h. p. in use. Most of this power is used for the purposes of electrometallurgy and electrochemistry.

England is actively engaged in providing for a nickle currency. The forthcoming budget is to provide funds for suitable machinery, and some 50,000,000 nickle coins are said to have been acquired in England and Denmark.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

GOUDREAU, ONTARIO

GOUDREAU GOLD MINES.— Work on the Murphy claims, near Goudreau, Michipicoten district, continues, though only one shift is working at present. It has not been divulged by the management whether or not mining is to continue during the winter. The surface steam pipes have not yet been covered as a protection against winter weather. The recent connection underground at the 200-foot level between the two shafts was a good one, coming within four feet in elevation and five feet laterally. It has not been made public what value or quantity of gold ore has been disclosed by these operations.

LOCHALSH.— A road has been cut from the railway to the Lochalsh property, in the angle made by the intersection of the Canadian Pacific Railway and the Algoma Central Railway at Franz, north of Lake Superior. There has been disclosed by stripping during the past season some promising gold veins on this property, and it has been taken over by a syndicate of Detroit men. All is now ready for a campaign of diamond-drilling, but this has not yet been commenced.

CLAIMS OPTIONED.— Mr. Webb, an English mining engineer representing substantial British interests, recently made a tour of the Goudreau gold area, and took options on a number of claims of some promise. No work is being done on these claims at present.

BRITISH COLUMBIA

DISCUSSION ON COAL AT INSTITUTE MEETING.— Coal Mining occupied the attention of those who attended the Annual Western Meeting of the Canadian Institute of Mining and Metallurgy held in Vancouver, B. C. from the 15th to the 17th of this month, for only one day. On the morning of Friday, the 17th inst. four papers were presented having a bearing on the industry, namely, *The Complete Gasification of Coal and its Bearing on the National Fuel Problem by* John Keillor, Vancouver, B. C.; *The Development of the Coal Industry in Canada* by F. W. Gray, Montreal; *The Coal Resources of Southern Vancouver Island* by J. D. MacKenzie, Vancouver, B. C.; and *Progressive Coal Mining* by George A. McHattie, Vancouver, B. C.

Many of the delegates took advantage of the opportunity afforded them to visit the coal mines of Vancouver Island in the afternoon, an excursion having been arranged for the two-hour steamer run across the Gulf. In Nanaimo the party was taken through No. 1 Mine, Canadian Western Fuel Corporation and in the evening another interesting business session took place. At this, a paper was presented by J. A. Richards, District Inspector of Mines, Edmonton, Alta. on the *Coal Mining Industry of Alberta.* It was followed by a paper entietled *Some Interesting Features of Modern Coal Mines* by R. R. Wilson of Victoria, B. C.

Thomas Graham, Superintendent of the Canadian Collieries (Dunsmuir's) Limited, referred in congratulatory terms to Mr. Richards' address. He had listened with great interest to his account of the progress the industry was making in the Province of Alberta. Within the next twenty-five years, he predicted, this Province would be the largest coal producer in the British Empire. Mr. Graham said that he had dug coal there in 1888 and that the advances made since that time were equalled nowhere else in Canada.

The recognition of certificates of mine official granted in one province, in all the other provinces of Canada was advocated. It was argued that if such an agreement could be reached Canadian Certificates would carry much more weight outside the Dominion than is now the case. A committee was appointed to fully investigate and report on the matter.

P. G. E. EXTENSION TO PEACE RIVER.— The Pacific Great Eastern Railway, now under construction, soon will have reached its present objective, the town of Prince George. This will give that northern interior community connection with tidewater at Squamish, Howe Sound, some miles north of the city of Vancouver. As the railway creeps further into the interior, attention becomes more and more focused upon the Peace River Country and its resources. It is suggested that the Provincial Government, in its effort to provide adequate business for the line, will be induced to extend it into that rich and little developed region.

That part of the Peace River Country which is within British Columbia has wonderful agricultural possibilities, is believed to contain oil, and is known to possess coal deposits that are likely with development to prove of great economic value.

In the year 1912, an extended report on the Coal Fields of the Peace River was made by C. F. J. Galloway for the B. C. Department of Mines. D. B. Dowling of the Canadian Geological Survey, in reports issued in the year 1915, also mentioned the Coal Fields of the Peace River.

Mr. Galloway stated that the coal-bearing formation extends along the river from near Parle Pas Rapids to Hudson Hope, or a distance of about fifty miles. Coal also is found on the South Pine and North Pine Rivers, so that the possible area of coal formation amounts to to several hundred square miles. Mr. Galloway says, "It would be obviously impossible to form any estimate of the area actually underlain by coal measures without exploring a very considerable amount of territory."

Discussing the coal seams he saw, Mr. Galloway states that thirty-four were noted along the Peace River Canyon and on Gothing Creek, but that the majority were too small to be of commercial value. It is asserted that there are only five outcrops yet known in which the thickness is greater than three feet. These five vary in thickness from three feet to three feet eleven inches, and in most of them the coal is split up by narrow stringers of shale. Regarding the possibility of larger seams occuring, Mr. Galloway says, "There is every reason to believe that many more seams exist besides those described, among which there may be a number of larger ones." Larger seams have been reported by various individuals but there is no official verification of these statements.

As to the quality of the coal, it is classified as "high carbon bituminous", an excellent grade of coal and notably low in ash. The analysis of a typical sample shows water, 2 per cent.; vol. comb. matter, 20.2 per cent.; fixed carbon, 72.2 per cent.; ash, 5.6 per cent. Mr. Galloway makes the following comment, "These analyses show the coal to be of very high grade. While not comparable with the best Welsh Admiralty Steam Coal, it is equal to a high grade of steam coal from that field and compares favourably with the West Virginia Coals, being altogether of an exeeptional quality for Western America."

Summing up, Mr. Galloway asserts that the present known seams appear to be somewhat small for economie mining. The field, however, is large and is unexplored exeept along the rivers. As it is quite undeveloped, there is a reasonable probability that commercial sized seams will yet be found. The field is a potential asset of considerable importance.

Groundhog Coal Field.—Another undeveloped British Columbia coal field is that known as "The Groundhog", situated on the headwaters of the Skeena, Stikine and Nass rivers and lying partly in the Stikine, Skeena and Omineca Mining Divisions. The shortest route to it at present is by pack-trail from Hazelton, on the Grand Trunk Pacific Ry., a distance of 140 miles. Three railway routes to the district have been considered at various times and they vary from 125 to 200 miles in length.

Wm. Fleet Robertson, Provincial Mineralogist, reported on the field in 1912; G. S. Malloch, of the Geological Survey of Canada, made a detailed examination of the same in 1911 and 1912; and there also are reports by James McEvoy, George Watkins and others.

The coal bearing formation, as far as at present indicated by prospecting, covers an area extending about 50 miles in a north-westerly and south-easterly direction, with a width of about 30 miles. Over a large portion of this area the present of coal has been shown by prospecting, but serious attempt at development has been made only in the southern end of the field, where the early discoveries were made. This exploration, as it happens, has been done where the seams are most severely crumpled, folded and eroded. There has been nothing beyond handwork, consisting of tunnelling and shallow inclines. It is believed that diamond drilling will prove better seams than any that yet have had attention. At one time some 600 square miles of coal leases were held in this field but since then have reverted to the government.

Of the many seams located a number have been more or less prospected by tunnelling. They vary in thickness from 3 to 8 feet, with possibly some thicker, and are composed of layers of coal and shale. These layers of coal vary from 6 to 24 inches in theikness, while the shale partings vary from $\frac{1}{4}$ to 4 inches in thickness. Many of the seams, as stated, are twisted and crumpled, with poor roof and floor for mining, but there are a number in which the conditions are good for commercial mining. Speaking generally there are many seams in the field which are large enough to admit of easy mining. Without more reliable and extensive development no reliable estimate can be made as to tonnage.

As to quality the seams exposed are rather "dirty" and will run high in ash. A considerable part of the coal carries a high percentage of shale which it will be difficult to remove by washing. Then, too, what has been developed has been found much shattered and the cleavage planes are filled with foreign matter, such as quartz, calcite etc. It is to be remem-

bered that these observations have to do with the seams on which development, little as it is, has been done.

The coal of the field has been classified as anthracite, although some of it is more nearly described as semi-anthracite. It is an excellent coal. Some samples, however, run high in ash, and others go as low as from 5 to 10 per cent. in ash. One report by a reliable authority places the ash content at about 6 per cent. These are very promising seams. This is a splendid domestic fuel and no doubt would be able to successfully compete for the markets of the Prairies and northern British Columbia. Prospecting on a large scale by diamond drilling, however, is necessary to demonstrate the commercial possibilities of the field because little or nothing is known as yet regarding the undisturbed portions of the field.

Coal Measures on Copper River.— There are promising coal measures on Copper River, some forty miles from Telkwa, Grand Trunk Pacific Ry., a considerable portion of which is controlled by the National Finance Co., Vancouver, in liquidation, through the administrators, the Yorshire Canadian Trust Co., of the same City. There has been some exploratory work done here during the past summer, three or four diamond-drill holes having been sunk. The results of this work have not been announced but are understood to have been satisfactory.

Miners Advocate Amendment to Act.— A deputation of coal miners, representative of the coal mining district of Nanaimo and Ladysmith, Vancouver Island, recently interviewed Hon. A. M. Manson, Attorney General, and Hon. Wm. Sloan, Minister of Mines, seeking an amendment to the Workmen's Compensation Act making the disease Nystagmus compensable under the Act. The miners maintain that Nystagmus is prevalent among the coal miners of this Province, that there have been instances where those afflicted have been unable to continue work, and that there are many slightly affected without realizing their trouble. They argue that it is simple justice to give those so suffering the benefits of protection afforded by the legislation in question. The Ministers promised that their petition would be given every consideration.

Mine Accidents.— There have been a number of minor accidents in the coal mines of Vanvouver Island during the past few weeks. A miner was suffocated in the Cassidy Mine, Granby Consolidated Mining & Smelting Co., when he entered a "fenced off" place. Two men were killed, one being a fire-boss, in the Wakesiah Mine, Western Fuel Corporation of Canada, by a small explosion, practically no injury being done to the mine. These followed in the wake of other accidents in which men either lost their lives or were injured. Mr. George Wilkinson, former Chief Inspector of Mines, has been given a special commission to make the fullest inquiry into each of these occurrences.

Good Coal in Nicola-Princeton Field.— The Carbondale Coal Co. is making satisfactory progress in the development of its holdings in the Nicola-Princeton field. A shaft has been sunk one hundred feet and the seam is being opened up to permit the use of a shearing machine. The coal already has found a market in Princeton and adjacent communities and is said to make an excellent domestic fuel.

It has been demonstrated by exploration that a considerable quantity of cassiterite is available in alluvial deposits in the Katanga district of Belgian Congo, which has become prominent lately as a producer of copper. An appreciable amount of tinstone has already been recovered and shipped.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eigth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings, full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invitedto write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

EDITORIAL

I am in hopes that in the peat bogs of Ontario and Quebec and other portions of Canada, we have what will yet be a most important asset.
Thos. W. Gibson—1904

MILLIONS OF TONS OF PEAT FUEL NOW AVAILABLE

The coal statistics of Canada for August, issued last week by the Dominion Bureau of Statities, are a vivid reminder of the salient fact of Canada's fuel problem. In spite of the interference with output due to the strikes in Alberta and Nova Scotia, the cumulative production throughout Canada for the first eight months of the year was 7,745,000 tons, as against 9,319,000 tons average for a similar period in the three preceding years.

During August, 29,000 tons of anthracite, 6 per cent. of the usual amount for that month, was imported. Bituminous coal to the extent of 364,000 tons, or 21 per cent. of the normal amount, was brought in, 305,000 tons of it into Ontario and 50,000 tons into Quebec. The scarcity of fuel indicated by these figures would not now be alleviated as much as it is, were it not for the fact that the railways of the United States that bring coal to Canada control also some of the coal mines, and have taken care to get promptly the extra profit due to the long haul to our borders.

Most of the householders in urban communities throughout Ontario and the western part of Quebec must realize clearly now, their present utter dependence upon coal produced in a foreign country. Consequently now, as never before, there is an opportunity to introduce the use of Canadian fuel wherever it is commercially feasible. The new fuel committee in Ottawa has a shrewd eye to this opportunity and will, no doubt, take full advantage of it.

Today we wish to point out a resource in fuel that now seems to be, for the first time, available for commercial use in Canada. Elsewhere in this issue there is a description of the resources of potential peat fuel contained in the comparatively few peat bogs that have been surveyed up to the present. There are literally millions of tons of fuel available within reach of almost every large centre of population in Ontario and Quebec, while the supply of the smaller communities from this source is assured for an indefinite period. Luckily, the further north one goes from the Pennsylvania coal fields, the more peat there is available, though few of the bogs have been surveyed as yet in the northern parts.

The work of the Joint Peat Committee of the governments at Toronto and Ottawa during the past four years has resulted in the invention of mechanisms, in the main automatic, that will turn raw peat into a first-rate fuel at such low cost that the process is almost certainly capable of commercial application. Due to motives of economy, the central part of the machinery used during the season of 1922 at the Alfred bog was not renewed to include the advances in design indicated as expedient during the previous season. As a result of this, and of further improvements in design indicated during the season just closed, it has been shown that much greater economy of operation than that actually accomplished can be reached with a new plant. Nevertheless the experiment has been, on the whole, very successful. During the four seasons of experiment, there has been developed effective machinery much more complicated than the steam locomotive, which has reached its present state of effectiveness only after a century of continuous effort. The development of the Anrep-Moore machine peat manufacturing plant will, no doubt, be continued until it is even more effective than at present.

The immediate problem that confronts those interested in peat is how to ensure the continuance of the good work. The Ontario government has withdrawn its support, deeming the present results sufficient to warrant private capital investing in a commercial peat manufacturing plant. This private investment is not yet assured. Meantime the Prime Minister of Quebec has intimated publicly that his government has now an active interest in peat. As Quebec has not yet contributed its share to this common cause, the present time might prove most opportune and effective for financial aid that would be of comparatively slight dimensions compared with the sums already contributed.

The peat experiments have met with such a marked degree of practical success that there is now warranted a thoroughgoing commercial trial of the process. Whether this should be financed from public funds or should be undertaken privately, we are not prepared to say. But it would be calamitous were ultimate success jeopardised by a discontinuance of the present annual progress. Such a mistake was made 14 years ago, when a change of government interrupted the progress of a promising investigation into the use of

peat, which is only now being brought to fruition after years of lost time. We must have the use of these millions of tons of peat fuel.

TIMIDITY AND TEMERITY

Rejection of a mine or prospect is easier than acceptance for the mining engineer who examines it. His responsibility seems to end when he turns down a property; and to begin only when he reports favorably upon it.

We have often wondered just how far the mining engineer is influenced by this consideration. How often are properties reported upon adversely chiefly because the engineer does not care to assume the responsibility of recommending them? To what extent does sheer lack of moral courage, the fear of risking a reputation, or positive inability to size up the merits of prospects or mines, limit the usefulness of examining engineers? We shall not attempt to answer that question. But there is something to be said regarding the fact that mining engineers, as a class, have acquired the reputation of being less willing to recommend than to damn a mining property. It is a matter of personal opinion as to whether this is or is not fair to the engineer. But there can be no question of the fact that the reputation sticks. Prospectors and investors make the same complaint.

There is a very simple corrective which, once applied, will protect the engineer from injustice. If, in all instances when mining properties are examined for purchase or sale, the examining engineer were to make a straight-forward, complete, and readable report to his employers, a report containing a resumé of his reasons for or against purchase, couched in language that the layman can understand, then almost all the difficulties that surround such work would be removed.

We are moved to write thus by reason of the fact that we have read, with pain, some dozens of reports that might mean anything and generally meant nothing, or else presented conclusions without adducing adequate reasons.

Putting it by and large, the average mining report is not a document of which to be proud. It usually lacks precision of diction altogether. It dwells on non-essentials. It conveys no meaning to the layman. It neither satisfies the business man nor convinces the technical man. The very cloudiness of its meaning is taken as symptomatic of timidity on the part of the engineer.

The man who sets forth his opinions, or his convictions, in positive terms is to be preferred to him who hides his meaning under a cloud of words.

Moreover, an engineer's responsibility does not always end when he reports adversely on prospect or mine. His action, if ill-considered, may do irreparable hurt to a new camp. It may work a gross injustice upon a deserving enterprise. A man should be very sure of his ground before he exercises this, the most important of his professional functions.

FELDSPAR FOR GREAT BRITAIN

The results of special investigations conducted by Mr. H. S. Spence in Great Britain seem to indicate that there is not much chance for developing a market for Canadian feldspar in the old country. As reported in the press, Mr. Spence bases his discouraging statements upon the costs of rail and ocean transportation as against the comparatively low price obtainable for crude feldspar in Great Britain, as well as upon the prevalent use there of "Cornish stone" instead of feldspar, this stone being a natural mixture of feldspar, China clay and quartz. In this he is patently right.

However, we would like to learn Mr. Spence's opinion of the commercial practicability of selling ground and carefully graded Canadian feldspar in the English market. Frankly, we do not think that any reasonable person would contemplate shipping crude feldspar across the Atlantic. Hence Mr. Spence's reported opinion has no particular bearing on the case. Also, his quoted statement, to the effect that the annual consumption of feldspar in England by all trades amounts to but five thousand tons, is obviously a statement only of present conditions, and ignores the possibility of modifying these conditions. It is quite possible that the use of Canadian feldspar might be a decided advantage to English potters.

We invite, therefore, a full and authoritative pronouncement on the possibilities of developing an overseas trade in prepared feldspar. Information from private sources leads us to believe that Mr. Spence may be taking too gloomy a view of the situation. However, as Mr. Spence is an experienced and competent official, it is more likely that his commission in making this investigation and report did not include a study of possible future developments dependent upon such private initiative as would be required to put Canadian feldspar on the British market.

PROSPECTIVE GUSHERS FOR ONTARIO!

We have before us a prospectus and a booklet from an oil company that are of unusual interest. In the first place they do not come from Fort Worth, Texas —that prolific source of oil promotion whose output (of circulars) has inundated the Canadian mails of late. No — this is a home-grown, Canadian product—strictly Made-in-Canada.

The booklet discloses some very interesting information. In prehistoric times a Great Arctic Oil River meandered down through North America from Mackenzie River to the Gulf of Mexico. Where lake expansions occurred on its serpentine course, there now

are great basins of oil. One of the greatest of these lakes lies conveniently located beneath Mariposa township, near Peterborough, Ontario. Here (we are told by the anonymous author of this interesting document, who claims exclusive scientific knowledge in the matter) lies untold liquid wealth. Some enterprising citizens of Peterborough have, therefore, incorporated the Central Ontario Oilfields, Limited, and are offering stock for sale for the purely nominal price of $2 a share.

We have no more space to quote the startling scientific information included in these interesting documents. We fail to notice, however, that the necessary statutory information has been included, and wonder if these magnanimous members of the directorate of Central Ontario Oilfields, Limited, are liable to action under the existing laws. It will be a pity if they are not. Provincial Secretary, please take notice.

BAUXITE, FELDSPAR AND ALUMINIUM

On another page Mr. Kirby Thomas describes briefly a deposit of bauxite, of unusual dimensions and purity, that has been developed in British Guiana by American capital. It is good news that a British colony contains what is now proved to be one of the best available sources of aluminium ore, and it is satisfactory to have it developed. It is a pity, though, that Britishers are not to reap the full benefit of its possession.

The United States is at present the world's principal producer of aluminium. She has assumed this leading position by virtue of cheap hydro-electric power and bauxite deposits, conveniently located in the southern states, principally in Arkansas. During 1921, 140,000 tons of bauxite was mined and 20,000 tons of the metal, worth $11,000,000, produced in the United States these totals being only one-half to one-quarter of the totals of the years immediately preceding. The exhaustion of the best deposits available in the United States has induced the aluminium manufacturers of the United States (virtually one corporation) to look for supplies elsewhere; hence their activity in British Guiana.

Canada has more, and cheaper, hydro-electric power than the United States, and it is, in general, more conveniently located. Already there is a large amount of aluminium made in Canada, and the amount is bound to increase very rapidly. At present the material for this is brought from St. Louis as refined alumina, the bauxite having been treated there. If any considerable part of the alumina to be used in Canada should originate in British Guiana, this route to, say, Shawinigan Falls via St. Louis will be roundabout. It will be more logical, and possibly more economical to refine the bauxite in Canada.

During the past week definite announcement has been made in the Quebec legislature of the development of the huge water-power at the Grande Decharge, where the Saguenay River issues from Lake St. John. The problem will be to make effective use of this power. One wonders whether part of the plan may not include a new aluminium plant, to use alumina refined in Canada from British Guiana bauxite. This would prove a very acceptable addition to Canada's metallurgical equipment, until such time as our own resources in alumina, still securely locked up in our vast deposits of feldspar, shall have been made available through the researcher's art, and a completely indigenous aluminium industry thus established.

EDITORIAL NOTES

The destruction by fire of the East Broughton mill of Asbestos Mines, Limited, is unfortunate at this time. This mill produced the short fibre characteristic of the East Broughton area, for which there is at present a very active demand. The Company's mill at Black Lake produces mainly high-grade fibre, for which an active demand is only commencing again. The management of this company is, however, very energetic and in an unusually strong financial position so that whatever may be the insurance on the old plant (this has not yet been publicly announced), it is certain that Quebec's asbestos industry will not long lack the support of this important producer.

General Smart has advocated publicly in the Quebec legislature the use of peat as fuel, as well as its use for the production of coke, oil and gas by distillation. This is good news. It is also very satisfactory to know that the Quebec government is ready to pay a royalty on the production of peat fuel. Hon. M. Perrault's rather pessimistic remarks, coupled with this announcement, can be discounted in view of the known success to date of the experiments at Alfred, Ontario.

In commenting recently on progress at the Pancake Lake property of the Crown Reserve Mining Company, we stated, erroneously, that Mr. Harry Ke[illegible] [illegible] charge. It is Mr. H. J. Stewart who is conducting the operations on this property.

PEAT

Vicissitude was sure thy middle name,
O, fibrous fuel!
Long, very long, hast thou had [illegible]
And treatment cruel!
But now the people who have [illegible],
Into their coal bins eagerly have [illegible],
And in their furnaces with vigour [illegible]
Thou moss-born jewel!

ANON.

Editor's Note: Peat [illegible]. It is significant that it is now [illegible]. It is more significant that our hired [illegible] as a subject for his [illegible]. He [illegible] popular acclaim: he follows the crowd.

The 1922 Peat Experiments

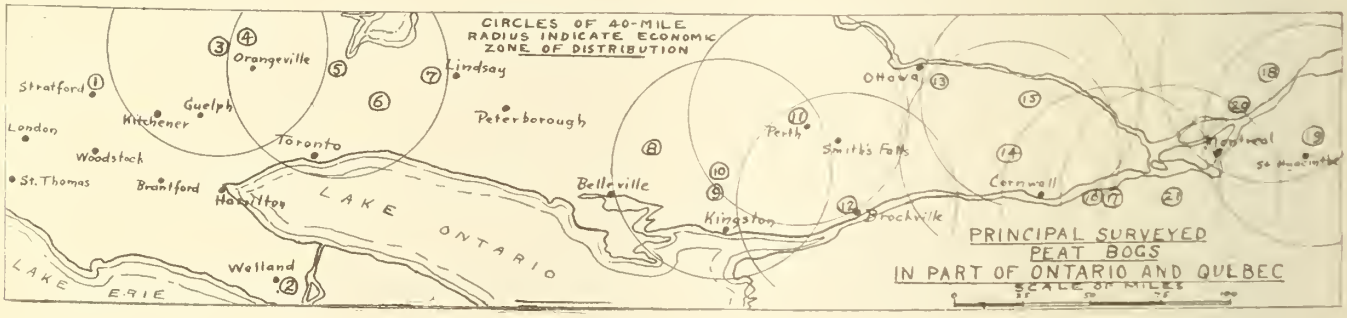
SOME RESULTS FROM OPERATIONS AT THE PEAT BOG AT ALFRED, ONTARIO

Few Canadians realize the extent and the potential value of the fuel now lying unused in the peat bogs that lie scattered from coast to coast. It is not likely that these will be put to use within a measurable space of time in those parts of the Dominion where Canadian coal is available; but in Ontario and in the western part of Quebec, which are dependent at present on imported fuel, the possible utility of the peat bogs may well be examined with the greatest care.

During the past season two articles in the *Canadian Mining Journal* have dealt with the manufacture of peat. The first, on March 31st, discussed the relation of peat to the other fuels, with the conclusion that it is at present useful primarily as a domestic fuel, and a very good one at that. On August 4th a description was given of the experimental operations conducted during the summer on the bog at Alfred, Ontario, which have resulted in the manufacture of 5,000 tons of excellent fuel. The present article will give some results observed during the work of the past season, and deductions that bear on the commercial application of the Anrep-Moore Machine Peat Manufacturing Plant. But first it will be well to examine briefly the extent of the natural resource it is hoped to put to use by this means.

Surveyed Peat Bogs

Since 1908, when at the instance of Dr. Eugene Haanel, the Mines Branch, Ottawa, first undertook the investigation of peat as a source of fuel, a peat expert has been employed each summer to examine the bogs available. Those near large centres of fuel consumption, and near a railway as well, have been examined first. The plan and table below give data regarding a number of these, selected from among those surveyed because of their favourable location. A railway already crosses or touches most of these, and all are within reach of cities and towns that are now importing coal to the extent of millions of tons annually, in the aggregate, a large part of which could be replaced by peat fuel. The surveying of peat bogs has been merely commenced, and when those that are at present less accessible or remote from large centres of population shall have been surveyed, the total will be a vast amount, comparable with the coal beds that are now being drawn upon to provide us with fuel. Seven bogs now surveyed within a convenient distance of Toronto are capable of producing 26,500,000 tons of fuel. Seven bogs in the Montreal district could furnish 23,500,000 tons of fuel.



No. on Plan	Name of Bog	Location	Fuel Available Tons as prep.	Calorific Val. B.T.U. per lb
1.	Brunner	1 mile from Victoria Road, Station G. T. R.	1,172,000	8,850
2.	Welland	6 miles from Welland, on Welland Canal.	4,106,000	8,667
3.	Luther	2½ miles from C.P.R., near Grand Valley, Dufferin County.	7,443,000	8,364
4.	Amaranth	4 miles from Crombie Station, Dufferin County.	264,000	8,710
5.	Holland	6 miles from Newmarket, on G. T. R.	8,219,000	8,510
6.	Marsh Hill	1 mile east of Uxbridge, on G. T. R.	9,620,000	8,068
7.	Manilla	2 miles from Mariposa Station, Ontario County, and ½ mile from G. T. R.	399,000	8,100
8.	Stoco	½ mile from Stoco Sta., C.N.R., Hastings County.	1,345,000	7,557
9.	Harrowsmith	On C.N.R. and C.P.R., Frontenac County.	396,000	. . .
10.	Verona	On C.N.R. and C.P.R., Frontenac County.	10,636,000	. . .
11.	Perth	1½ miles from Perth, on C.P.R.	5,126,000	9,148
12.	Brockville	3 miles from Brockville, on C.P.R.	1,694,000	8,173
13.	Mer Bleue	8 miles from Ottawa on C.P.R. and G.T.R.	5,125,000	9,126
14.	Newington	At Newington Station, on N. Y. C. Ry.	6,208,000	8,465
15.	Alfred	At Alfred Station, on C. P. R.	9,369,000	8,730
16.	Large Tea Field	On St. Lawrence River and G.T.R. near Valleyfield.	4,824,000	9,400
17.	Small Tea Field	On St. Lawrence River and G.T.R. near Valleyfield.	3,315,000	9,200
18.	Lanoraie	On C.P.R. at Lanoraie Sta., 40 miles from Montreal.	4,751,000	8,967
19.	St. Hyacinthe	On C.P.R. 2 miles from St. Hyacinthe Station.	3,666,000	8,850
20.	L'Assomption	2 miles from L'Epiphanie Sta., L'Assomption County.	1,760,000	9,700
21.	St. Isidore	3 miles south of St. Isidore Station.	2,242,000	8,900

A Commercial Method now Available

The question is, how to put to commercial use these stores of potential fuel. Air-dried peat is used in country districts in Ireland and Scotland and on the Continent; but no one would use such an inferior fuel in Canada. Machine peat is made successfully in Sweden and Germany; but the processes of manufacture in use there are much too costly for successful use in Canada. The experimental work of the Joint Peat Committee during the past four years has provided the answer to the question. The Anrep-Moore Machine Peat Manufacturing Plant, developed slowly, bit by bit, during these four years, is now capable of making fuel at a cost that will allow it to compete with coal, if one can judge by the actual results and logical deductions from these results.

The evolution of the various elements of this plant has been an extremely interesting process to watch. The principle used in excavating was laid down first by the late Mr. S. Anrep of Helsingburg, Sweden, whose son, Mr. A. Anrep has worked on the peat surveying for the Department of Mines, Ottawa for a number of years. Mr. E. V. Moore, engineer for the Joint Peat Committee, adapted Mr. Anrep's idea to practical use. The remaining two essentials in preparing the raw peat are first, maceration, to break down the cell walls and so let the water run away and evaporate, and second, spreading the resulting pulp on the bog. After trying out a number of specially designed macerators, Mr. Moore has found that a standard swing hammer mill serves the purpose best of all. For spreading the peat on the bog there has been devised a simple and very clever bit of mechanism that has been described briefly in a former article. Additional ingenuity has been required to construct a number of additional mechanisms to aid in harvesting and stock-piling the dried peat and loading it into railway cars.

Cost of Production, 1922

During periods of normal operation in the season of 1922 (including a reasonable percentage of lost time) observation shows the production cost per ton of fuel made was about $3.50 made up approximately as follows:

Raw material (royalty)	$ .05
Power	1.10
Labour, oil and repairs for manufacturing	.65
Loading and coiling	.25
Harvesting	1.10
Clearing and draining bog	.05
Miscellaneous charges	.30
	$3.50

Power was derived from peat, and this has been charged up at the rate it was sold to the public—$5.00 a ton. The labour charge includes the crew necessary to operate the machinery and keep it in order, and competent supervision of the mechanical operation. The turning of the blocks of half dried peat to expose the under side is done best by hand, and at the same time peat that lies in a depression that has retarded drying is piled in open heaps (cubing). The harvesting includes loading the dry peat by hand on a travelling belt that delivers it into 1½ ton cars, the laying of the narrow gauge tracks on which these cars run, hauling to the railway, stock piling, and loading into railway cars. The time lost in turning round the whole apparatus when it reaches the end of the long excavation, in preparation for the return trip along the other side, is included.

To this operating charge must be added a charge for overhead expenses. The replacement cost of the whole plant (which would manufacture 20,000 tons of fuel during the season of 100 days if worked 20 hours a day) is approximately $90,000. A fair charge for depreciation and interest is 20 per cent. per annum, which is $18,000. The annual turn-over (20,000 tons at $5.00) is $100,000; a charge of 10 per cent. against this for administration and office expense will cover its cost amply—$10,000 a year. This makes a total overhead expense of $28,000 a year, or $1.40 a ton. Add to this the manufacturing cost of $3.50 a ton and the total expense is $4.90 a ton. Thus the plant in use during the season of 1922, imperfect though it is, has about cleared expenses selling at $5.00 a ton. It must be borne in mind, of course, that only the charges to which a commercial operation would be put are included in this total; the cost of the experimental work itself is a separate item.

Alterations to Effect Economies

As mentioned above, the plant at Alfred has been developed, bit by bit, during the progress of four years of experimental work. Thus it is, inevitably, far from perfect in its construction as every experimental plant must be. However, the spreading, harvesting, storage and loading equipment, are in sufficiently good shape to warrant their inclusion in an operating commercial plant. A larger size of macerator will be required and two other parts need complete replacement—the excavator and the main power unit. The excavator was pieced together from pre-existing experimental machines, and has passed its usefulness. The steam plant at present in use does not deliver enough power, is weighty and cumbrous, and can best be replaced by electric motors driven from a separate generator unit. With the addition of these new items and minor alterations in the rest of the apparatus, the Anrep Moore Machine Peat Manufacturing Plant now at Alfred promises to make fuel on a commercial basis.

This suggested alteration of the existing plant would effect very considerable economies in the present cost. The present charge of $1.10 per ton for power, for instance, would be cut to about 26 cents per ton, as follows:

Cost of Steam Power, Season of 1922

Fuel, 9 1/3 tons at $5.00	$46.67
Labour, 1 men	17.00
Gasoline	3.80
Oil and supplies	5.50
Repairs	5.00
Total, 100 to 7 tons	$82.97
or, per ton, say	$ 1.10

(Note—Average capacity 100 tons per 10 hours.)

Diesel Engine, Electric Generator (3 Motor Compressed Plant)

Fuel (100 gallons)	$ 15.00
Labour, 1 man	5.00
Oil and Supplies	1.00
Repairs	1.00
Total, for 100 tons one shift	$22.00
or, per ton	$ 0.26

Again, a slight change in the harvesting mechanism will reduce the cost from $1.10 per ton to 85 cents. With the mechanism brought up to date in these particulars, it is confidently expected that the costs will fall within the following limits:

Raw material (royalty) (as before)	$ .05
Power (Diesel)	.26
Labour, oil and repairs (for manufacturing)	.30
Turning and cubing (as before)	.25
Harvesting	.85
Moving round ends of excavation	.10
Clearing and draining bog (as before)	.05
Miscellaneous charges	.14
	$2.00
Overhead charges (as before)	$1.40
Total cost, per ton	$3.40

Thus it is probable that the cost of production, which was $4.90 this year, can be reduced to $3.40 per ton or less by effecting the changes in the mechanisms that the experimental work of 1922 has shown to be expedient. These changes are not radical or dependent upon experiment, nor do they make the replacement charge of the plant greater than at present. What they will do is to make possible a reasonable profit, say $1.50 a ton, in the manufacture of the peat fuel when sold at $5.00 a ton at the bog.

Quality of the 1922 *Peat Crop*

Never before has machine peat been made in Canada to equal that produced at the bog in Alfred during the experiments of the past summer. In spite of the vicissitudes that are bound to accompany experimental work, the 5,000 tons of peat fuel produced and sold was of a uniformly high quality. It found a ready sale as far west as Peterborough and Toronto, as far north as Liskeard, and as far east as Montreal. There are now several hundreds of householders convinced, from practical trial, that machine peat is an ideal fuel for cook-stoves and open grates, and that it can usefully replace the more expensive anthracite fuel in the furnace in mild autumn weather. If the Peat Committee had manufactured several times the amount of peat made available from the experiments, it would have found a ready sale.

* * *

Throughout the four years of the Joint Peat Committee's investigations, the Committee and their engineers have laboured most faithfully to accomplish their end. They have been hampered by the inherent disabilities of governmental control and direction, and especially by the uncertainty, from year to year, of a continuance of the vote of money to carry on their work. That they have carried on the work in spite of difficulty and discouragement speaks volumes for their determination and persistence. That they have now brought in sight the goal they set out for originally, is a tribute to their mechanical ability and ingenuity as well as to their perseverance and their faith in the ultimate outcome. The path of the pioneer in any line is a rugged one, and his reward is not always sure. The work instituted by Dr. Haanel years ago and his persistent efforts since then on behalf of a peat industry have been ably continued by engineers of the next generation. The Peat Committee and its staff have earned the hearty thanks of Canadians in general, and they deserve continued encouragement and financial support, if not from public, then from private sources.

NEW MAPS READY

The Ontario Department of Mines has already off the press one of its 1922 geological maps of Northern Ontario—a most expeditious performance, and well worthy of this most excellently managed public department. This map sheet, the *Blanche River Area,* is five townships (30 miles) square and extends from the northern end of Lake Temiskaming up to the townships of Catherine and Skead, and from the interprovincial boundary westward to the townships of Tudhope and Truax, which are included in the Elk Lake-Montreal River sheet of 1907. The Boston-Skead area to the north was mapped in detail in 1921 and described by Messrs. Burrows and Hopkins in their recent report. The new map thus fills in the gap between the Cobalt sheet and the most southerly of the gold areas. It will accompany a report by Messrs. Burrows and Hopkins in Volume 31, Part 3, 1922.

The Blanche River area is covered mainly by the subsidiary clay belt that extends southward as far as New Liskeard. The roads, post-offices and schools shown on the map indicate the extensive settlement of this fertile land that has been induced by the presence of the railway and of the surrounding mining communities. Only derelict mining camps are to be found within the area itself —Casey, Wedigo, Cane and Triangle.

With the mapping of this area, and of some townships to the north that will be included in the forthcoming Kirkland map, there now remain few blank spaces in the general geological map from the Canadian Pacific main line northward to the Transcontinental Railway over a width of a hundred miles westward from the interprovincial boundary. The work of mapping in detail this area of close on 18,000 square miles has been divided between the Ontario Department of Mines and the Geological Survey at Ottawa. It represents a huge task, and it has been well done. A new map on the scale of six miles to the inch to replace that published in 1913, is projected for the near future.

MONTREAL BRANCH MEETING OF INSTITUTE

The Montreal Branch of the Canadian Institute of Mining and Metallurgy met in the Windsor Hotel, Montreal, on December 8th, to hear an address, illustrated by moving picture, on the new "road-rail" method of transport by Mr. Herbert Kennedy, and to make nominations for the 1923 election of officers for the Institute. Mr. John Dresser was duly nominated for the presidency, and Prof. J. W. Bell and Mr. T. C. Denis as councillors. The secretary was directed to forward a request to the Thetford Branch of the Institute that they make a nomination or nominations for councillor.

Mr. Kennedy described clearly the operation of the "road-rail" transport system, which was developed in central Africa during the war-time, and whose commercial application is sponsored by William Beardmore and Co., the well-known Scottish shipbuilders and engineers. It may well be that this new system will prove useful in opening up Canadian mining camps.

A CORRECTION

A correspondent in Rome draws attention to the fact that in reviewing the Imperial Mineral Resources Bureau's volume on *Quicksilver* recently we stated erroneously that Monte Amiata was formerly in Austria. It is the other mercury-producing district, Idria, that was in Austria.

Letters From Porcupine--V

THE PERSEVERANCE OF THE—SAINTS

Looking back over the slowly unfolding panorama of Porcupine's history affords an interesting study in the survival of the fittest.

To avoid unseemly personalities it is expedient to make one or two composite pictures. Each will be true to life generally and particularly, but none will be distinguishable as the presentment of any one person's career.

* * *

Z., along with a few friends, got hold of a "veteran" claim shortly after the first stir in Porcupine. With some difficulty he financed the purchase of the claim and the formation and flotation of an operating company. The geology of the camp was little understood and a great deal misinterpreted. The vein on which the first shaft was sunk was very spotty, alternately rich and lean. When it was lean it was very lean indeed, and when it was rich it was rich enough to warp anybody's judgment. The lean ore, of course, predominated. Z. had that blind faith in the property that makes a man hold on.

After two re-organizations the company was so hard pressed that control was sold to a group of United States financial men. Meanwhile Z. had been forced to fight two or more commission suits instituted by persons who had no real claim on him whatever.

Z lost the property. Three years of the hardest kind of work had gone for nothing. However, emulating Henley's hero, he refused to bow to the buffetings of fate. Patiently, and with never a thought of surrender, he picked up other properties. Gradually he secured competent backing. In every move he was handicaped by the tactics of parasites who wished to be bought off, and by disparagers who hated to see him succeed—strange freaks of human nature. It took him somewhat over four years to get going. He is arriving.

* * *

Quite different is the story of X., and X. was a radically different person. He was a promotor first, last and always. His intention in securing a Porcupine property was to make it the *raison d'etre* of a stock-jobbing campaign in the course of which he would clean up and get out from under. So far as shareholders were concerned, they could be "damned". Nor did the mine interest him except as an excuse for gonging the public. His intimates were told as much.

X. was in a fair way to accomplish his purpose. Unfortunately for him he was too greedy. He tried to enlarge his haul by multiplying the capitalization of his company. At this stage the newspapers began to criticise him. It became unsafe for him to carry out his plan. So he arranged to have good news sent by wire from the mine at judicious intervals and kept on financing it. Meanwhile, much to his surprise, the mine began to show some ore. But he had already so juggled with the company's shares that outside aid was imperative. His top heavy organization was again remodelled—closer to his heart's desire, so to say. In London he succeeded in loosening the strings of some cornucopian purses. London may have a run for its money; but it will assuredly not be X.'s fault if it does. Yet X.'s kind seem to appeal to the Old Country magnate.

The sporting spirit of Z. is a pleasing contrast to the avariciousness of X. The former played the game straight and could profit only if his associates profited. The latter would, and did, get his slice no matter what happened.

* * *

A third composite portrait is that of Y. who has been operating for some little time and very strictly minding his own business. In developing his mine he is using privately subscribed funds, which are most carefully administered and applied to the development of the mine solely. Y. has sought no publicity and has done no talking—a fact that is resented by sundry inquisitive persons. Here, again, is a side-light on a strange quirk in human psychology.

The plant on Y.'s property is efficient and unpretentious. He is doing his best to make certain of a large reserve of ore before he begins building a mill. He has spent more time in this fundamentally necessary work than X. would require to "put across" a dozen dizzy schemes.

* * *

W. is a vendor of claims. In every mining district of Northern Ontario he has staked claims, done the assesment work, and disposed of some of them at good, fat prices. He knows his way about, and is of the David Harum school of bargainers. In slack times he can turn his hand to many things and make more than a living. Pulpwood and cord-wood contracts are sources of incidental earned increment to him. But his real vocation is selling undeveloped claims.

Probably he would fail lamentably in any attempt to put his geological ideas down on paper. Nevertheless, he thinks clearly and to the point when he is diagnosing new ground. He uses geological maps and needs more of them and more details than he can get from published maps. He is a shrewd, quiet, and enterprising citizen who is a genuine asset to the community. It is this class of man that needs and deserves special attention from the Ontario Department of Mines.

* * *

In closing this very casual series of Letters from Porcupine I wish to emphasize one point. That is, that all investors, or would be investors, in gold mining shares should visit Porcupine. It is eminently worth while for the Canadian business man to see for himself what has been done and what is being done in an industry that is to become the economic stabilizer of the nation.

J. C. MURRAY

The government of New Zealand has undertaken to expend a million pounds a year for the next ten years on the development of hydro-electric power. There is additional power being developed constantly by private capital.

On the property of the Transvaal Silver and Base Metals company, southeast of Pretoria, South Africa, silver-lead occurs in a siderite gangue in diabase intrusive sheets of comparatively recent origin. The ore is desulphurized and smelted in blast furnaces at the mine, and the pig lead shipped to Europe for refining and desilverizing, there being about 100 ounces of silver to the ton of lead.

The Sulphur Industry of the U.S.

By ALBERT G. WOLF, Mining Engineer, Texas Gulf Sulphur Company, Gulf, Texas

The world's consumption of sulphur in the elemental state is greater than is generally realized. In the United States and Canada alone this amounts to three-quarters of a million long tons annually. Practically all of this, over ninety-nine per cent. is supplied by three mines on the Mexican Gulf Coast of the United States. These same mines export annually approximately one-quarter million tons to European countries. These mines are: The Texas Gulf Sulphur Company, Gulf, Matagorda County, Texas; the Union Sulphur Company, Sulphur, Calcasieu Parish, Louisiana; and the Freeport Sulphur Company, Freeport, Brazoria County, Texas.

Sulphur mines, like metal mines, may be classified as high-cost and low-cost producers. Adopting this classification, it can be safety stated that the Texas Gulf Sulphur Company and the Union Sulphur Company are very low-cost producers, whereas the Freeport Sulphur Company is a relatively high-cost producer. All three of these mines, however, are in a low-cost class by themselves as compared with European and Asiatic mines, and the few small-tonnage producers of the United States not mentioned above.

Salt Dome Formations

The coastal sulphur deposits occur in what are known as salt domes. These are true structural domes that are usually, although not always, indicated upon the surface by slight topographic domes in the low, flat coastal plain. These interesting formations are scattered over a belt extending about seventy-five miles inland from the coast and reaching from the Atchafalaya River, in Louisiana, to the Colorado River of Texas. There are fifty or sixty domes, many of them being productive of oil, but to date only four have been found to contain sulphur in commercial quantity.

The structural features of these domes may be divided, for our discussion here, into three parts, the salt core, the cap rock, and the overlying and abutting sediments. Almost all of the sediments are unconsolidated, consisting of gumbo, sands, clays, and beds of marine shells, with lenses of limestone and sandy limestone. The upper strata are of the Quaternary, and the lower of the Tertiary. The deeper strata have been broken through, by the intrusion of the salt core, and bent upward at angles of thirty degrees to almost vertical, and the overlying strata have been gently arched by the upthrust.

The core consists of a mass of rock salt, more or less circular or elliptical in horizontal cross section, with radii varying from one-eight to one mile in different domes. Its top slopes from the center in all directions, gently near the center, and then increasingly steeper, giving the entire core somewhat the shape of a paraboloid slightly flattened at the top. The depth to which a salt core extends has never been determined. Several wells have been drilled two thousand feet in salt, and one case is recorded where a well penetrated three thousand feet of salt without passing through it.

The cap rock consists of anhydrite lying immediately over the salt, and above that, porous limestone and calcite. In this limestone occurs the native sulphur. The depth of the cap below the surface varies from a few feet in some domes to fifteen hundred feet or more in others.

Sulphur Mining

To extract sulphur from these salt-dome deposits there are required a competent drilling and field-operating organization and a boiler plant of large horsepower, together with water superheaters, high pressure pumps, and air compressors.

Holes are sunk to the bottom of the sulphur-bearing formation by the rotary method of oil-well drilling. In these holes four concentric strings of pipe are set. The first is an 8-in. or 10-in. casing to cap rock. Then a 6-in. line is run to the bottom of the sulphur stratum. This string is perforated near the bottom to permit the entrance of molten sulphur. The third pipe is 3-in. in size, and through it the sulphur is raised. Inside the 3-in. is a 1-in. line for compressed air.

Water, heated to about 325 deg. F., and at 100 to 250 lb. pressure, is pumped into the well between the 3-in. and 6-in. pipes, sometimes through the 3-in. also, and occasionally between the 6-in. pipe and the 8-in. casing. The sulphur is melted by the hot water and runs to the bottom of the well from where it is forced part way up the 3-in. pipe by the water pressure. It is raised the rest of the way to the surface by compressed air, under 500-lb. pressure, which is released from the 1-in. pipe near the bottom of the 3-in. pipe. The molten sulphur is then conducted through pipes to storage vats built of lumber. These vats are sometimes built to a height of fifty feet, and when finished contain anywhere from fifty thousand tons to one million tons in a single block. The sulphur is loaded from the vats to railroad cars by locomotive cranes and by car loaders.

The best idea of the mine-water heating plant can be obtained from a concrete example. In this case the plant of the Texas Gulf Sulphur Company is selected because it is the largest and most up-to-date installation. The major units consist of fourteen Stirling water-tube boilers of 702 hp. each, eight mine-water heaters, thirty-four duplex, slide-valve pressure-pumps, and six Laidlaw-Dunn-Gordon compressors. Half of the pumps supply water to the mine-water heaters, and the other half, called the "booster pumps", send the water to the wells under pressures up to 250 lb. when necessary. The boilers supply steam to the mine-water heaters and to the compressors, turbo-generators, and feed-water pumps. The heaters raise the temperature of the mine-water to approximately the temperature of live steam under 95 to 105 lb. pressure, say 325 to 335 deg. F. The plant, when designed, was expected to furnish sufficient hot water to mine one thousand tons of sulphur per day; as a matter of fact, about five times that amount has been mined when desired.

The Discovery of Coastal Sulphur

In 1865 oil seeps were found in Calcasieu Parish, Louisiana, and attempts were made to develop oil. This work led to the discovery of sulphur, in 1869, in what subsequently proved to be a salt dome, although at that time the nature of the deposit was not known. This sulphur deposit is now being mined by the Union Sulphur Company.

The first work was done by the Louisiana Petroleum & Coal Oil Co. Sulphur was found to occur in limestone at depth of five hundred to six hundred feet below the

surface, with a thick, overlying stratum of quick sand. The Calcasieu Sulphur & Mining Co. then acquired the property and attempted to sink a shaft by means of casing. This was a complete failure because of the immense quantity of water and the thick bed of quick sand encountered. In 1879 the Louisiana Sulphur & Mining Co. also tried to reach the deposit by shaft sinking, and failed in two different attempts.

Ten years later, the American Sulphur Company took up the work. A shaft was sunk to a depth of 250 ft. by means of a cylinder and shield, at which point the quick sand rushed in, filling the shaft and blowing everything out of the hole. Five men lost their lives in this attempt through asphyxiation by the poisonous gases rising from the sulphur zone. The American Sulphur Company then abandoned its work, after an expenditure fo $350,000.

Herman Frasch

This name will always be inseparably linked with the American Sulphur industry as that of the man who succeeded in making the great sulphur deposits of Texas and Louisiana commercially valuable, and who thereby gave to the United States domination of the sulphur markets of the world.

In 1891 Frasch became interested in the problem of working the deposit at Sulphur, Calcasieu Parish, Louisiana, and conceived the idea of melting the sulphur in place by means of superheated water, and pumping it to the surface in the liquid state. Subsequent tests proved the method, with certain modifications, to be mechanically successful, and all sulphur on the Gulf Coast is now mined by the method.

Before commencing operations, Frash obtained information from all of the companies which had tried to operate at Sulphur, but, unfortunately, most of it was misleading. Only the favorable aspects were set forth and the unfavorable ones concealed. The chief trouble was caused by a misconception of the nature of the deposit. As the sulphur was found in limestone, Frasch naturally believed the deposit to be similar to those of Sicily, and it would extend over a considerable area. Acting on this theory, he acquired some land within one and one half miles of the previous operations. Not until four barren wells had been sunk did he make the correct deduction that all the sulphur lay within the property of the American Sulphur Company. Acquiring this property, a drill hole was sunk, after much trouble, of sufficient size to fully determine the nature of the deposit. The first sulphur well was then drilled and equipped in a manner similar, in a general way, to all subsequent sulphur wells, except that a lift pump was used to elevate the molten sulphur. After "steaming" this well for twenty four hours, the pump was started, and the first liquid sulphur was pumped from the well. This occurred in January 1895.

Technically, the process was now a success, but not practically until the lift pump, which gave much trouble, had been replaced by an air lift, a device that had been previously used in many oil and water wells. After all these difficulties had been overcome, the process still faced commercial failure. The cost of heating the immense quantity of hot water required to melt the sulphur was prohibitive, as coal from Alabama, at a high price, was the only fuel available at that time. Some production, however, was made. During 1896 two or three thousand tons were extracted, and by 1898 a total of forty-five hundred tons.

In 1901, the fuel question was solved. That year Capt. A. F. Lucas proved his theory that the slight topographic elevation in Jefferson County, Texas, known as Spindle Top, overlay a structural dome and that the dome might be oil bearing. The discovery of this great oil field had two distinct effects on the future of the sulphur industry. It furnished an abundant and cheap supply of fuel, thereby insuring the commercial success of the Frasch process; and it lead to the drilling of a number of topographic domes in the Gulf Coast region, resulting in the discovery, in addition to many oil fields, of the other two sulphur deposits that are now being mined. These are Big Hill, the mine of the Texas Gulf Sulphur Company, and Bryan Mound, the mine of the Freeport Sulphur Company.

Following this discovery of cheap fuel, the Union Sulphur Company increased its production rapidly. The first notable output was made in 1903, when 23,715 long tons were extracted. From that time on the production increased until, in 1918, a maximum production for one year of 978,700 long tons was made; and a total production to the end of that year of over 6,000,000 long tons.

Freeport Sulphur Company

The next coastal sulphur deposit to be developed was Bryan Mound. As previously stated, the deposit was discovered in drilling for oil following the discovery at Spindle Top by Captain Lucas. Some further testing was done at Bryan Mound a few years later, and in 1911, Swenson & Sons acquired an option on the dome. This firm began the construction of a plant in Dec. 1911. The Freeport Sulphur Company was organized in July 1912, and in Sept. 1913 the holding company, called the Freeport Texas Company was incorporated. The first plant began producing April 18, 1912. Additional plants were built, making four in all with a total capacity of about 28,000 hp. The maximum yearly production by this company, a little over one-half million long tons, was made in 1917. All plants were closed down in 1921, on account of business depression, and remained closed until the summer of 1922.

Texas Gulf Sulphur Company

The dome in which the sulphur deposit of the Texas Gulf Sulphur Company occurs was originally known as Big Hill (the town that has been built at the mine by the Company is called Gulf). On the surface, Big Hill appears as a slight topographic eminence, rising to an extreme height of thirty seven feet above sea level and fifteen to twenty feet above the surrounding prairie. This topographic prominence induced the first development work following the Spindle Top boom. The area covered by the dome is several hundred acres. The cap rock is found at 850 ft. to 1000 ft. below the surface, and under an area three to four thousand feet in diameter. Systematic drilling has proved over ten million tons of sulphur.

The first well, drilling in 1902, blew in a tremendous "gasser". This created an excitement, many more wells were drilled, and an oil field of small size was opened. Big Hill continued as a producing oil field for three or four years, then the rapid encroachment of salt water and the discovery of better fields in the coastal region resulted in its total abandonment for several years. Sulphur was found in many wells during the period of oil well drilling, but the value of this discovery was not then recognized.

Messrs. Einstein and Harrison, who had done considerable drilling for sulphur at Big Hill, arranged in 1909 with Colonel Seeley, W. Mudd, B. M. Baruch and others for a more complete testing of the deposit. The results

of the drilling were highly satisfactory, and in the latter part of that year the Gulf Sulphur Company, with a nominal capitalization, was chartered. Nothing more was done after this campaign of drilling, other than to acquire property, until 1916.

The Gulf Sulphur Company, in that year, contracted certain drilling to the Producers Oil Company (now the Texas Company). Following the completion of that contract, the company began itself an active campaign of development, which resulted in the opening of the largest known sulphur deposit in the world.

On Jan. 27. 1918, the stockholders of the Gulf Sulphur Co. changed the name of the organization to the Texas Gulf Sulphur Co., and on July 16, 1918, the corporation was chartered with a capitalization of $5,000,000 (later increased to $6,350,000). At first the new company was disposed to postpone the construction of a mining plant, but the increasing demand for sulphur, due to the world war made advisable an immediate start in building. Construction was begun on August 13, 1918, and the plant was finished and placed in operation in March, 1919.

The first sulphur was produced on March 19, 1919. During the remainder of that year a production of over one thousand long tons daily was maintained, and during the years 1920 and 1921 about three times that amount. This large production has resulted in the accumulation of a sufficient supply in the stock piles to insure the ability of the company to fill all contracts, no matter what temporary shutdowns might occur in mining. The sulphur, like all Gulf Coastal sulphur, is of remarkable purity. Shipments are made on a basis of 99.5 per cent. pure when moisture free, but actually the sulphur is even purer than that.

Present Condition of the Industry

Following so closely the practically complete elimination of foreign sulphur from the American market and the invasion of the European market by the Union Sulphur and Freeport Sulphur Companies, it might be supposed that this tremendous additional production by the Texas Gulf Sulphur Company would have upset completely the equilibrium of the sulphur- mining business in the United States. This did not occur, however, for the latter company gained an outlet for its product by finding new consumers, especially among the previous users of pyrites.

At the present time the potential production of the Gulf Coastal mines is approximately 2,500,000 long tons annually. Of this, the Texas Gulf Sulphur is capable of producing over forty per cent., making it the largest sulphur mining company in the world.

Consumption of Sulphur

While a rough classification of the industries using crude sulphur as a raw material can easily be made, it is practically impossible to list completely those products in whose process of manufacture sulphur in one of its forms is used. In our every day life we are continually using articles which owe their present form or condition to the use of sulphur either as a constitnent or as a reagent. The great diversity of uses is indicated by a consideration of the very articles with which we are most familiar.

It is hard to realize that under this listing would fall not only the paper in the magazines we read, but also the glue, coloring matter and the photographic reproduction. In preparing the leather for our shoes, the paint for our houses, the coloring of our rugs, and even in the soap with which we wash, sulphur in some form is used. To carry the listing a little farther we may include the fuel and lubricant used in our automobiles the tires and the upholstery. Likewise the glassware on our tables, the preservatives in our food and the fertilizer which helped grow our foodstuffs must be included in the list.

A classification showing the industries using sulphur as a raw material and their relative importance as sulphur consumers throws an interesting side light on the economic importance of that material. As sulphuric acid production may be taken as an index of the economic condition of a country, so also may sulphur consumption be considered. An exhaustive study of this phase is out of place in an article such as this, but a few tabulations may prove interesting.

A broad division of the industries in which we are interested follows:

1. Acid and Chemicals
2. Acid Phosphate
3. Paper
4. Agriculture (other than acid phosphate)
5. Rubber
6. Galvanizing
7. Explosives

The relative importance as indicated in this list is taken from statistics of the past two or three years and is by no means to be considered fixed. On the contrary, the order may be changed from time to time, as many of these indnstries may be considered seasonal, and all are peculiarly susceptible to change under verying economic conditions.

It will be seen that an attempt has been made to simplify the list as much as possible. The close interrelation and the many subdivisions of the various industries are recognized by the writer, but without recourse to an extensive tabulation of statistics an attempt to expand would be successful only in confusing the listing.

A shorter tabulation showing approximate percentages may prove interesting.

A	Acid and Chemicals	35%
B	Fertilizer (Including divisions 2 & 4 above)	30%
C	Paper	27%
D	Miscellaneous (Divisions 5, 6, 7, above)	8%
	Total	100%

Sulphur Imports of Canada in Gross Tons

	U. S.	Other Sources	Total
1900	2,250	6,891	9,141
1901	1,500	9,510	11,010
1902	3,110	7,530	10,640
1903	1,630	9,280	10,810
1904	2,830	5,814	8,644
1905	2,800	7,650	10,450
1906	11,300	8,854	20,154
1907	5,480	6,063	11,543
1908	14,700	8,417	23,117
1909	7,650	12,000	19,650
1910	11,500	7,680	19,180
1911	13,400	8,155	22,555
1912	14,350	5,605	19,955
1913	26,000	6,555	32,555
1914	23,300	3,360	26,660
1915	34,950	3,915	38,865
1916	31,150	2,732	33,882
1917	70,750	4,249	75,000
1918	65,900	482	66,382
1919	86,900	76	86,976
1920	70,700	—	70,700
1021	106,000	10	106,010

Use of Sulphur in Canada

The above table, taken from various official publications shows the total sulphur importation of Canada for the year 1900 through to 1921 inclusive. For convenience it has been subdivided to show the tonnage derived from different sources.

The report is for fiscal years ending June 30, with the exception that for the years 1908, 1909, 1919, 1920, 1921 the fiscal year ends March 31.

The reflection of the remarkable growth of the sulphite pulp industry in Canada in the last twenty years is the outstanding feature of this table. Disregarding the small tonnage of sulphur consumed by other industries, we may say that the use of sulphur in the sulphite pulp industry has grown over 1,000 per cent. in that interval of time. From less than 10,000 tons yearly, it has increased until it now amounts to over ten times that quantity. Undoubtedly a certain part of this increase was due to the changing from pyrite to the cleaner, less bulky and more convenient sulphur but the amount thus involved can effect but a slight flattening of the progress curve.

A second observation, inevitably made after a glance at the table, is the marked increase in use of the sulphur mined in the Gulf Coast region. From a modest beginning, barely 25 per cent. of the total in 1900, it reached a maximum in 1920 and 1921, when but 10 tons was imported from other sources.

Many other comparisons with which we may not deal here will occur to the reader. The obvious question arising however is the future consumption of Canada. That it will amount to at leat 100,000 tons yearly, we may reasonably assume; but how much it will exceed that figure, time and Canadian initiative alone will tell.

A Budget From New York

by Kirby Thomas

Bauxite from British Guiana

A few years ago discovery was made of extensive deposits of bauxite, or hydrated oxide of aluminum, in the interior of British Guiana, not far from Georgetown. Some shipments of the product were made to England and the United States in a crude form, principally to supply the demand of the companies engaged in the production of metallic aluminum, although some of the material was used chemically to produce the various alums and other compounds. About 1917, the Aluminum Company of America, which is the largest producer of aluminum metal in the world and which practically controls the American market, secured by purchase and concession a very large area of the bauxite formation, which includes, according to reports, a practically inexhaustible supply of the material. The company has been carrying on extensive investigations and developments and is having built a fleet of six steamships, which will be used exclusively in the transport of the material to Gulf ports and St. Louis by water, from which point it will be distributed to the company's plants.

It was reported that at one time the British authorities were averse to having this important resource in a British colony pass into American control, but this matter seems to have been adjusted and the development of this new business promises to be large in volume and in value, and to become a factor in the development of American trade with a South American country, which has heretofore been in close commercial control of British interests.

The domestic supply of bauxite, found mainly in the southern states, is small and quite inadequate for the large and growing demands of the aluminum industry. Considerable quantities of the ore have been supplied from France. The standard grade, 52% alumina with less than 2% iron oxide, up to 20% silica and not more than 1% free moisture, is quoted at $10 per gross ton at the mine in this country. The improved grades bring up to $13 a ton, and special prices are paid for unusually high-grade material.

Minerals for Radio Apparatus

The mining industry is doing its "bit" to help along the development and perfection of the new radio apparatus which is coming into such great demand. Certain crystallized forms of minerals are required for the receiving equipment. The minerals most favored are pyrite or calcopyrite, the first a combination in chemical form of sulphur and iron and the other sulphur, iron and copper. It is claimed that the clearness with which messages may be received depends to a large degree upon the perfectness and quality of the crystal used. A demand for suitable crystals has caused the mining operators to search over their ores and to submit perfect crystals for the radio manufacturers. Meanwhile there is a constant search for a dependable supply of the best material. Few amateur radio enthusiasts, probably, are aware that there is one material in their apparatus that cannot be replaced by any substitute that scientists have yet discovered. This material is mica, a mineral substance found in nature that has unique dielectric properties: that is, it resists the passage of electricity even at remarkably high voltages. It seems unbelievable that thin sheets of this transparent material, only one thousandth of an inch thick, can successfully perform this necessary function. If it were not for mica the electric flows would be hopelessly tangled and the receiving set as well as the broadcasting apparatus would be useless.

BAUXITE IN TRANSYLVANIA

According to the *Mining Journal*, London, the bauxite deposits of Transylvania (formerly in Australia and now part of Roumania) are the largest so far discovered in the world, the tonnage of ore being estimated at 20,000,000 tons. The quality is said to be only second to that of French bauxite. During the war the deposits were worked at several places, but at the present time their exploitation is in the hands of only two firms—the Alumina Company and the Bauxita Company—who are exporting the mineral to Germany and Switzerland. Permission for exportation has been given on condition that in course of time the two companies named establish the manufacture of aluminium in the country itself on a sufficiently large scale to supply its requirements; this, it is considered, should not be very difficult, as the other raw materials necessary for the manufacture of aluminium are also available locally in adequate quantities. American aluminium manufacturers are said to be taking an interest in the mines, with a view of obtaining supplies of bauxite.

Mineral Production of Ontario

RETURNS FROM METAL MINES AND SMELTERS FOR FIRST NINE MONTHS OF 1922

Returns received by the Ontario Department of Mines from the metalliferous mines, smelters and refining works of the Province for the nine months ending Sept. 30th, 1922, are tabulated below, and for purposes of comparison the quantities and values are given for the corresponding period in 1921. Tons throughout are short tons of 2000 lbs.

ONTARIO'S METALLIFEROUS PRODUCTION — FIRST NINE MONTHS, 1922

PRODUCT		Quantity		Values	
		1922	1921	1922	1921
Gold	ounces	749,631	474,956	15,506,896	9,818,073
Silver	ounces	7,560,301	6,586,910	5,609,625	4,382,520
Platinum metals	ounces	113	915	7,771	41,060
Nickel (metallic)	lbs.	6,982,217	4,521,407	2,012,539	1,542,607
Nickel oxide	lbs.	470,529	975,310	81,160	197,812
Other Nickel compounds	lbs.	27,270	169,885	2,231	15,936
Nickel in matte exported (*)	tons	2,927	2,908	1,595,500	1,454,000
Cobalt (metallic)	lbs.	22,173	30,564	60,932	91,786
Cobalt oxide	lbs.	293,364	162,364	589,883	330,914
Cobalt — Nickel oxides and residues	tons	501	183	218,556	116,942
Lead, pig	lbs.	2,593,888	2,539,551	147,698	134,871
Copper sulphate	lbs.	22,553	99,553	1,310	5,973
Copper (metallic)	lbs.	2,104,323	2,926,407	245,489	330,084
Copper in matte exported (*)	tons	3,191	2,886	596,860	451,760
Iron ore (**)	tons	4,304	22	25,261	99
Iron, pig (***)	tons	12,296	82,318	291,926	2,079,729
TOTAL				26,928,637	20,994,172

* Copper in matte was valued at 8 and 9 cents per pound in 1921 and 1922 respectively, and nickel in matte at 25 cents per pound in both years.

** Figures in the table cover shipments to points other than Ontario blast furnaces.

*** Total output of pig iron from both domestic and imported ore was 237,827 tons worth $5,646,536. Figures in the table represent proportional product from Ontario ore.

Gold

A marked increase in gold output is the outstanding feature in Ontario's metalliferous production for the period under review. Not only is Ontario a leader among the Canadian Provinces, but for the full year 1922 will undoubtedly surpass California whose gold output was $15,704,822 in 1921. For the third quarter of the year Ontario's production was at the rate of over 22 million dollars per annum or about one-eighth that of the Transvaal for the same period, the average monthly rates being: Ontario 91,100 ounces; Transvaal—743,400. The Hollinger mine alone, now treating around 4500 tons daily, plans increased milling capacity equal to the total of Ontario's producing mines at the present time, or approximately 7000 tons per day. This expansion is dependent on increased power supply. Two new hydro-electric power projects are now being developed—one at Sturgeon Falls on the Mattagami river of 6000 to 7000 horsepower, and one at Indian Chutes on the Montreal River of similar capacity. Some of this energy should be available by February next.

For 1921 the exchange premium averaged 11.61 per cent. By the end of August 1922 Canada's currency had reached par. The exchange really amounted to a bonus for the gold mining industry. Canada is the first combatant country suffering currency depreciation as a result of the Great War to get back to normal. The total exchange premium received by gold mines for the 9 months' period was $183.354.

Gold Production, First 9 months, 1922

Source	Ore milled	Gold Output		Silver Output

The outlook for Ontario's gold mining industry was never brighter. Developments to date and ore blocked out give assurance of permanence. Several prospects are likely to become producers soon. There are many promising areas under development, such as Night Hawk lake, Lebel and Gauthier townships, West Shiningtree, Larder Lake, Matachewan, Painkiller Lake, and others, also some old mines in Northwestern Ontario.

Details of production are given in the above table.

Silver

Silver production has been well maintained. South Lorrain is attracting much attention as a result of the excellent showing being made by the Keeley and Frontier mines. Both the Miller Lake O'Brien and Castle-Trethewey mines at Gowganda made shipments. The average New York price of silver for the period was 68.137 cents per fine ounce. Shipments of ore, concentrates and residues over the T. and N. O. railway totalled 1015 tons to foreign countries, principally the United States, and 5796 tons to Southern Ontario refineries. Mines shipping over one half million ounces are given in order: Nipissing-2,959,411; Mining Corporation of Canada-1,289,401; O'Brien-884,030; Coniagas-826,820 and Keeley 540,350. A summary of shipments follows: Cobalt-6,473,970 ounces; South Lorrain-840,466; Gowganda-118,000; recovery from gold ores-112,890; nickel-copper refining-4,975 ounces, a total of 7,560,301 fine ounces.

Refineries Plants at Deloro and Thorold recovered 1,210,566 ounces of silver and marketed 3,221,791 lbs. of white arsenic worth $223,949. With the exception of the bulk of the metallic nickel and nickel oxide recovered by nickel refining plants, southern Ontario refineries produce all of the other nickel and cobalt compounds noted in the table.

Nickel-Copper

After a year's shut down at the Creighton mine of the International Nickel Company of Canada, work was again begun Aug. 26th. The Copper Cliff smelter re-commenced operations on Sept. 1st when the converters were put in blast, and the Port Colborne refinery re-opened on May 1st. Nickel-copper matte in stock held by the Mond Company has been cleared out for the first time since the armistice. The average price of electrolytic copper was 13.25 cents per pound for the nine months.

During the period 178,044 tons of ore were smelted and 8857 tons of nickel copper matte produced. In addition to nickel and blister copper, gold worth $1880, silver valued at $3450 and platinum metals as noted in the table, were produced. A large part of the nickel oxide marketed was produced from nickel-copper matte.

SICILIAN SULPHUR

Italian sulphur exports are confined almost entirely at present to European countries and the eastern Mediterranean. Antiquated methods of extraction in the Sicilian mines, combined with high daily wages paid to ineffectively utilized labor, have resulted in a generally high cost of production. Consequently, many former markets have been lost in whole or in part to American sulphur exporters despite the disadvantages for the latter arising from the comparative levels of dollar and lira exchange. During the nine months ending with March, 1922, Italy exported 54,402 metric tons of sulphur, valued at 44,666,740 lire, the amount shipped in the first quarter of 1922 being 36,434 tons, valued at 29,493,350 lire. Greece was the leading purchaser of Italian sulphur in the first three months of the current year, taking 16,280 metric tons, followed by France, with 4,344 tons; Germany, 2860; Smyrna, 1,588; Asiatic Turkey, 1,544; Austria, 1,340; and Yugoslavia, 1,045 tons.—U. S. Commerce Reports.

GOLD IN MACKENZIE AREA

An inquiry to the Geological Survey at Ottawa, ever a fruitful source of information and as yet far from fully appreciated by the public, has brought following information about gold in the Mackenzie River district, which has been the subject of newspaper reports recently.

In regard to the reported strikes of gold quartz in the Mackenzie area, the only one that has come to the attention of the Geological Survey is the prospect on Cariboo Island at the east side of Great Slave Lake. The rocks were discussed briefly in the Summary Report of the Geological Survey, 1921 part B. At the time the Geological investigation for that report was made, very little development work had been done but this last summer a shaft was sunk to the depth of 60 feet and some very good showings of gold are reported to have been found. The property has not been inspected officially since the recent developments were made and the extent of the discoveries is unknown. Samples that were obtained from the property by several members of the Topographical Survey, who were mapping that part of the lake this last summer, showed free gold in very encouraging amounts but how much gold bearing material is represented by such grab samples has, as far as I am aware, not yet been determined.

Placer gold has been reported on several streams that enter the Mackenzie. The area of most interest this last summer was "The River between Two Mountains" which enters the Mackenzie near Old Fort Island south of Wrigley. As can be seen from the map by Dr. M. Y. Williams published in the Summary Report, G. S. C. 1921, pt. B. the river flows over sedimentary rocks that are not likely to be gold bearing.

During the winter of 1921 a number of claims were staked for placer on the South Nahanni River, tributary of the Liard flowing out of the mountains to the west. It is certain that colors can be obtained at many places both on the South Nahanni as well as the Liard but whether the gravels are rich enough to work commercially has not yet been proven. Very little development work has been done on the South Nahanni but it is of interest to note that prospectors from that country have brought out samples of Galena (very slightly silver-bearing), and Chalcopyrite, the former being reported to occur in some considerable amount. It is claimed there are intrusive rocks on the South Nahanni but as far as I have been able to learn no samples have been brought out. However the finding of intrusive rocks is not new in the mountains to the west of the Mackenzie. Mr. J. Keele reported them on the Gravel River (*A Reconnaissance across the Mackenzie Mountains on the Pelly Ross and Gravel rivers*, G. S. C. 1910, pub. 1097, page 42.) and they are known elsewhere in the Norman area. There is thus reason to believe that they are present on the South Nahanni as has been reported.

Investigations by the Electrolytic Zinc Co. of Australia have showed that sulphuric acid can be manufactured with greater economy from pyrites than from the sulphurous gases produced by the metallurgical treatment of their ores. The sulphuric acid is required to treat the phosphate rock imported into Australia for use as fertilizer.

Operators on the Malagash, Nova Scotia, salt property have discovered, at a depth of 200 feet, a six foot face of almost pure white salt, which analysis has proven to be 99.4 per cent pure. The owners state there is a very large supply of this product and that it is apparently improving in depth. The discovery of the salt bed has opened a valuable new industry in the district.

PROSPECTING REGULATIONS ALTERED

Staking by Proxy on Dominion Lands Now Allowed

Provisions which facilitate prospecting for minerals naturally increase the rate at which the development of our great mineral resources proceeds. In his address at the annual general meeting of the Canadian Institute of Mining and Metallurgy held in Ottawa, in March, 1922, the President Mr. C. V. Corless, an officer of one of the big corporations developing nickel deposits at Sudbury, referred to the great area of Canada which is suitable for prospecting for minerals. In addition to large areas in Quebec and Ontario, he pointed out that two-thirds of the province of Manitoba , one-quarter of Saskatchewan, two thousand square miles of Alberta, and a large portion of the Northwest Territories were also in the pre-Cambrian area, a formation which he claimed should be thoroughly prospected, as many of the big mines of Canada were in that formation.

There are many people following other occupations than mining who would like to participate in the mineral wealth of the great unexplored regions. They can always buy stocks in companies formed to develop new finds, but this does not appeal to them to the same extent as backing a real prospector and sending him into the field. Such persons are unable to leave their present occupations and would probably not be of much use in the field if they attempted to engage in the business of searching for minerals.

Real prospectors are not plentiful, and when found, it is to the interest of the whole community that they should not lack the means to enable them to continue prospecting. The supplying of a prospector with food, tools, and equipment is known as "grubstaking." An agreement is usually signed by the prospector by which he agrees to transfer a prescribed interest in any location he makes to the "grubstaker."

To enable any person to assist a prospector, a provision has been inserted in the Quartz Mining Regulations which apply to all Dominion lands that a prospector, before proceeding on a bona fide prospecting trip, may file with the mining recorder of the district one or two (but not more than two) powers of attorney to stake. Accompanying each power of attorney there should be evidence in the form of a declaration that the person granting the power of attorney has furnished the means to enable the prospector to proceed on the trip. If the prospector succeeds in locating a deposit of minerals which he considers advisable to stake, he can locate a claim for each of the persons who granted him a power of attorney to stake, in addition to locating one in his own name, and in due course he can file applications on their behalf with the mining recorder, but the grants for the claims are issued in favour of the "grubstaker" who in this way acquires title.

By means of the plan provided, any person over eighteen years of age, irrespective of nationality, residing any place in the world, can grant powers of attorney to stake to prospectors desiring to prospect on Dominion lands. This provision applies to all minerals defined as such in the Quartz Mining Regulations, and a similar provision appears in the Yukon Placer Mining Act and in the Placer Mining Regulations relating to Dominion lands outside of the Yukon Territory.—From "Natural Resources," Ottawa.

COAL AND THE RAILWAYS

About half the freight loaded on our railways, according to an estimate made by a well-informed man experienced in both mining and transportation, is contributed by the coal mines. This portion includes coal loaded at the mines and coke loaded at the ovens, both consigned to consumers all over the country, and coal loaded for the railroads themselves, as well as articles of mine equipment and supply loaded at industrial centers more or less distant from the coal mines. Even though this figure may later be shown, on fuller presentation of the facts, to be somewhat high, the big outstanding truth is that the coal mines and the railways are co-partners on a large scale in the business of the country. This co-partnership, based on mutual interest, — the railways being the largest purchaser of coal and the mines being the largest customer of the railways—gave special significance to a conferenee held recently between a representative committee of the American Railway Association and the United States Coal Commission.

The railway men present at that conferenee showed their desire to co-operate in the work of fact-finding by suggesting subjects on which they could contribute statistical facts. The perennial topic of car shortage is only the introduction to the larger questions—What investment in railway equipment is justified to meet the demands of an overdeveloped mining industry? What can the public afford to pay to accommodate its own seasonal demand for coal? The operating officials of the railways can also point to the effects of seasonal movement of coal and other commodities on the cost of operation of their roads.

The coal operators are themselves not unmindful of the peak demand for transportation arising in part from the seasonal demand for coal. One large mining corporation in the Middle West has several times made its annual appeal to its customers for early purchase of coal in the form of a full page reproduction of a photograph of two huge locomotives snow-bound on the track, with the simple legend "Lest you forget 1917-18." Such a reminder is pertinent every year, for the greater part of the American public either forgets or has never learned the obvious connection between snow-clogged freight yards and delayed coal at the very time when coal is most needed. How much of this seasonal burden on the railways can economically be avoided is one of the questions the American Railway Association can help President Harding's Coal Commission to answer. Possibly the consuming public can itself also help in lowering the cost both of hauling coal and of mining it.

In Alberta and parts of British Columbia, Canada has the same problem to face. It is quite possible that, if all those interested in the production and use of coal combine to solve the problem, its price to the consumer can be lowered at the same time as the wages to the miner, profits to the operator and freight for the railways are made more consistent and more satisfactory to all.

A Russian oil geologist, Captain de Hautpick, has published in Australian and London mining journals a series of articles designed to prove that anticlines are unnecessary to the accumulation of petroleum in commercial quantities. He supports his conclusion with experimental data.

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

BRANCH RAILWAY MOOTED.—It is understood that the T. & N. O. Ry. Commission is considering the construction of a branch line east from Swastika. This line, if built, would serve a rapidly developing mining district, and would pass through Kirkland Lake, the Pancake Lake district, where the Crown Reserve is meeting with good results, Gauthier Township, in which the Argonaut Mine is situated, and would be carried to the vicinity of the Quebec border, where it would help to serve the newly discovered district in Quebec, about which such favorable reports are heard. These different gold sections deserve much better transportation facilities than they have at present, and the construction of a branch line to serve them would stimulate development. Despite the greatly increased importance of Northern Ontario's gold camps, the T. & N. O. has not, during the past ten years, built a single mile of railway to serve the mines.

POWER FOR PORCUPINE.—Officials of the Northern Canada Company expect to have 3000 h.p. from the new Sturgeon Falls development ready to distribute by the middle of January. This will take care of immediate needs, but will not allow for any expansion in the camp. The Northern Canada Power Company, with this latest development, would appear to have almost reached the limit of the power which it can produce, and it is evident that something will have to be done meet the growing needs of the district. While this additional power from Sturgeon Falls will take care of present consumption in the camp, it will not permit of sufficient power to supply any new mines which are developed, or to take care of the expansion of the present ones. The Hollinger, with its proposed increase in capicity, will need a much larger amount of power. This company does not appear to have received sufficiently satisfactory guarantees from the Ontario Government to permit of its going ahead with the development of power on the Abitibi River, as the company feels that the Government restrictions are altogether too severe. It is understood that the Great Northern Power Company, which was recently known as the Matachewan Power Company, will extend its transmission lines to Porcupine, and will take care of the Davidson, at least. It will also pass close to the Argonaut and Pancake Lake sections. If this company meets with sufficient encouragement it should be able to relieve the situation. The capacity of its present development is understood to be only about 6500 h.p., but the company owns another power site further up the river, which is capable of greater development.

COBALT.—A Canadian company is being formed to take over the Keeley Mine in South Lorrain. The present company is an English one, and the shares are not listed in this country.—The Nipissing has dropped its option on the Burnside-Bryce claim, which lies to the east of the Burnside property in Kirkland. Several diamond drill holes were put down, but the results obtained were not sufficiently encouraging to justify the Nipissing going ahead with further development work.—Shipments of residues from the camp still continue high. During October the Mining Corporation shipped 1176 tons and the Nipissing shipped 889 tons of residues. The Coniagas was the only other shipper, with one car of 44 tons. During the week ending November 24th the McKinley-Darragh, with a car of flotation concentrates, was the only shipper from Cobalt.

KIRKLAND.—The annual report of the Teck Hughes, while showing satisfactory results for the past year, holds out much greater encouragement for the future. During the year ending August 31st, the company treated 43,300 tons of ore, averaging $11.11 a ton, at a cost of $7.09 a ton, and made a net profit of $111,800. The balance sheet still shows a deficit of $366,241, practically all accounted for by the outstanding bonds, which amount to $339,000. As the cash on hand amounts to $175,000, and as profits during the past few months have been running exceptionally high, it is believed that the bond indebtedness can very shortly be paid off. The average grade of ore for the year was slightly over $11.00 per ton, but in July the grade was $23.14 and in August $23.50. In September, which is not included in the fiscal year, the grade was $43.79 a ton, and the mill recovered approximately $118,000, from which it is expected that a profit of around $70,000 could be made. The report states that the year's operations were very satisfactory, and that important ore bodies were found in the No. 1 vein at the 7th. level which hold out very good possibilities for the future of the mine at depth.—The Thompson-Chadbourn Syndicate has taken an option on the Smith properties in Catharine Township, and will sink a 100-foot shaft. This syndicate is also very active in Quebec, and is doing a considerable amount of work there.—The Argonaut Mine has made an important discovery on the 500-foot level, and it is understood will proceed with the completion of the mill.

PORCUPINE.—The McIntyre is continuing its drilling programme on the Schumacher Veteran claim, adjoining the Dome, and while no reports have been given out regarding results, it is understood that nothing of much importance has been cut. The company is, however, meeting with exceptionally favorable results on the McIntyre property, and the No. 7 vein has now been proved for a length of 1200 feet on the 1870 foot level, and it is understood to average approximately $20.00 across a width of 12 feet. This makes it one of the most important ore-bodies in any mine in Canada. The company has declared a dividend of 5 per cent., payable January 2nd. Some little trouble has been experienced by the settling of the foundations under the new mill building. It is not thought, however, that the trouble will be very serious. Work at the Vipond has been temporarily halted on account of a break to the machinery. Repairs, however, will be made in a few days. The company's shaft is down to 1000 feet, and three new levels will be opened up between that depth and 600 feet.

During the first half of 1922, calcium carbide to the amount of 2119 tons was made in Tasmania. The embargo on the importation of carbide under which this industry in Tasmania was fostered is now abolished, but it is to receive further protection from the Australian anti-dumping act.

NOVA SCOTIA

Rail Mill Operating.— The rail mill at the Sydney steel plant which has been idle since last February, began to roll rails in the first week of December. A number of mechanics have for some time past been making repairs and putting the mill in good condition. The order on hand amounts to twenty-five thousand tons, and it is hoped that other orders may be booked up before this one is filled.

The Newfoundland Venture.— A powerful group of British capitalists has acquired control of large areas of pulp land in Newfuondland, and intend to construct a mammoth paper plant costing eighteen million dollars. The British Treasury has guaranteed the interest on nine million dollars of bonds toward the project and Newfoundland the remainder. The plant will be located on the Humber River at Bay of Islands on the west coast. It is a wide, deep, rapid stream, which is capable of developing an enormous amount of electric power. For several miles from its mouth it is navigable for ocean-going steamers, and for shipment by water, all that is necessary is the erection of suitable piers. The people of Newfoundland are said to be enthusiastic about the scheme. They realize that the addition of nine million dollars to their country's liabilities will mean heavy taxation, but they are willing to undertake the burden, strong in the belief that in time the investment will give large returns.

Works Committee Refused.— The proposal to form a works committee to deal with disputes arising at the Sydney steel plant, made by Superintendent Bischoff, was turned down at a meeting which was more representative of the Labor Party than of the Sydney steel works employees. A counter proposition was made which smacks strongly of the One Big Union. It carries with it a six-hour day and five-day week. This is labor politics, pure and simple, and goes to show that the labor leaders of Nova Scotia are without a proper sense of responsibility and are unfit to direct the affairs of the workmen. Sydney steel plant has not yet reached the stage of producing to capacity, yet there are not wanting those who would, by their theories and fads destroy the chances of adding to the comparatively light orders now being filled.

Classes Well Attended.— The First Aid to the Injured classes have been in operation for two successive Winters. The number of miners and others from the Glace Bay district attending was close on 500. Of these about 250 received certificates after successfully passing the examinations. Only twenty-five of this number qualified for the Voucher that is given to second year men. Considering the labor turmoil, the terrific snowstorms and the epidemics of last winter, the progress made along this line is atisfactory.

The two hundred and fifty trained men who did not test their knowledge by examination may be counted as an asset and they will, with the others, do much useful work round the collieries and the works.

Inspection of Wabana Mines.— Vice-President D. H. MacDougall made a tour of inspection of the Wabana ore plant, Newfoundland, and expressed himself as being highly pleased with its splendid condition and the progress of development. It is the intention of the present management to follow the example of the Cape Breton colliery district and plant flower gardens, use paint freely and to generally beautify the grounds. From what we know of the tastes of mechanical Superintendent J. B. Petrie, who is fond of gardens of all kinds, Wabana will next year put on a new appearance.

Rapid Loading.— The S. S. Daghill, loading ore at Wabana, took 11,000 tons in four hours and twenty minutes. Only one chute was used. The actual loading time was 2 hours and 45 minutes. Shifting the ship for the ten hatches took 1 hour and 45 minutes. The loading facilities at Wabana are almost perfect.

Iron Mine Re-opened.— The No. 3 ore mine, Wabana, which for the past three years has been filled with water, has been pumped out and is again a producer.

Clean Stock Piles.— All the old ore stock-piles are being cleaned up and refuse ore taken away. The new stock-piles will begin on clean floors, like coal piles and each year's refuse will in future be removed with the pile. This will give the stock-piles a clean fresh appearance.

BRITISH COLUMBIA

Government Engineer Describes New Placers.— Cedar Creek, Cariboo district, was boomed as a new and wonderfully rich placer field early this year. Prospectors hurried into the district as soon as the snow disappeared. There was the confusion usually met with in "rushes", there were many disappointed, and disgruntled ones returned to give the discovery a "black eye." For these reasons it is gratifying to be able to quote J. D. Galloway, Government Mining Engineer, as saying that the Cedar Creek strike is one of great importance, the outstanding incident in placer mining development of this Province of the year. "The total production of the Camp", he states, "has been about $75,000, almost all of which has been produced by rockers. This," he observes, " is a very creditable start for the first year and from all indications a larger production should be made next year."

But it is not so much the actual value of the Cedar Creek find that Mr. Galloway dwells upon, although that it not minimized, as its importance to the entire Cariboo. The gold was on high ground, a ridge that there was reason to believe had been the original bed of a creek, and if the theory proved sound in this instance is there any reason why it should not be applied with success in many other places in that great central plateau? Mr. Galloway answers, "No", and believes that the proving of Cedar Creek has opened up wide possibilities for placer discovery and the development of gold mining in the historic Cariboo.

Mr. Galloway's account of Cedar Creek is the first description of the "find" by a government engineer and therefore is of special interest. He says:

"Cedar creek was worked for placer gold in the sixties and a certain amount of gold was taken out. These old workings extended from Quesnel lake upstream for about two miles. This part of Cedar creek runs in a deep gorge for the most part, except near the lake where there is a delta deposit.

"In the fall of 1921 Lyne and Platt commenced prospecting on the southern side of Cedar creek about one-half mile back from, and 600 feet above, the creek. In this work they were carrying out an old theory that the gold found in the bed of Cedar creek came from an old high-level channel through which Cedar creek had cut. The discovery was made in a small, shallow draw or flat depression which drains into the canyon of Cedar creek. The discovery was staked as a lease by Platt, but owing to faulty location

the discovery ground was later found to be on Steven's lease, a later location. Pay ground was, however, found on the Platt lease in a draw lying a little to the south-east of the discovery draw. Lyne staked a lease to the north of the Platt lease, but so far no pay ground has been found on it. The Sheridan lease adjoins the Platt ground to the south-east and this contains good pay.

"These placer deposits are unique as they differ very considerably from the usual types found. The country is more or less a flat plateau and heavily wooded. There is no well-defined creek but the abundance of seepage water makes it difficult to sink holes without pumping machinery.

"In the discovery draw the bedrock is only from 4 to 6 feet below the surface. In many places there is 2 to 3 feet of black vegetable muck and then 2 to 3 feet of broken bed-rock, gravel and inter-mixed clay. The gold occurs in this mixed gravel or on the bedrock and partly in crevices in the bed-rock. On the Platt lease the ground is from 6 to 12 feet in depth. Generally the upper half of the gravel consists of glacial drift, which is practically barren of gold, and the lower half is gold-bearing with probably the greater portion at and near bed rock. The richest ground in any of the diggings is on the left bank of the discovery (Stevens lease) where some phenomenally rich pay dirt has been taken out. In six days 528 ounces of gold was taken out with two rockers working; these rockers each handle about 1½ cubic yards a day. This ground therefore carried about $500 a yard.

"There seems little doubt that these deposits are pre-glacial in age, although in part, as in the lower end of the discovery draw, they have been displaced and partly re-worked by glacial and post-glacial action. The gold is coarse and nuggety and from its physical appearance has not travelled far. In value it averages about $17 an ounce.

"It is reported that the deposit on the left bank of the discovery draw is continuing in a south-westerly direction and it is now evident that it is of more importance than the discovery draw itself. This ground is from 6 to 15 feet deep, with pay in the lower 2 to 4 feet of gravel.

"The Stevens, Sheridan and four other leases were obtained under option by the Cedar Creek Mining Company early in the summer. This company has carried on steady operations and has had from 2 to 4 rockers continuously operated. Late in the fall a small plant was put in, consisting of a gasolene engine and pump and line of sluice boxes. Water is obtained by a line of ditches to a small reservoir and from this the water is pumped up to the head of the boxes. It is difficult to get any water for sluicing, but in this way the water is caught by a return system and used over again.

"The Platt and Lyne leases are now controlled by McCaskill and Wright and the Platt ground has been worked by means of rockers. Litigation and injunctions tied up the Platt property during most of the summer but now all this has been settled."

* * *

Government Grant for Roads.—Some $95,000 is expected to be spent by the Provincial Government next year in road construction in the Portland Canal mining division. There is some work from the townsite of Stewart to the wharf that will mean an expenditure of $30,000 and it is stated that two spans are to be thrown over the Bear River at the site of the present bridge, costing between $25,000 and $30,000. The Bear River waggon road is to be improved, it being understood that the construction is to extend as far as American Creek. All this would indicate that the government is alive to the importance of mining developments in this section.

G. A. Carlson, of the firm of Seims & Carlson, Spokane, Wn., is quoted as stating that he has a contract for the building of 13 miles of railway up the Salmon River Valley. The line is said to be planned to start from tidewater at a point near Hyder, Alaska, proceeding up the east side of the valley, thus serving a number of promising properties.

Grant Mahood, president of the American Mining and Milling Co., operating on Fish Creek, Salmon River, states that developments continue satisfactory. He says that No. 1 vein is showing up well and adds "Have struck a body of high-grade ore averaging $100 to the ton." This is the result of work on a new tunnel which was started some months ago.

Alice Arm.—At Alice Arm, Portland Canal district, the Esperanza Mine is being operated steadily. Milling ore now is being taken out but the owners expect to break into the high-grade soon. They will ship the latter ore during the winter.

Activity near Kamloops.—The Windpass Mine, Chu Chua, near the town of Kamloops, a lode gold property, has been taken over by General Leckie with whom is associated W. R. Wilson, president of the Crow's Nest Pass Coal Co., and Messrs. Trites and Wood, of Fernie. The Queen Bess, a silver-lead property in the same district, has been reopened. There are said to be indications of natural gas in the vicinity of Kamloops and the oil and gas rights on Hudson's Bay property are being secured by enterprising citizens who plan to do some drilling.

Good Production of Gold-Copper Ore.—The Belmont Surf Inlet Mine, on Princess Royal Island, off the West coast, is producing at a rate of about 12,000 tons a month, and the ore is said to average $9 a ton in its values. More plant and general equipment are being installed.

Cariboo Pioneer Dead.—Col. "Bob" Stevenson, said to be the last of the pioneers of the Cariboo gold rush, died recently in Vancouver. He was 84 years old and came to British Columbia in 1859. Perhaps the best known of Col. Stevenson's adventures was his journey from the Cariboo to Victoria in the sixties with the body of the wife of "Cariboo" Cameron. Cameron, who struck it rich in the Cariboo, offered $12 a day and $2,000 to anyone who would accompany him with his charge through the snows of a hard winter. All refused save Stevenson, and the two, it need scarcely be said, suffered terrible hardship before reaching their destination. The Colonel then refused any pay for his services.

Good Production from Mayo Camp.—It is reported from Dawson that the winter output of the Mayo Silver Camp will exceed expectations. Keno Hill Ltd. will produce about 1,000 tons and the Treadwell Yukon Ltd., about 3,000 tons before the opening of navigation. This will all be delivered at Mayo Landing over the snow and every team available in Dawson has been requisitioned to assist in transportation. The Treadwell Yukon properties are hauling with caterpillar tractors with success. It is stated that a trip

body of ore has been opened up on the Treadwell-Yukon lode, the report being that the vein has widened to 28 feet at the 200-foot level. Last fall on the same level a 10-foot vein was being worked, containing 300 ounces of silver to the ton with a little lead. If the rich ore continues to the 400-foot level it is proposed installing a concentrator next year. There also are reports of remarkable showings in the Shamrock Mine, while the Yukon Gold Company is said to have opened a new vein on the Roulette Claim.

EXPLORATIONS IN PEACE RIVER DISTRICT.— Indications that point to the possibility of the existence of oil in the Peace River District are reported by engineers who have been exploring the territory for the British Columbia Department of Lands. It is stated that the geological formations would lead to the expectation of finding oil, while in drilling operations coal seams were struck and natural gas flows tapped.

Examination of the Peace River District has been under way since 1919. The area covered lies between the Peace River on the south and Graham River on the north, and comprised 400 square miles.

A general reconnaissance was made by the late Prof. J. C. Gwillim in 1919, who recommended detailed explorations of certain sections. Prof. E. Spieker, of the John Hopkins University, was employed in the following year to report of the section to the south of the Peace River. That lying to the north of the river was examined by John A. Dresser, consulting geologist of Montreal, and Prof. Alexander McLean, of the University of Toronto.

Drilling operations were started in June 1921. Diamond drills were used and the cores of six borings, ranging from 1,027 to 2,525 feet in depth, show three distinct geological formations. They are the Dunvegan, St. John and Bullhead. Of these the St. John formation is regarded as the more important, being of marine origin and a possible oil-bearing stratum. This underlies parts of both British Columbia and the Province of Alberta. From the different borings, it is stated, saline water, inflammable gas, and thin films of oil were obtained. The gas from one of the holes was piped to the drillers' camp where it was used for heating purposes.

The most satisfactory results were obtained from Hole No. 6, which was drilled about nine miles from Hudson's Hope. It went to a depth of 2,525 feet and passed through about 1875 feet of St. John shale. A seam of sand resembling the tar sands of Alberta was encountered at depth. This was about two feet in thickness and contained a high percentage of oil having a paraffin base.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eighth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invitedto write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

A MERRY CHRISTMAS

At the present day, when our thoughts are all running after the precious metals, it is well to bear in mind that iron is still the most precious of all metals for the comfort and progress of mankind.— R. G. Leckie — 1897

A PROMISING IRON ORE DEPOSIT

One of the few alternatives at present available for the establishing of an iron ore industry in Canada is the concentration of low-grade magnetic ore and subsequent agglomeration of the fine particles of pure magnetite. One attempt to apply this process of beneficiation made at Moose Mountain, near Sudbury, Ontario, has so far failed of commercial success, though there is still hope that the Grondal briquettes that are made there, or perhaps sinter made by slightly modifying the process, may bring into the market the 25 million tons or more of iron ore that have been blocked out there. There may be, however, more favourable localities in Ontario for the establishing of a large scale concentration plant for magnetic ore.

One of the principal items of cost against the iron ore used in the blast-furnaces of Ontario is railway freight. If Canadian iron ore could be produced in such a locality as to carry a minimum of railway freight charge against it, the chances of commercial success would be much enhanced. Such a deposit of ore is that on the Mattawin iron range, where it touches the main line of the Canadian National Railway, fifty miles west of Port Arthur.

Today we print a description of this portion of the Mattawin range by Mr. Frank Hille, who has been principally responsible for the exploration that has been done on the lands he describes. His data show a deposit of ore of first rate proportions, sufficient for the adequate supply for an indefinite period of the largest concentrating plant that could possibly be contemplated. As with the ore on which the new plant at Babbitt, Minnesota, is now operating, part of the ore is amenable to complete separation from the associated silica without fine crushing; that is, the silica is in part inter-banded, while in other places it is intimately intermingled with the particles of iron oxide. The tenor of the ore in iron is noticeably higher than the Babbitt ore, and it is equally free from sulphur and phosphorus.

It is the location of this deposit of iron ore, however, that makes it of such promise. The only investment needed for railway facilities is for private sidings. The distance to Port Arthur, fifty miles, is from one-half to one-quarter of that necessary for ore on the American side. The quantity of ore available by quarrying, above the railway level, is stupendous.

Pending the result of the experiment at Babbitt, it is not at all likely that any concentrating plant on the same or a similar model will be erected in Canada. Should the result at Babbitt be commercial success, there is no doubt that Canada will soon have a similar plant. Such a plant should be located at the place where nature offers the best inducements and where the least investment is necessary. It may be that the Mattawin range offers these inducements.

A GOOD SPECULATIVE INVESTMENT

This week we have the pleasant duty of commenting once more upon a straightforward and well-conceived mining stock flotation. The Night Hawk Peninsular Mines, Limited, have offered for public subscription at par (one dollar) 300,000 shares of capital stock, out of an authorized issue of $5,000,000. The proceeds of this issue are to be used for the erection of a mill, and to pursue development work underground until the mill shall be a source of income.

Even in the newspaper advertisements, the information given as to properties, ore reserves and hopes for the future are well within the limits that would be prescribed by a well-informed mining engineer. We would judge that such an engineer has scrutinized the advertising "copy" before it was issued for publication. This is as it should be.

The two Canadian representatives on the board of directors provide ample security for the *bona fides* of this new gold mining company. They are no mere dummies, whose names might be used to influence the unwary or ignorant. Mr. Grover is a well known lawyer who has for years past specialized in practice connected directly with the mining industry where it is at its soundest and best. Mr. Taylor represents a firm of financial brokers whose reputation is unimpeachable. It is a pleasure to find that these representatives of the legal and financial professions have stood sponsors for a speculation in mining that is at least on a par with any other sound speculative investment.

BETTER BUSINESS TRAINING FOR ENGINEERS

Today we print a brief announcement from the Carnegie Institute of Technology, Pittsburgh, of an investigation carried on by two of their staff. The result is to show that 67 per cent. of the Carnegie Tech. graduates from 1908 to 1921, in all branches of engineering, are engaged in managerial or commercial work, as distinguished from technical employment. To meet this condition, Carnegie Tech. has instituted a separate course in Commercial Engineering.

There is no doubt that a similar investigation among Canadian engineering graduates would disclose much the same state of affairs. Those who are responsible for shaping the courses in our engineering schools are at least dimly aware of the facts of the case, but the action they have taken to meet the need indicates that their comprehension of the facts is very dim indeed. A little more English, a hurried glance at economics, and some brief references to finance and management by the technical mentors, comprises what the average engineering graduate in Canada gets today to prepare him for the managerial and commercial duties he is more than likely to assume before he has advanced far in his profession.

There is no doubt that the average college courses is already too congested, as well as too diffuse, to allow of additional studies on management and commerce. On the other hand, there is no doubt that most technical graduates are in this respect ill prepared for their life's work; they must "pick up" information and ideas on these all-important phases. If their teachers were well versed in the economics of business and in industrial management, there is no doubt that the spirit of the director or manager would pervade all their teaching, without formal instruction. This may be the way out. In any case, we are confident that the problem needs but to be faced squarely by our educationists, and an adequate solution will be found.

RESEARCH

It is a sick world that we are living in. It would be a very much sicker world if doctrinarians had their way. We confess to an impatient distaste to much that is written and spoken, by men who should know better, recommending curative measures.

The world's malady is not mortal. Weakness and fever are the unavoidable results of the phlebotomy of war.

It is good to hear commonsense from high quarters. Sir Auckland Geddes, British Ambassador to the United States, speaking recently at the University of Pennsylvania, referred thus to the world-wide need for research:—"As one looks round the world to-day and "sees in country after country the power, the direction "of force, passing from the hands of the people that "have long held that power, sees wealth being des-"troyed, sees all the surplus margin of wealth dis-"appear, one realizes that there is cause to take steps "to spread the appreciation of research, so that no "shift of political power can possibly take place that "will not leave that power in the hands of those who "at least understand something of the importance of "research, *which has to be supported because it can "never be self-supporting.*"

The italics are our own. The sentence italicized is well worth keeping in mind. It requires supplementing, however, by the statement that research to-day, whether conducted by governments, universities, or manufacturing firms, although it is not directly self-supporting, yet pays for itself a hundred-fold.

Scientific and industrial research is the corner-stone on which the edifice of Canada's prosperity must be built if it is to be architecturally sound.

A BOUNTY ON PEAT

An interesting development in the peat situation is the announcement by Premier Taschereau that the Quebec government is prepared to pay a bounty on peat fuel produced in the province. The amount of the bounty has not been announced; but no doubt it will be made sufficient to ensure commercial peat manufacture in the immediate future.

A more interesting phase of the situation is the effect on peat production in Ontario, where it is most needed. The Ontario government has spent a large sum of money in developing the present effective mechanism for making peat fuel. Now, by an astute move, the Quebec government seems about to reap the benefit of this experimental work for its own people. Whether or not the Ontario government will counter by offering a similar bounty for the manufacture of peat in Ontario, remains to be seen.

Any active measure that will provide against the domestic fuel shortage that will surely come if the strike arranged for next spring takes place, is well worth considering. It would be calamitous were the fruits of the labour and investment on peat during recent years not made use of fully during next summer

JOHN DAVID MACKENZIE

On Friday, December fifteenth, John David Mackenzie, chief of the British Columbia division of the Dominion Geological Survey, died at the military hospital at Ste. Anne's, near Montreal. After finishing his field work for the season, Dr. Mackenzie came east to this central military hospital to undergo a course of treatment of a wound he received on active service. The first of what was to have been a series of slight operations proved fatal. His wife was with

him throughout, and his friend and chief, Dr. Charles Camsell, spent the last few hours at his side. Canada has lost a brilliant son, the Empire, a good soldier, and the mining fraternity, a member who had already endeared himself to a host of friends. A simple funeral service, conducted by a fellow-soldier, likewise from Cape Breton, was attended by a circle of friends in Montreal, with the addition of some from Ottawa. The burial will take place in Vancouver.

The Canadian Mining Journal offers its sympathy to the widow, and to the surviving members of Dr. Mackenzie's family.

EDITORIAL NOTES

In discussing the questions of unemployment and migration in a recent issue the *Mining Journal* of London says: "History has shown us over and over "again that rich mining discoveries will bring emi- "grants to any part of the Empire. If Australia could "find a new gold field there would be no need of "emigration schemes." Canada has now just such a new gold field, in the midst of a vast tract of agricultural land that promises to make a huge and continuous contribution to our national agricultural wealth when it shall have been cleared and tilled.

The expected rise in metal prices in the United States, due to the new tariff schedule, has taken place promptly. The Fordney tariff has not affected seriously the production of Canadian minerals, nor is any such tariff likely to do so. A more likely effect is to stimulate the full use of Canadian minerals in Canada, and the export of the more valuable manufactured products. In the long run, the high tariff will mean a higher cost of living, and consequent higher cost of production in the United States, which will give Canada an advantage in competing for overseas trade. This might even, indeed, make the American market more attractive, and so nullify the express purpose of the high tariff.

The nickel industry, though not yet booming, is in a state of activity that is very encouraging, and indeed highly satisfactory considering the conditions that have prevailed until recently. The faith of those responsible for the direction of the industry, and their energetic efforts to convert that faith into "works," is now fully justified. Canada's ability to pay her debts abroad and to finance new development at home will be enhanced not a little during the coming years by virtue of her prosperous nickel industry.

One seldom hears of mining in Saskatchewan. Yet there are mines there, in the lignite seams, that flourish by seasons and are no great drain on the resources of the owners when they are idle. If haply there should be devised some process for converting lignite into coke, with oil, tar and ammonium sulphate as by-products and plenty of surplus gas wherewith to generate electric power, then we shall hear much more of Saskatchewan's mineral wealth. Meantime the northern half of the province, which is underlain by rocks of pre-Cambrian age, remains virtually unexplored and awaits the work of the prospector, and after him the builder of railways, to yield its quota of natural wealth for human use.

It is a highly satisfactory development in the power situation in Northern Ontario that arrangements have been made to develop an additional amount of power at Indian Chutes on the Montreal River, sixty miles to the southeast of the Porcupine camp. The financial auspices under which this newer development is being made are such as to ensure thorough and expeditious engineering work in the construction, and sound financial arrangements in power contracts. The maximum of power obtainable from this source is, however, quite insufficient for the needs, present and prospective, of the Porcupine camp, and the duty of providing for this power still presses upon the provincial authorities, in whose control the water right is still vested.

The whimsical account of George Du Maurier's "Recollection of an English Gold Mine" dug up by Mr. Murray and described by him in this issue, will be considered by many as typical of mining finance. It is so in too many cases. The habits of some mining stock promoters of sixty years ago are the same as certain of those today. Fortunately, it is becoming harder and harder to "pull off" an illicit stock flotation as time goes on. There are now a number of agencies at work on behalf of the investing public. The public press (or the most reputably part of it) is awakening to a sense of its responsibility to its readers, and a number of publishers have discovered that to associate in any way with mining frauds is a short-sighted policy. It is likewise highly satisfactory to note the discriminating interest that is being taken by a number of sound brokerage houses in legitimate mining ventures.

ADJURATION
TO
MR. C. M. CAMPBELL.

Dear Mr. Campbell, haste your armour buckle,
For your opponent, Mickle, is a mickle!
Round One is his, you almost take the count
And with your silence his belief will mount
That you are beaten, done completely [illegible]
Your dialectic fame for e'er diminished
Because your choice of sides involves some support
You must by no means take a chance at opposing
So waken, Brother Campbell! [illegible]
Us if you prove a mickle [illegible]

E. C. M.

"Recollections of an English Gold Mine"

I had not known, until I happened to open an old volume of that sterling and long defunct periodical, *Once a Week*, that the gifted and whimiscal George du Maurier had ever had anything to do with mining. Apparently he had, for in *Once a Week*, September 21st., 1861, appears a short story written and illustrated by him and entitled "Recollections of an English Gold Mine."

From internal evidence I gather that du Maurier is the hero of the story himself. Of this, however, I am not sure. In any case, the narrative is written in the first person singular and there are intimate touches throughout that seem to indicate that the story is a transcription from real life.

The story opens in the year 1855, when, according to the author, the gold fever had been imported from Australia into England and was raging with "unmitigated violence." Rumours of rich discoveries in certain parts of England were rife. London was all excitement. Our hero caught the fever, but was cured of it by his hard-headed father. At the same time his father set him up as an analytical chemist, and equipped a laboratory for him quite regardless of expense. All that was needed now was clients.

After a few months of waiting the hoped-for happened. Somebody introduced our hero to somebody else, who, in turn, introduced him to the Chairman of the Victoria Gold and Copper Mine situated near Moleville, in Blankshire. The mine was in a bad way. £6000 had been spent on it without result so far as gold was concerned. There was ample copper, but copper had lost its charm. Two celebrated chemists had never failed to find gold in samples of the ore, but there were no corresponding returns from the amalgamating devices in use at the mine. "There was a mystery about "this which was solved by the matter-of-fact instinct "of my dear papa, in a way so very uncomplimentary "to some person or persons unknown, that I really "think it better not to say anything further on the "subject."

The young man was asked to assay a sample of ore for the Victoria company. This he did, and here is du Maurier's somewhat naïve description of the process of assaying:—"The sample was most conscientiously "analyzed: crushed into fine powder, I recollect, "triturated with quicksilver in a small machine in-"vented by Mr. Perkes, an American ...The quick-"silver was carefully and decorously distilled, and left "a small residuum which was fused with litharge, and "afterwards melted again in a beautiful little white "thing called a cupel; and the result was a most "surprising button of pure gold, sufficiently large in "proportion to the matrix ... to encourage the most "sanguine hopes."

The now enthusiastic assayer reported the good news to the Chairman, but found that the latter was not at all surprised. It was then arranged that the young man pay a professional visit to the mine. His fee, agreed upon after some debate, was at the fabulous rate of a guinea a day and half a guinea for expenses. He travelled to Moleville with the company's mining engineer. "We walked from Moleville to the mine ... " and suddenly the first mine which I, a mining "engineer of some standing, had ever beheld, burst upon my view." There he was left in authority over twenty or thirty "Shaggy, rough-looking miners." The first signs of insubordination were met by our hero "with one or two acts of summary justice (which I "will spare the reader, but which, emanating from me, "caused me unlimited astonishment)."

He found that a large edition of the Perkes amalgamating machine had been "working indefatigably "night and day, and on the very morning I got there, " the last ton was disporting itself in the machine, "impalpably pulverized with mercury, and was running "off with the water in a kind of clear, red mud, "having of course left all its gold behind it." After fining two men half-a-crown apiece for grinning when he took his razor strop out of his carpet bag, (he was a beardless youth), he stopped the Perkes machine, drew off the mercury, put it in a retort, luted on the cover, and "stamped the luting secretly in two places " with a crooked six-pence, to prevent mischief."

The gold obtained proved that the ore averaged about one penny to the ton. The youth informed his employer of this in a laconic note. In reply, the Chairman reproved him for the tone of his letter and requested him to stay on indefinitely for the purpose of conducting further experiments. The young man consented cheerfully to do this. Meanwhile another wonderful amalgamating device, the invention of a retired army officer, had arrived on the scene. "I will "not attempt to describe the marvellous piece of "mechanism which had emanated from the depth of "the military gentleman's consciousness; but merely "state that it turned out to be a perfect Irish bull of " a machine." At this stage of the game the miners themselves began to see the joke. "The miners did not "believe in the mine, and as they perceived that I did "not either, they believed in me to a most flattering "extent. Indeed, I soon got very much attached to "the fellows, and used to tell them long stories about "foreign lands... and enlighten them on various "subjects on which I felt their ignorance to be equal "to, or greater than, my own ... My letters home con-"tained descriptions and sketches of them, and mama "became interested in their spiritual welfare."

The youthful mining expert had the time of his life for about a month. Festive evenings were spent at delightful old inns; pretty girls were flirted with; and he did much entertaining at his own hotel, "with "an elegant hospitality which exalted our jovial good "fellowship into the most sentimental affection towards "the small hours of the night."

But good times were drawing to a close. The directors, with their wives and daughters, decided to pay a visit to the mine. They came. All was prepared for them. Several of the miners had gone so far as to wash their faces. The mine captain had put on a new yellow waistcoat. The military gentleman's machine "revolved on itself in a charmingly symmetrical man-"ner." The visitors arrived. "They inspected every-"thing with the eye of a hawk. They too, since I had "left them, had made themselves thoroughly proficient "in those technical terms without which no science can "ever rest on a solid basis; but occasionally applied "them in a careless manner, I must say."

An hour's inspection so exhausted the party that refreshment was imperative. Hampers were unpacked, champagne flowed, the assayer sang Tyrolese ditties,

and two young ladies warbled "Excelsior." Eventually the assayer was packed into one of the empty hampers and driven to his hotel in state. A warm evening ensued, in the course of which the assayer was given a hint by the Chairman to the effect that it would pay him to speak favorably of the mine. He was further instructed to prepare "a clever matter-of-"fact report." Next morning some of the directors made their breakfast entirely off soda-water. By the time our hero had finished *his* soda-water, the carriages were at the door. It was understood that the assayer was to follow the party to London and bring his report with him.

His good-bye to his men was very affecting. "One "gave me a tobacco pouch, another a short black pipe, "which I determined not to use till age had made my "constitution stronger. The captain presented me "with a small Testament,...even Hodge, who was the "poorest of the poor, pressed upon my acceptance a "beautiful dead snake, which emitted a very powerful "odour."

Next morning he was in London under the paternal roof. A shareholders meeting was to be held in a week's time. He therefore, with his father's assistance, set about compiling a report. This he mailed to the Chairman. It was returned with a suggestion that the addition of a little fiction would do no harm. Very discreetly our assayer wrote back again enclosing the report and stating that he would do justice to the occasion in an *extempore* speech. And he kept his promise. In a shockingly candid impromptu address he said pretty nearly everything that the Chairman did not wish him to say. He touched upon the military gentleman's machine in these words:—"An instru-"ment, in short, which revolved on its axis for nearly "a month, with a persistency that was quite pathetic; "but in spite of its great merit, it was not exactly "calculated to find a mineral which did not exist, and "it failed to do so, probably owing to that very cause." This was enough for the shareholders. Our assayer was paid his fee, the company was wound up, and a new company made handsome dividends from working the mine for copper.

The story concludes:—

"**QUERY**: How did the gold get into the samples?

"**MORAL**: The mysteries of science are inscrutable to the uninitiated mind."

J. C. MURRAY.

MICA IN GUATEMALA

In view of Canada's important position in the production of mica, a U. S. consular report from Guatemala, Central America, is of interest. As a result of development work now in progress, Guatemala, although at present a small producer of mica, may become an important exporter of this mineral. The United States requires four times the mica it produces, and Guatemala should readily find in the United States a market for all that it can export in the future. There are to-day four mines open and operating, all under American control, a fifth mine will be opened within a month or two, and two more mines are expected to be operating before the end of the year. Present production is at the rate of 600 to 1,000 pounds per month, being about 40 per cent. cut mica and 60 per cent. rough trimmed, all of which is being shipped to the United States.

TECHNICAL GRADUATES NEED COMMERCIAL TRAINING

That engineering college graduates are handicapped without a supplementary commercial training is the conclusion of research investigations just completed by Dr. W. F. Rittman and W. F. Reilly, of Carnegie Institute of Technology, Pittsburgh. In the Carnegie Technical Journal, a quarterly publication of the alumni and students of Carnegie Tech, Messrs. Rittman and Reilly present substantial proof of the need of commercial training in Technological college courses.

With the cooperation of the Alumni Office, a study of the present occupations of Carnegie Tech. graduates was made. Of the graduates from 1908 to 1921, the investigations showed that approximately 67 per cent of the total engineering graduates are now engaged in Commercial or Managerial Work. This majority becomes significant in consideration of the fact that "engineering" graduates include a wide range of highly technical fields such as Mechanical, Electrical, Civil, Chemical, Metallurgical, Mining, Sanitary, and Science.

An interesting tabulation in the report shows the following percentages of engineering graduates in all departments who are now in Commercial or Managerial capacities: Mechanical Engineering, 65 per cent; Electrical Engineering, 60 per cent; Civil Engineering, 73 per cent; Chemical Engineering, 59 per cent; Commercial Engineering, 91 per cent; Metallurgical and Mining Engineering, 67 per cent; Sanitary Engineering, 60 per cent; Science, 77 per cent.

One of the two most important generalizations cited by the authors in their report is that "the great majority of graduates use their technical education as a means of getting into commercial or managerial work. It is believed that a similar study of the activities of the graduates of other technical institutions corresponding to Carnegie Institute of Technology would show this same order of classification, which seems to be natural and in conformity with the trend of the times."

Carnegie Tech. was one of the first technical institutions to incorporate a separate Commercial Engineering Course in its College of Engineering. Its foresight in anticipating the demands of industry for college graduates with supplementary business training is apparently substantiated by the research investigations of Messrs. Rittman and Reilly.

With the loss of coal lands in Silesia and when held by France on the product of the Ruhr basin, Germany's fuel resources are taxed to the utmost. One of her most important resources is lignite, or brown coal, which is very extensively used. Much of it is used in the raw form as domestic fuel. A growing proportion is, however, being treated by distillation to give gas, oils of various sorts and coke of a good quality, which is used in the manufacture of [illegible] comes from the retorts, without briquetting. Most of the lignite beds contain only a very small amount of [illegible]. Many are worked as quarries and [illegible]

The Mattawin Iron Range

A Description of its Eastern End, the character of the Ore, and its Possible Utilization

By F. HILLE, M.E.

When a number of years ago a Swedish savant endeavoured to give us, in an interesting statistical paper, a summary of what iron ore reserves the world in general, and each nation in particular, possesses, a certain chill of embarrassment went through the industrial world when it read and studied the comparatively small amount that each country was said to have at its disposal of ore of such grades as could be used economically directly from the mines to the smelters. Each nation, especially the large industrial and commercial ones, looked eagerly about and took stock of what tonnage they had still available for present and future use.

The United States Geological Survey busied itself, figured and estimated every known iron range and deposit of the land; the result was a considerable amount on which they claimed the American people could depend. However, in these figures were included not only the so-called high-grade ores, ranging from 55% iron content and over, but also those of much lower percentage. Of course that was, from a patriotic point of view, perhaps laudable, but considered from the view point of political economy, not very practical, because it lulled the nation into a sense of security which, from the present industrial standpoint, was not exactly justifiable. This question and the argument that followed did bear fruit to the advantage of everyone concerned, because attention was then paid, not only to the higher grade ores, but also to such ores as appeared even a short time ago too inferior for present practicable use. This move had another good result, in that men's ingenuity was brought into play and new processes invented by which the immense quantities of low-grade ores, of almost every composition and natural characteristics, were brought into use, but principally the low-grade magnetites, owing to their ready adaptability to a process of separation of their iron particles from their impurities. The magnetic properties of their iron particles gave a ready clue to the simplest and cheapest method by which they could be treated.

Canada's Vast Supply of Magnetite

Canada, especially, is well supplied with this class of ore, and shares with Sweden and Norway the first rank as to quantity. Sweden and Norway have beaten us in the race for practical use of these ores and have been, on this account, vastly benefitted, not only by their utilization in their own industries, but by bringing the improved ores into the market in the European iron centres, where they are established now as a "sine qua non."

In the last few years we have, here on this continent, commenced at last to consider more seriously our own resources of this variety of ore and have begun to make use of this, one our principal assets. Here in Canada, however, we have not yet progressed to the degree to which the lack of other iron ores should have compelled us.

Now, there is no denying that the smelting of high-grade ores is much more economical than the smelting of those of lower grade, especially, if the latter have to be transported long distances from the mines to the smelters. If, then, the processes that produce a high-grade ore such as concentrates or briquettes are economical, that is if the extra value of the higher product will balance the transportation and the additional smelting expenses of the run-of-mine ores, then this of itself would justify the erection of plants in which to improve these low-grade ores. The processes for improving this class of ore are now so well established, and the magnetic ores of Western Ontario are so amenable to them, that only lack of experience or sheer negligence would cause such enterprises to fail.

The Mattawin Range

There are many localities in Western Ontario where these ores occur, but I shall confine myself in this report exclusively to a locality that offers so many advantages that I have chosen it as a prospective starting point for an industry that will be a benefit, not only to this country, but to all those that are deficient in iron ore resources, and not only for the present, but also for coming generations.

The locality to which I refer is a part of the so-called Mattawin Iron Range. The magnetite deposits occurring there form an almost compact mass of ore, over 1,400 feet in width and several miles in length, with a depth that the diamond drill had not penetrated at 1,000 feet. According to stratigraphical data, the full depth would be 11,200 feet, and our Geological Survey came to almost the same conclusion, estimating the depth to be between 10,000 and 12,000 feet. However, I like to be conservative, and desire that my readers may find my assertions more than borne out by the proven facts. Let us, therefore, halve these figures and take 5,000 feet as the depth, and even then by calculating the cubic contents of these deposits, and multiplying them by the specific gravity of the ore, we arrive at a figure that staggers the imagination. I hold that it is a duty of our iron masters to bring into industrial use this ore, before the present resources of high-grade ore, which are comparatively meagre, shall have been exhausted.

The province of Ontario alone is able to supply much more than the full requirement of iron ore for Canada. It remains but to "take the bull by the horns," develop the deposits, concentrate and agglomerate the ores, and ship them to furnaces already ready and willing to accept such high-grade material.

Situation and Physical Features of Mattawin Range

The deposit, to which I have made reference above, commences in the neighbourhood of the 48 mile post west of Port Arthur on the Canadian National Railway, and continues almost uninterrupted to the 51 mile post, a distance of about three miles, embracing an area of about 960 acres. The locality is easy of access because the above named railway passes right through the properties. They are therefore, not farther from a harbour on Lake Superior than the distance named. The highest elevation of the hills, upon

which the greater bulk of the ore is situated, is from 300 to 350 feet above the railway. This is true in general from the 49 miles post to the 51 mile post and westward; from the 49 mile post east for one mile, a valley intervenes, and then the hills resume.

Water for milling purposes is available by gravity from a number of small streams that cross the property. Water power to the extent of 1,000 to 1,500 horsepower is available on the Mattawin River close to the property, and a larger power is available on the Shebandawan River, to the northwest.

Geology of the Range

The rocks constituting the Mattawin Range are a remnant of our earth's first crust, laid down in Keewatin times, now folded into anticlines and synclines and metamorphosed into chlorite, hornblende and micaceous schists. In pre-Cambrian times eruptive rocks intruded the foregoing, these being principally diorites and gabbros and in places diabase, the youngest rock of the region.

These pre-Cambrian intrusive rocks had a certain influence upon the ore deposits, which were deposited as carbonates, but were changed by the heat of the eruptive rocks, according to the intensity of the heat that reached the ores, either into magnetite or martite, or into a mixture of hematite and magnetite, as is the case in some deposits along the Shebandowan River. The principal intrusion of pre-Cambrian rocks occurred north of the Mattawin River along a line of weakness.

Character of the Ore

Under this head we have to consider the special characteristics of the ore, a study of which is necessary for its present as well as future treatment.

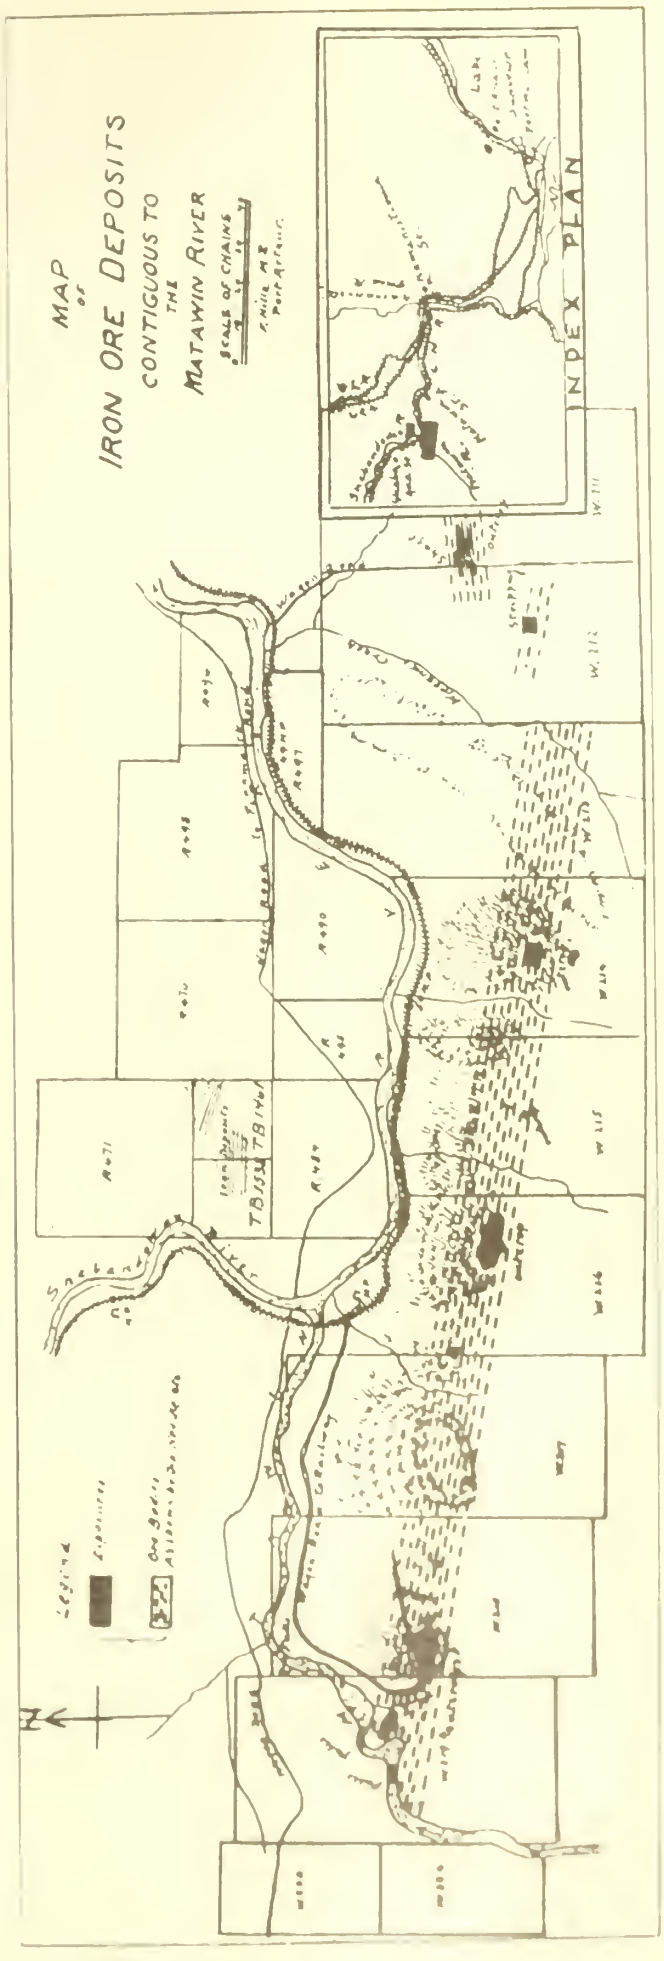
Exploration has shown that the ore on claims W. 211, 212, 213, 214, 215 and 216 (see accompanying map) is magnetite of two principal compositions.

1.—One of banded structure, that is, one in which bands of jasper alternate with bands of high grade magnetite.

2.—Second, in which the impurities (mainly silica) and iron oxide particles are intimately mixed.

The ores of the first class are solid and compact, and only where a lateral pressure was exerted upon them did they receive a somewhat schistose structure, and whenever this is so, the bands of iron and jasper are easily detached from each other by crushing. The iron bands show usually a steel blue color and are rich in iron, often from 58 to 60% and more. The jasper bands, on the other hand, show different colors in different localities, bluish and grey being prevalent, a bright red at a few places, and, where this is the case, the ore has usually undergone intense pressure and heat, the latter being sometimes so great that the ore was converted into a viscous mass, that shows how by bands twisted in every conceivable shape and figure. This interesting phenomenon can be well observed on a large deposit on W. 211. The magnetism of this ore as shown by a survey is remarkable and the change from positive into negative is intense and abrupt. It is a very fine ore for concentration.

The average iron content of the banded ore lies between 35 and 45 per cent. A typical sample of this class of ore, coming from the north side of the Mattawin River, from the same deposit that also crops out on claims T. B. 1538 and 1461, gave the following result:



Iron	38.90%
Silica	44. %
Phosphorus	0.13%
Sulphur	0.03%

Its iron bands alone gave:

Iron	60.60%
Silica	15.26%
Phosphorus	0.18%
Sulphur	0.05%

The second class of ore is as massive as the former just described, but instead of being banded, the impurities (mainly silica) are intimately mixed with the iron oxide particles. To separate these it is necessary to break and grind this ore to such a fineness as to liberate them from each other.

The average iron content of this ore lies between 30 and 38%; some deposits will give even a higher percentage. The western outcrops on claim W. 216 will average about 36%. The southern part on W. 214 and 215 will run about the same, especially when taken from pits or other points below the surface. If, however, the sample is taken from the surface, we find an impoverished ore from which a part of the iron has been dissolved out by moisture in combination with humic acids derived from the overlying vegetable matter. This loss amounts sometimes to 5 to 10% iron; however, one shot into the surface will change these conditions, as we find to be the case with the same deposit on the east side of W. 216 where, owing to the dissolution of the iron, the silica was increased by nearly 10%. I draw special attention to this occurrence, so that every phase of the nature of these iron deposits may be rightly understood.

To view the ore from every point I shall now cite some general analysis of the Mattawin ores and some partial tests.

The first is a general analysis of a surface ore from the large outcrop on the eastern side of W. 216; the second is a complete test of that portion situated a little farther west, where the ore was taken from a shallow pit.

	No. 1 (Surface)	No. 2 (Pit)
FeO	12.28%	13.39%
Fe_2O_3	21.70%	34.90%
Iron	24.73%	34.82%
FeS_2	0.33%	0.18%
Sulph.	0.18%	0.10%
MnO	0.21%	0.70%
Mang.	0.16%	0.54%
Al_2O_3	7.93%	3.10%
CaO	0.87%	1.27%
Mg.O	2.65%	2.36%
P_2O_5	0.32%	0.32%
Phosph.	0.14%	0.14%
SiO_2	51.36%	41.46%
TiO_2	0.03%	Trace
Titan.	0.02%	Trace
H_2O & CO_2	1.35%	2.87%
Na_2O & K_2O	0.97%	.....

The average of six samples taken out of some pits gave metallic iron 36.06%. Surface ore from the same place contained 24.82% metallic iron. This difference explains what I said respecting surface and pit ore.

It may be of interest to note here that the iron contents of the deposit from which No. 2 sample was taken did not decrease at depth, but, on the contrary, it increased nearly four points, since an average of 180 feet of diamond-drill core, coming from 850 feet in depth, gave 38.68% metallic iron. However, it is easily understood that, over so large an area as is covered by the ore deposit, there are places where the ore shows a lower iron content, but this is balanced by others where the ore is above the general average, as is the case with the deposit on W. 211, 214 and T. B. 1538 and 1461 and others.

I now add a complete list of all the analyses I made on Mattawin ores in the course of a number of years. The special place from where each individual sample came was not always given me, but I know positively that they came from within the limits of the deposit that is the subject of this article.

LIST OF ANALYSES

Assay No.	Iron		
1985	44.69%	2095	38.75
1986	35.64	2096	26.80

* Diamond drill core.

** Core from 850 ft. depth average of 180 feet.

*** Core depth not stated.

Concentration Tests

I have made a few concentrating tests of the foregoing ore. For the first I took a low grade surface ore, of the following composition, which gave concentrates, as shown in the second column:

	Raw Ore	Concentrate
Iron	24.16%	66.50%
Silica	52.07%	6.50
Phosphorus	0.14	0.008
Sulphur	0.06	0.002

This was an ore in which the iron and impurities were intimately mixed together, and yet the result was very satisfactory.

The second test was made with a higher grade of banded ore from T. B. 1461: a partial test showed the following ingredients:

Iron	38.90%
Silica	34.
Phosphorus	0.13
Sulphur	0.03

The concentrates of this ore were produced in three grades of finess, namely:—

6 parts were	60 mesh
1 part was	80 mesh
1 part was	100-200 mesh

The 60 mesh concentrate contained:

Iron	65.10%
Silica	6.50
Phosphorus	0.04

The 80 mesh concentrate contained:

Iron	67.50
Silica	4.50
Phosphorus	0.04

The 100-200 mesh concentrate contained:

Iron	69.80
Silica	2.57
Phosphorus	9.09

These few tests show that the ore has excellent properties for concentration: in every instance a high-grade Bessemer product resulted, high in iron and low in phosphorus, with hardly any sulphur. I could add the results of a few more such tests, but it would not increase the knowledge as to the amenability of the ore to concentration.

Mineralogical Characteristics of the Ore

By the two general analyses I gave above, the reader will have got a fair idea of what the run-of-mine ore consists. The principal impurity of the ore is silica, with some manganese. This latter we cannot call an impurity as it does a certain service in the furnace product. Sulphur, on the other hand, we must call an impurity, and one of the most objectionable, if it is in too large quantities in the ore; but, fortunately, the sulphide of iron in the Mattawin ores is a negligible quantity, not only on account of its insignificant amount, but also owing to the readiness with which it is eliminated by the concentration and briquetting or agglomeration process.

Somewhat different is the occurrence of the phosphorus, because sometimes it is a constituent of the iron oxide particles. Sometimes it is a mixture of a certain phosphor ore, usually apatite, and if in this state it is easily eliminated. Sometimes it is also an infiltrated product, derived through the decomposition of vegetable matter; where this is the case it soon will disappear, usually a few feet below the surface. I have found, however, that it exists in the great bulk of the ore as an independent mineral, as we may notice in the few concentrating tests I have given.

The alumina, lime and magnesia and a certain amount of the silica, are not exactly impurities, because they play various roles in the smelting process; but if left in the concentrate they would reduce the percentage of the iron. However, these disappear in the milling process.

Commercial Value of the Ore

The average grade of our Mattawin ores, high and low, as shown in the above list, is 37.72% metallic iron. This is higher than the ores which most of the iron ore concentrating plants in Europe and the newer plants in America are treating, and, I may venture to say, few, if any, possess equal facilities for mining, concentrating and shipping. Owing to the size and position of the deposits, open air mining can be substituted for underground work.

Pumping expenses would be very small, owing to the nearness of the water in large quantity; the concentrating process could be carried on automatically, thus saving labour. What wood and timber is necessary for heating and building is found on the land. The shipping facilities could not be better, because the railway skirts the deposits, and the ground is favourable for building of the railway yards, stock-bins, etc., that the handling of the ore and concentrate may be made as convenient as desired. I may again remark that the ore deposits are so large that it depends only on the capital available and the demand of the market what amount of ore is mined. That the demand for pure, high-grade ore is growing is evident, owing to the diminishing supply of the high-grade mines, and owing to the steady increase in demand for high class steels: there need, therefore, be no apprehension as regards demand.

Now, in summarizing what I have just mentioned, it should be readily understood that the value of these ores and their products may be expected to rise from year to year, and that, by the daily practice in handling these ores and converting them into marketable shape, the cost of production should diminish, especially with a constant increase of the amount worked daily.

The Concentration Process

In any discussion of magnetic concentration and the subsequent agglomeration of the fine particles of ore, due credit should be given that pioneer, Dr. Grondal. The "Grondal Magnetic Separation Process" is still in commercial use in various parts of the world, though parts of the mechanism he devised tend to be superseded by newer and more economical forms of machinery. Dr. Grondal's original arrangement of plant was simple, consisting of crushers, followed by magnetic cobbing machines, ball mills, tube mills, classifiers, magnetic concentrating machines, briquetting presses and sintering kilns. This has been somewhat modified in the new plant at Babbitt, Minnesota, with a reduction in working costs, but the result is a similar most desirable material for the blast furnace. [These plants have already been described fully on numerous occasions, and the description will not be repeated here.]

The fine concentrates are baked by these processes to a solid mass, that constitutes now a hematite ore, for the former magnetite is changed from a ferro-ferric oxide into a ferric ore, and is sent in this state to the

smelters, with a metallic iron content of from 65 to 68% containing 4 to 5% silica, with little or no phosphorus, and no sulphur.

These briquettes, or sintered ore masses, have attracted the attention of every furnace man, because the advantages over almost any natural ore are considerable. Owing to their porosity they are more easily reduced in the furnaces, which tends to a saving of fuel and time, in comparison with the natural ore. The saving of fuel may reach 15 to 17%, and there is saved also a certain amount of flux, as well as a smaller amount of slag. Also there is no cooling of the furnace through moisture in the ore.

The absence of sulphur and presence of only an insignificant amount of phosphorus is an additional advantage.

Prospective Concentration Plant

The situation of the plant should be as close to the mines as circumstances will permit. There are a number of places on the Mattawin range that offer natural advantages for building a plant, either as a gravity plant, or on a level plan, or a combination of both. Of course there are several other matters to be considered, for instance, the location for railway sidings, loading and unloading yards, station, etc. Further, the location for the worker's cottages, water and wood or other fuel supply, and last, but not least, convenient delivery of the ore into the plant.

It is mainly by considering the experience gained by established plants, that we can learn and draw our lessons as to costs of running and of establishing such enterprises. If we adapt these to our own local conditions and usages, we may arrive at a fair computation of what the cost of such a plant would be. However, I shall at this juncture not go into details, but will state here only a lump sum, and leave it rather to experts in this line to do this when the right time arrives.

The cost of a plant that treats 3,000 tons of raw ore would be in the neighbourhood of $600,000. This refers only to the building of the concentrating mill, mining plant, yards, cottages for workmen and working capital; other expenses connected with the undertaking are not included in the above sum.

To give a detailed estimate of every item that would come under the above heading would overstep the intent of this paper. I shall condense the estimate into a few figures that will serve the same purpose for the present.

We have to keep in mind that we wish to mine and treat 3,000 tons per day of an average iron content of about 35%. This would give us approximately 1,560 tons of briquettes of an iron content of 68%; the ratio of crude ore to briquette would be 1.92 to 1.

The cost of mining 1 ton of ore is	$1.013
The cost of milling 1 ton of ore is	0.820
	1.833
The cost of mining (per ton of briquettes)	1.948
The cost of 1 ton, briquetting and gen. exp.	1.576
Total cost of 1 ton briquettes	$3.52
Cost per ton of briquettes laid down in Port Arthur	4.02
Cost per ton of briquettes laid down Lake Erie ports	5.22
The base price of 55% Old Range Bessemer	6.45
The value per ton of 68% briquette	7.62
Margin of profit per ton in Port Arthur	3.60
Margin of profit per ton in Lake Erie ports	2.40

Daily profit, $3,744 and $5.616 respectively.

Of course the above figures relate to a time when the whole enterprise is in a smooth working condition, for the expenses incidental to a new industry are, at the beginning, usually unexpectedly and disproportionately high, until practical experience has taken the place of theory and experimentation.

WHY COAL IS BEING INVESIGATED

The recent revival of building operations in our cities everywhere affords visual evidence of the extent to which the huge steam shovel with its pile of coal has taken the place of human labor in excavating for the modern building. Nor is the contribution of coal in construction work all visible, for the structural materials themselves are largely the product of coal burned at mine, quarry, and furnace, at brick or cement kiln, and at the steel plant. This explains how figures recently presented before the United States Coal Commission show that about one-third of the weight of a fireproof office building as today constructed represents the tonnage of coal that was consumed in the preparation of the building materials.

It is a far cry from steel and bricks to the fruit that comes to our breakfast table, but coal is no less a component part of that fruit. The cantaloupe that is transported in a refrigerator car from an Arizona ranch to a Boston home represents an expediture of nearly two pounds of coal, or its equivalent in oil or water power, in the form of ice and locomotive fuel. And, at another season, the orange from California grove appears on the same breakfast table in Boston only by reason of a similar expenditure of over half a pound of coal. Thus, whether we get it in the form of luxuries, which so soon come to be regarded as necessities, or in the form of raw materials of industry, coal has become an essential item in the daily life of the people.

One fact, therefore, that the United States Coal Commission might feel that it does not need to establish is that coal is a necessity of modern life and the coal trade might well see in the present inquiry some ground for hoping for more stable conditions in the future. Yet, "Why pick on coal?" is the head-line of an editorial in a leading coal journal commenting on recent activities of Federal, State, and municipal agencies, and suggesting eggs, cabbages, apples, and Wilton rugs as other essential products that might not be any better able than coal to withstand the "dazzling white light of legislative research."

The long list of Congressional and other inquiries directed specifically toward the coal industry surely justifies the coal trade in regarding itself as the most "generally be-diviled business organization on the face of the earth, excepting possibly the railroads." However, the increasing public interest in the subject of coal, even though chiefly reflected in public investigation, should be regarded as proof of an increasing realization of what coal means in the world of today.

At the meeting of the American Association for the Advancement of Science to be held in Boston during Christmas week, Mr. J. B. Tyrrell, one of the retiring Vice Presidents, will give an address before the Engineering Section on "Mining in Canada."

LETTERS FROM READERS

Optimistic View of B. C. Mining

The Editor, Canadian Mining Journal.

Sir,

Mr. C. M. Campbell's cheerful letter, which appeared in your issue of November 3, should have been timed to appear just before Christmas, and thus brings its glad tidings of comfort and joy to his brethern in the mining profession for the festive season.

As Mr. Campbell states, one can prove pretty nearly anything one wants to by statistics to one's own satisfaction. If the optimists of the mining profession have garbled statistics to prove their points, surely Mr. Campbell is not entirely innocent of a similar offence to prove his. He has "mussed up" a piece of perfectly good plotting-paper with curves—rather angular ones—to illustrate the growth of various industries in Canada during the last twenty years, and particularly to show that the manufacturing and agricultural industries have entirely out-raced those of mining, fishing, and forestry; but, so far as I can see, he has succeeded only in showing how kindly the Canadian manufacturer took to the gentle art of profiteering at the very commencement of the war and that, though the farmer took a year to get into into his stride, he proved an apt pulpil. If these curves had been brought to date, it would have been found that the manufacturers and agriculturists are little, if any, better off as regards production and certainly as regards profits of production than they were at the beginning of the war. All of which goes to show that statistics obtained during war-time are fairly useless during periods of peace.

The false impressions given by the curves do not end here, however. The curve that shows the output of the manufactories does not show the cost of the raw material required to produce this output, nor that a very large proportion of this raw material is imported. It fails to show, too, that the products of the factories have been, and are, fostered and pampered by a high protective tariff, while the mining industry, in most instances, has to combat foreign competition unprotected.

In another table Mr Campbell points derisively, among other items, to ten and a quarter million dollars paid in 1920 for manufactured brass and copper goods mostly rods and bars that were imported into Canada; but he fails to mention that Canada produces more copper and zinc than it can use, or that there is a copper refinery and a brass and copper rod mill idle at Trail, B. C., which if given a reasonable period of protection would be capable of turning out all the copper and brass rods and bars that Canada needs. It has not been given a period of protection, however, because there would have been a hue and cry from the manufacturers of electrical machinery and the drawers of wire—pap fed concerns that Mr. Campbell eulogizes—and from electrical transportation, telephone, and telegraph concerns, which together control a far greater number of votes than the copper producers.

In his previous letter on this subject, Mr. Campbell stated that there had not been an outstanding mineral discovery in British Columbia in a decade, and I should have thought more of the seriousness of his present letter had he referred to the development of the Premier mine. Though the actual mine was known and worked before, the immense ore-bodies at the Sullivan has been discovered only within the last ten years, as has likewise the new ore-shoot at the old Slocan Star mine.

Mr Campbell avers that our coal reserve has been over estimated, (probably it has,—Mr. J. D. Mackenzie, who has just revised the figures for Vancouver Island, shows that in this instance it has, at any rate), and that there is need for conservation of coal. There *is* conservation of our coal. The coal miners and laborers, by their exhorbitant demands in the way of wages, and the operators and dealers, by their extortionate prices, are taking care of that. They have forced the coal consumers to turn to fuel oil, wood, and electricity generated by water power. No one uses coal in British Columbia today if it is at all possible to use anything else.

Fortunately few people view the condition of the mining industry in British Columbia from Mr. Campbell's dismal outlook. The Granby company, Mr. Campbell's principal, is looking for fresh fields to conquer, and is exploring a number of properties in the Portland Canal division It is just completing a large reservior, at a cost of some $400,000, which will render it independent of fuel for power purposes. The Britannia company has nearly completed its new mill, and has made a contract with the British Columbia Electric Railway Company to provide power to operate it. This mill will cost in the neighborhood of a million dollars, and will be the largest copper ore concentrator in the British Empire. The Consolidated M and S Co. is spending something like the same amount on a new mill at its Sullivan mine, and has contracted with its East Kootenay Power Company for electricity to operate it. A New York syndicate has bonded the Le Roi No. 2 mine, at Rossland, it is said for a million and a half, and dozens of United States concerns are pouring money into the development and exploration of abandoned mines and of prospects in the Slocan, Portland Canal, Hazelton district, and other parts of British Columbia. These people are showing their optimism in the future of the mining industry of this Province in a practical way. "By their works ye shall know them."

Victoria, B. C. F. H. Mason

TARIFF AFFECTS METAL MARKET

Sufficient time has elapsed since the enactment of the new United States tariff law to enable a survey of some of the immediate effects of the new rates. In certain items in the metal group the discounting of the new tariff began a week or two before the bill was signed. In others, such discounting began after the bill was signed.

Ferrotungsten has advanced from 61 to 94 cents a pound contained in about two months; tungsten concentrates from $3. a unit to $7.50 a unit. Purchases for importation have ceased, at least temporarily. Fifty per cent ferrosilicon has advanced in price from $55 to $75, delivered. Importation of this material has ceased.

Before the tariff was enacted, 4 to 6 per cent. carbon ferrochrome was quoted 12 cents a pound contained by domestic makers and 10 cents by importers. The importers have advanced their price to 12 cents duty paid, but domestic alloy still can be bought at 12 cents. Manganese ore purchases were heavy prior to the signing of the bill, subsequently they have been lacking. The market now is nominally quoted at the old price plus the duty, in other words, 29 cents and 22 cents, totalling 51 cents.

The duty on pig lead was advanced from 2½ per cent ad valorem to 2 1/8 cents specific. The demand in this country has been so heavy and domestic production has turned so slowly that the American market has discounted the entire increase in duty in the face of a higher world market and now is drawing supplies of Mexican lead on a large scale.

The duty on zinc was increased from 15 per cent ad valorem to 1 3/4 cents a pound specific. While this has given increased production to the same industry, the shortage in Europe has become so acute that there have been

heavy purchases of American zinc for export to Great Britain and the Continent. Prices both here and in London have risen to the highest levels in two years.

While no duty was imposed on copper, fabricated products have been given a protection, ranging from 2 1-8 cents on sheets and rods to 7 cents on tubes and 12 cents on brass angles and channels. Foreign competition has not been an important factor in the market and the imposition of the duties has had no immediate market effect. The antimony market discounted the full increase in the duty from 10 per cent ad valorem to 2 cents a pound specific prior to the signing of the bill and since then has eased off.

The domestic aluminum producer has made two price advances totalling 3 cents a pound since the law became effective, increasing ingot aluminum duties from 2 to 5 cents a pound. In other words the full increase in duty has been met by the market. Foreign aluminum in good sized tonnages has been sold for importation, for 1923 delivery.

In general the tariff has been an important factor in the metal markets though much of its first effects have been discounted, as was to be expected.—from "Iron Ore," Ishpeming.

Advance Summary of Coal Statistics

The mining Branch of the Dominion Bureau of Statistics has issued an advance summary of coal statistics for Canada showing the imports of anthracite and bituminous coal by grades and by provinces during the first eleven months of the present calendar year with comparative figures showing the average imports during the same period in the three years 1919-20-21. Exports of Canadian coal are also shown.

TABLE 1, IMPORTS OF ANTHRACITE COAL BY GRADES & PROVINCES

TABLE 3, EXPORTS OF CANADIAN COAL

	(1) Total for Year to date 1922	(2) 3-Yr. Aver. for Period 1919-20-21	(3) % of (1) to (2)
Eastern Canada	685,313	995,940	69.
Western Canada	967,027	1,031,419	94.
TOTAL	1,652,340	2,027,359	82.

Note: Included in the above amounts are the following quantities of coal imported from Great Britain:

a	900 tons	e	16,404 tons	i	115,595 tons
b	102,879 tons	f	3,712 tons	j	3,267 tons
c	9,858 tons	g	3,217 tons	k	1,999 tons
d	3,965 tons	h	345,712 tons	l	14,052 tons

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

THE NINE MONTHS' RECORD.— The output of the metalliferous mines and smelters for the Province of Ontario for the nine months ending September 30th, amounted to $27,000,000 as compared with $21,000,000 for the corresponding period of the previous year. The principal increases were shown by gold, silver and cobalt oxide, while decreases were shown in the production of metallic nickel and pig iron. Production of gold during the third quarter was at the rate of $22,000,000 a year, and the Department of Mines states that the outlook for gold mining never before appeared to be better. The increase in silver is partly accounted for by the production from south Lorrain. The principal producers of silver were:—

Nipissing	2,960,000	ounces
Mining Corp.	1,289,000	"
O'Brien	884,000	"
Coniagas	827,000	"
Keeley	540,000	"

The gold producers were:—

Hollinger	$9,222,000
Dome	3,063,000
McIntyre	1,506,000
Wright-Hargraves	606,000
Teck Hughes	460,000
Lake Shore	393,000
Kirkland Gold	175,000
Kirk. Lake Prop.	70,000

The total tonnage treated by the gold mines was 1,671,000 tons and the average grade of all ore treated was $9.31 a ton. In Porcupine the Dome, with an average of $11.03, was the highest, while in Kirkland the Lake Shore had the highest heads of $20.54, with Kirkland Proprietary, $6.29, the lowest.

PORCUPINE.— The Night Hawk Peninsular property is offering to the public 300,000 shares of stock at $1.00 par. The capital of the company is $5,000,000 in $1.00 shares, of which 4,300,000 shares have already been issued. With the proceeds of the present issue the company will have $600,000 in cash and 400,000 shares of stock in the treasury, which will be used to continue underground development work and provide funds for the construction of a 200-ton milling plant. The property is considered to be a very promising one and ore reserves, to a depth of 300 feet, are estimated at 133,000 tons of $12.00 ore. — The Paymaster has succeeded in finding some more pockets of extremely rich ore. This ore is as rich as anything ever found in Ontario, and while the quantity is small the value will be considerable. The Dome regular quarterly dividend of 50 cents a share has been declared, payable January 20th. Directors officially announce that by next July arrangements should be completed whereby the shares will be of no par value, and four shares of new stock will be given for each of the present shares. They also state that by that time the present stock will be on a $4.00 dividend basis, which will be equivalent to $1.00 a year on the new stock. In order to insure a continuance of these dividends a fund of $1,000,000 has been created which will be added to from time to time until a full year's dividends is held in reserve. The financial statement of the company shows Cash on hand of $1,240,000 and Bonds amounting to $1,464,385. — The "Two in One" Mining Company, which owns 160 acres East of the Edwards property, have decided to diamond drill.

MORE POWER PROMISED.— The Northern Canada Power Company has decided to proceed with further power installations, calling for an expenditure of $1,000,000, which will provide an additional 4000 h.p. It is expected that the Sturgeon Falls power will be available before the end of January. The company is also considering the diversion of the Grassey River, which would given an additional 3000 h.p.

KIRKLAND.— The Lake Shore is dewatering the 600-foot level and is preparing to sink to 800 feet. A larger compressor has been installed and a new hoist of greater capacity has been ordered; larger crushers will also be installed at the shaft, and new buildings are being put up. This is all preparatory to increasing the milling capacity, work on which should be started before the middle of next year. The directors announced some time ago that mill extensions would not be started until the veins had been proven to a depth of 800 feet, which level should be reached by about the first of April. —A quarterly dividend of 2½ per cent., payable January 2nd, has been declared by the Wright-Hargreaves. —November production of the Teck-Hughes is understood to be very much less than September, which was a record month in the history of the company, with an output valued at $118,000. November production is understood to be about $40,000. Indications are that production for 1922 will amount to over $600,000, as compared with $322,000 in 1921. — Conditions at the Kirkland Gold are somewhat better than previously, and the company now has a considerable tonnage of ore ahead of the mill requirement. The average for the first nine months of the present year was $6.47 per ton, which does not leave much margin of profit, particularly as development costs are heavy, and shaft sinking during the present year has amounted to approximately 500 feet. It is believed, however, that results for the year will show small profit.

THE SILVER MINES.— During the month of November the Nipissing produced 327,000 ounces of silver of an estimated net value of $212,000, and shipped bullion of estimated net value of $165,000. The low grade mill treated 6,987 tons, of approximately 50- ounce ore, and the high-grade plant treated 241 tons. The refinery shipped 252,034 ounces. The production and value for 1922 should be in excess of the year 1921. For the first eleven months of the year the production was 2,912,000 ounces, as compared with 3,111,000 ounces for the full year of 1921, while the value of the 11 months' production is $1,989,000, as compared with $2,189,000 for the preceeding 12 months. It is understood that the cash surplus amounts to about $1,000,000. — The Castle Trethewey, in Gowganda, has decided to build a small mill, plans for which are being drawn by the McIntyre engineers. The Kerr Lake has declared the regular quarterly dividend of 12½ cents a share, payable January 15th, to holders of record January 2nd.

— Another discovery has been made on the Frontier property in South Lorrain, which is owned by the Mining Corporation. This discovery is on the Woods vein, not far from the Keeley line, and is several hundred feet from the main works of the Frontier. The vein is of very high-grade, and in one place is 24 inches wide.

NOVA SCOTIA

Collieries to Work Double Shift.— The Cape Breton collieries will be so active during the winter months that some of them will be placed on double shift. This shows a great improvement in the coal trade over last year, and instead of months of labor agitation and industrial unrest Cape Breton will enjoy business prosperity.

"Red" Tactics Condemned.— That some locals of the United Mine Workers in Nova Scotia are refusing to pay dues while the "red" executive holds office, and that another local is attaching the communist sentiments of the labor paper, is proof enough that the heart of Nova Scotia miners is true to the principals that their fathers have upheld for generations past.

Accidental Death, and Threat of Strike.— An inquiry was held by the chairman of the Workmen's Compensation Board into the death of a miner who was killed and found lying on one of the mine haulage roads. The evidence showed that the man had violated section 77 of the Mines Regulation Act, which states that "no persons or persons but those whose duties take them on haulage roads shall ride on trips or boxes." This man had no duties in such a place. The Compensation Board refused compensation to the relatives of the deceased.

The United Mine Workers held a meeting and decided that compensation must be paid or all the miners, including pumpmen and maintenance men, would be called out. Without making any attempt to have the matter settled, and without trying to show just cause for the payment of compensation, without, indeed, trying anything but a flourish of the "big stick" a threat of strike was made. Labor men of any standing usually exhaust every means to a settlement before a resort to the strike is considered, and it is surely a sign of want of intellect when there is no way but one found to settle disputes. At any rate, what has the Coal Company to do with deciding a case of compensation? Some day, before long, leaders who advise their followers to use such extreme measures as the threat of strike and starvation as a remedy for disputes that are not properly industrial will be returned to the ranks.

The Benefit of Co-operation.— For years strenuous efforts were made by leaders in high places to bring about an amicable understanding between the Nova Scotia Steel and the Dominion Coal Companies on the coal lease boundary question. The output of the two largest collieries at Sydney Mines had been much affected by the division of control, and the Scotia company stated that they required certain metallurgical coal that could only be had by permission to work part of the Dominion company's areas. This permission was given, but under conditions that were rather one-sided.

With the formation of the British Empire Steel Corporation the boundary line dispute has disappeared forever. The output of the Sydney Mines collieries has increased and the costs have fallen. Other charges made were calculated to put the coal industry of the district on a paying basis and to give steady employment to the mine workers. This policy is succeeding fairly well, and with the hearty co-operation of the workmen the cost of mining problems is being solved.

Centralization in Steel Plant.— The attention paid to the development of the coal mines has led rather to the neglect of the steel-making departments, and for more than two years the steel works at Sydney Mines has been quiet. Recent charges by which a number of the clerical staff and machine shop men were transfered to Sydney aroused suspicion, and an agitation was set afoot against the methods of the new corporation. This is little reason for such an outcry, for it is quite natural that the amalgamation of the two former companies should lead to centralization of both shops and executive offices.

Workmen have been loud in their criticism of alleged excessive overhead charges, due to excessive competition between the two former companies. Now they fail to appreciate the good effects that results from the removal of this rivalry. They cannot see that economies in the mining of coal were the first consideration, without which the steel industry would die a natural death. It may be that under the recent trade conditions the coal mines and steel mills could not both be kept running. If that was the case, and if the operation of the coal mines was profitable, than it is obvious that both should not be run, at a loss.

The British Empire Steel Corporation is getting down to an economical basis as rapidly as is possible. In doing this large savings have been effected, and steadier employment is resulting gradually. Sydney Mines will soon share in the general prosperity.

Montreal Market Regained.— A long step forward was made this year towards regaining the coal trade of the Montreal district, lost to the Americans during the war-time. 1,600,000 tons of Nova Scotia coal reached the Montreal market this year. That this could be done in spite of labor agitation extending over a period of ten months, and in the face of keen competition of American mines during the early part of the year, is very encouraging. The output for the year will be less than in 1921, but it is felt that the success gained in the St. Lawrence trade points to an increased output next year.

Coal of Good Quality.— There was never a time in the history of the Dominion Coal Company when

greater efforts were made to place coal of good quality on the market and to meet the demand of the public for a good product, than at present. The method of undercutting the coal has been changed in several of the collieries to ensure clean and large coal. The transportation, cleaning and assorting, screening and loading of the coal into cars are being improved daily, and the result shows that all these efforts have been to good effect.

BRITISH COLUMBIA

Alfred J. T. Taylor, who was head of the Taylor Engineering Company, Vancouver, which constructed the railway from Alice Arm to the Dolly Warden Mine and which afterwards took over the management of the mine, is moving to Toronto Ont., where he has been appointed vice-president and managing director of the Combustion Engineering Corporation, Ltd.

Discovery at Sandon.— The Reco Mine, Sandon Camp, is the scene of a new discovery, a fifth lead having been uncovered, three feet in width and carrying good values. Important development also is being carried on upon No. 2 Vein and the prospects are that the property will continue to be an important producer. The Reco Mine's four developed veins have yielded some $1,250,000 in the past, taking smelter returns as the basis for an estimate.

Discussion on Mine Taxation.— At a meeting of the Mining Association of the interior of British Columbia, held recently at Nelson, the interpretation of the clause of the Provincial Taxation Act, providing that allowances shall be made for depletion and depreciation, was discussed. The government has agreed that such allowance shall be made but the regulations for applying the same have not been issued. T. W. Bingay, J. P. McFadden, and C. B. White were appointed a committee to report on the regulations in question when they are issued. The Association went on record as opposed to the "Electrical Energy Inspection Bill" now before the provincial legislature. It was argued that this measure would be likely to come into conflict with Dominion regulations "for the control and distribution of electrical energy and modes of inspection thereof"; that it was not desirable that a "Dominion bureau of standards should be capable of being annulled by a Provincial Statute"; and that the effect would be to add to the "unnecessary and damaging overload of indirect taxation on the mining and other industries"; and that the proposal to limit the right of appeal to the Minister of Public Works was "dangerous and subversive of justice." Officers were elected as follows: President, R. Randolph Bruce, Invermere; J. P. McFadden, vice president; W. H. Burgess, secretary-treasurer; directors, S. S. Fowler, James Anderson, W. A. Cameron, T. W. Bingay, S. G. Blaylock, W. T. McDowell and three others yet to be named.

Trail Ore Receipts.— Ore receipts at the Trail smelter of the Consolidated Mining & Smelting Co. for the week from December 1 to 7 totalled 5,672 tons. Of this 5,039 tons were contributed by the company's mines. The other lots were made up as follows: Alamo, Alamo, 43 tons; Bell, Beaverdell, 43; Black Rock, Northport, 45; Knob Hill, Republic, 97; Paradise, Lake Windermere, 38; G. Peterson, Ainsworth, 23; Guilp, Republic, 103; Silversmith, Sandon, 79; Surprise, Republic, 162.

Consolidated to Resume Dividends.— J. J. Warren, president of the Consolidated Mining & Smelting Co., is quoted unofficially stating that the company will resume the payment of dividends at the end of the year. The last payment was in 1920, when the total disbursement was brought to $6,836,877, the distribution at that time amounting to $790,026. The annual report, it is stated, will say that the shareholders will have no reason to complain of the year's business. Ore receipts are shown to have been between 7,000 and 8,000 tons weekly and prices of metal in Canada and elsewhere on the whole have been favorable. The completion of the concentrator at Kimberley will lower costs, as the transportation of ore from the Sullivan Mine to the smelter will be materially lowered. The metallurgical plant of the smelter will be able to extend its custom business, while provision for an adequate volume of hydro-electric power and other improvement have put the company in a strong position.

Portland Canal.— The Mobile Mines Ltd., with a capitalization of $700,000, is opening up a property known as the Mobile Group, situated on the south fork of Glacier Creek at an elevation of about 1,000 feet above the old Portland Canal Mine workings. The ore carries high values in silver. Winter accommodation has been provided for a small crew and some shipments will be made by raw hiding to the Bear river wagon road, thence by sleigh to tidewater.

Exploration of Iron Ore Deposits.— Legislation is under consideration by the British Columbia Legislature having as its object the ratification of an agreement entered into between the Provincial and the Dominion Departments of Mines with reference to the exploration of the iron ore deposits of British Columbia. The Canadian Geological Survey, Ottawa, is to carry out the geological and topografical work and the Province it is proposed, will supply the funds to permit trenching, the sinking of pits, and drilling necessary to obtain information upon which to base an estimate of the tonnage of iron ore available for commercial use. The measure refers to give the Minister of Mines power to expend up to $50,000 on this work during 1923. Dr. G. A. Young, of the Survey, made a preliminary reconnaissance last summer. He will continue next year and will supervise any exploratory work that he may recommend as being needed to assist him in arriving at a quantitative estimate of the important iron ore deposits.

In introducing this Bill, Hon. Wm. Sloan, Minister of Mines, said:

"The agreement is the result of conference between the Geological Survey Department of the Dominion Government and the Mines Department of our own Province.

"The bill gives the Minister of Mines the right to enter upon any mining property without the consent of the owner for the purpose of carrying on such trenching, drilling and other work as is advisable. The Dominion Government undertakes to advise the Province what to do in this regard and the responsibility is on the Dominion to advise regarding the artificial exposure of ore, and the Dominion will make all necessary assays and other laboratory investigation of ore disposed. The Geological Survey will bear the cost of this work. The Province undertakes to do the actual exposing of the ore.

"Section 2 gives the minister the power to charge against the properties affected such portion of the cost of the work as he deems advisable.

"I have kept this section before the House to see what representations would be made as this is a large power to invest with the minister. The only representations that have come had been highly favorable as the iron ore resources of the province have hitherto been held for speculative purpose largely and very little work has been done. It is apparently agreed, therefore, that this power should be given the minister.

"The Dominion Government has appointed Dr. Young, its iron ore expert, in charge of the Dominion part of the work. He has done this kind of work with valuable results in New Brunswick, Ungava and northern Ontario, and comes well qualified and recommended for this work. He has already in the province and has spent four months this year examining iron deposits on the Coast. He is now in Ottawa preparing his report and will return to B. C., in January.

"The desirability of co-operation between the Province and the Dominion in the matter of a thorough exploration of the Iron Ore Deposits of British Columbia first was brought forcibly to my attention when some two years ago Major Crossland was appointed to investigate and report upon the tonnage of limonite ore in the Taseko district. The Canadian Geological Survey at the same time appointed Mr. Mackenzie to go into the same section for the purpose of making a topographical and geological survey. There was thus a certain amount of overlapping, and this agreement is designed to overcome any further such overlapping.

"In asking the Dominion to render assistance in this matter we have no hesitation, as under the terms of Union the Dominion Government agreed to undertake the expense of a geological survey in British Columbia. I have often in this House urged the necessity of that work being prosecuted vigorously in the interests of British Columbia mining.

"The Dominion Government did a great deal to build up the iron and steel industry in Nova Scotia. Under the Laurier government between $14,000,000 and $15,000,000 was spent to build up that industry by bounties. This province was not then in a position to avail itself of that policy, but I wish to draw attention to the fact that the people of this province contribued a large portion toward those bounties which were paid out in Nova Scotia.

"This Department has always taken the attitude that there were sufficient exposures of ore in B. C., to warrant the starting of a modest industry. The work done under this agreement will help to extend our knowledge of the iron deposits and will help to bring the facts before the public as to desirability of establishing an industry. There is every necessity that the work be proceeded with at once and for the purposes of the first year we are asking a vote of $50,000, which will be largely charged to the properties benefitted.

"Nothing will stimulate industary in British Columbia so much as the establishment of an iron and steel indnstry, which has been justly said to be the basis of all industrial enterprise. The Dominion has assisted in building up a great industry in eastern Canada. It started in a small way with a little forge employing 10 men. By means of the bounties these operations were extended, the Nova Scotia Steel Company and the Dominion Iron and Steel Company taking advantage of the bounties. These have now amalgamated as the British Empire Steel Corporation, one of the largest steel companies in the world. From that little beginning these companies have now blocked out on Bell Island a huge reserve of ore running 48 to 52 per cent. metallic iron in one of the largest ore deposits in the world, twice as large as the holdings of the United States Steel Corporation. This shows what can be done with proper government assistance.

"It is only a little over half a century ago that eight coal miners landed on Vancouver Island to open up the coal mine of Vancouver Island. Working first at Port Rupert they sent a small shipment to San Francisco, but this proved disappointing and they moved to Nanaimo. From that small beginning has come the great coal industry of British Columbia, which is not only valuable for the tonnage produced, but for the knowledge that it has given us of the coal resources in British Columbia, not only on Vancouver Island, but in the Nicola and in the Rockies".

The Minister traced also the great development in metalliferous mining, referring to Kimberly, Stewart and Atlin, where some of the greatest properties in the world were being developed from small beginnings.

"British Columbia is an Empire in extent", he continued. "The instances I have cited show the marvellous development of the past few years. An iron and steel industry will not only promote other industry, but trade and commerce and navigation which are matters of Dominion interest, and the Dominion cannot object if we ask them for material assistance in developing this industry in British Columbia.

"It requires no vision to agree with the prophecy made a few years ago by a distinguished statesman that the chief theatre of development and activity for the coming century will be on the shores and island of the Pacific, and in that development British Columbia with its hundreds of miles of coast line studded with fine harbors will have a great part.

"I believe that this agreement which I am asking the Legislature to ratify will have much to do with the development of the province in the next few years".

Strike Abandoned.— A strike has been called in District No. 18, United Mine Workers of America. Thus far it seems to have affected only certain coal fields in the Province of Alberta. The Crow's Nest Pass and other parts of eastern British Columbia have not yet been drawn into the trouble. Headquarters of the U. M. W. of A., Calgary, Alberta explained at the outset that the Union was demanding recognition and an agreement to negotiate a wage scale in the local field. Subsequently intimation was received that the strike was not authorized by the U. M. W. of A., that the men had not really gone on strike but merely had ceased work in order to hold a meeting to discuss certain grievances, and that the entire situation was to be investigated by the Union. Meanwhile on December 4th, intimation was received of the arrest of William Ryan, Vice-President of the U. M. W. of A. at the Black Diamond Mine near Edmonton, on a charge of having refused to the Company's premises when ordered to do so. Conditions and the issues seem rather confused. There is no doubt, however, that most of the mines are working without interruption and production is not likely to be seriously affected by these disturbances.

Settlers Claim Coal Rights.— The question of the claims of certain pioneer settlers within the Esquimalt and Nanaimo Railway Land Belt, Vancouver Island, to the under surface rights of land upon which they settled, was before the Provincial Legislature a few days ago. Hon. Wm. Sloan, Minister of Mines, reviewed the history of the efforts that have been made to secure the coal underlying these lands for the settlers able to prove their right to the same. He explained that the Van-

couver Island Settlers' Rights Act had been enacted by the British Columbia Legislature several times, but had not been allowed to become law by the Lieutenant Governor. For this reason before the measure was again enacted, British Columbia had asked the Dominion whether there was any likelihood of a change in its attitude. Replies received from the present federal premier indicated that no charge is likely and for that reason it was considered useless to again introduce and pass the measure.

Coal Mine Accident.—Alfred Odgers, a fireboss, and Gilbert McBroom, a pumpman in the employ of the Western Fuel Corporation of Canada, were killed by an explosion which took place on November 24th last, in the Wakesiah Mine, near Nanaimo. The jury brought in a verdict of death from an explosion of gas, attaching no blame to anyone.

In the course of the Coroner's inquiry, evidence of rather more than usual interest was adduced. W. H. Moore, manager of the mine said:

"There is no doubt in my mind that gas was ignited by the safety lamp which Odgers was using. The lamp was sitting within twenty one feet of the nozzle of the hose through which Odgers had blown compressed air in order to clear the place of gas which he had found there. He blew the gas through the gauze of the lamp. There is no doubt that every make of safety lamp will pass flame at a certain temperature.

"So far as velocity is concerned, it is not unusual on the compressed air line, to have a pressure of from 2000 to 3000 feet per minute. In this case I think an explosive mixture was driven through the lamp and that the initial point of ignition came from the lamp. A hot lamp is not safe at a velocity of 3600 feet per minute. I believe there have been scores of cases where explosions have been attributed to some fantastic reason, when the real reason was a safety lamp. But never before has an explosion been so clearly demonstrated as having come from a safety lamp."

Sam Mottishaw, who had had a seventeen years' experience as a fireboss, was firmly of the opinion that the explosion was caused by the gas being driven through the safety lamp. After the explosion, Mr. Mottishaw stated he was in the lamp cabin when the lamp was brought in and tested. He saw four explosions take place in the lamp. He then explained how it would be possible for a safety to ignite gas. In the gauze there were 784 perforations to the square inch, when the gauze is cold or normal condition, the flame will not pass through these openings, but if the gauze becomes heated the flames will jet through. He believed the velocity, even without the lamp's being heated, would cause the explosion, or soot on the gauze would cause the gas to ignite.

Estimated Coal Production for 1922.—The coal output of British Columbia for 1922 will be approximately 2,620,669 tons, according to monthly figures from the collieries. This allows 250,000 tons for the month of December. As the production for the month of September was 267,355 tons, for October 251,631 and for November 350,032, it seems safe to place that for the last month of the year at around a quarter of a million tons. Note, however, should be taken of the fact that the Canadian Collieries (D) Ltd. have found it necessary to close down one of their Cumberland mines. Still, although the effect of this may be felt, the loss should be absorbed without material reduction in the grand total. Official returns for the year 1921 placed production at 2,483,995 tons, so that December has to account for some 113,326 tons to equal the figure of the previous year. This will be done without trouble. The chances are that it will be substantially exceeded, but it also is probable that when final official statistics are out for 1922 it will be found that there is not much difference between the two years.

Quick Recovery of Crow's Nest Production.—One of the features of the year in British Columbia coal Mining has been the recovery of the Crow's Nest Pass field after the strike trouble of the opening months of 1922. For a considerable time the mines of Coal Creek and of other parts of the district were idle. When the differences were adjusted the mines almost immediately jumped in point of production to their usual monthly average tonnage. They have remained steadily at that figure throughout the remainder of the year. This is an achievement, when it is remembered that it is no easy task to quickly place a coal mine that has been inactive for a long period in a healthy condition as to output and also that, of late, the collieries of the eastern part of the province have been handicapped by the effects of the Fordney Tariff. The imposition of 53 cents a ton on soft coal entering the United States applies to all Canadian coal, it is true, but in the Crow's Nest it hurts, perhaps, more that it does on the Coast for the reason that the Great Northern Ry. Co. takes a considerable quantity of the coal produced there. Coke, of course, still is manufactured for the Trail smelter, but the market for that fuel has been curtailed in recent years by the closing down of the boundary smelters. W. R. Wilson, president of the Crow's Nest Pass Coal Co., now is turning his attention to the prairie trade and having a better quality coal that most of that of the Province of Alberta, it should be possible, given anything like a chance in the matter of freight charges, to popularize the fuel of the Crow's Nest for domestic use in the provinces of Saskatchewan and Manitoba.

Coalmont Coal Company.—In the Nicola Princeton Field there has been one development of outstanding importance, namely, the development of the Coalmont Coal Company. The coal of this mine is of good grade. Production has been brought up to around 700 or 800 tons a day. Of this the Great Northern Ry. Co. is reported to be absorbing some 500 tons a day. The Company has materially extended and improved its equipment and its underground workings are rapidly growing. The Princeton and Middlesboro Collieries are maintaining a steady output. The Kettle Valley Ry. uses a considerable quantity of the [illegible] latter Company. As yet the output [illegible] been able to loosen in market [illegible] Vancouver Island coal has on the [illegible] market of the Coast.

Vancouver Island Production.—On Vancouver Island the production has fluctuated during the year as the demand stiffened or slackened. There have been months when the large operators [illegible] worked only part time. At [illegible] United States strike had been [illegible] its effects felt [illegible] Western Fuel Corporation of Canada [illegible] full capacity and its output for [illegible] new record. Then the Cumberland Collieries [illegible] the mines of other companies [illegible] could be taken care of and that [illegible] withstanding that the domestic [illegible] activity but not to an [illegible] coal export trade is not [illegible] conclusively prove that [illegible]

Collieries in ceasing work in one of their Cumberland Mines. Considered comparatively, however, the year cannot be termed unsatisfactory from the viewpoint of island collieries. There have been no labour troubles, the feeling between employee and employer was never better. The Canadian Collieries and the Western Fue. Co. both have been prospecting and exploring new ground. A new mine is to be opened up by an independent operator near Nanaimo and shortly is expected to be on a producing basis.

OIL PRODUCTION IN SOVIET RUSSIA

The following report, originating in a Morocow paper and quoted in U. S. Commerce Reports, will give some idea of present conditions in the Baku oilfields near the Black Sea. The pood is 36 pounds.

The financial situation in the Azneft is as follows: Between January 1 and September 1 we have shipped into the interior 120,000,000 poods of petroleum products, to the value of 61,000,000 gold rubles, and against it we have received from the central govt. only 3,500,000 to 4,000,000 rubles, so that we had to shift for ourselves to cover our operating expenses, mainly by selling our products abroad and into Transcaucasia. But this can not go on.

At present we are managing our foreign business through the Arcos, but its organization is not strong enough and is unable to take care of our large stocks of kerosene and oils stored at Batum, while no other organizations are permit ted to sell kerosene abroad.

Under the program of production for 1922-23 of 240,-000,000 poods, we would have to start drilling 192 new wells, aggregating in depth 80,000 to 90,000 yards for the year, which would cost 25,000,000 gold rubles, 40 per cent of which sum must be furnished at once in soviet currency and the rest in installments. Under the smaller program, for a production of 205,000,000 poods, the cost of drilling new wells will amount to 17,000,000 to 18,000,000 gold rubles.

It must also be borne in mind that by November 1 our supplies of petroleum products at Baku will be completely exhausted and that at the opening of the next navigation season the supplies will not exceed 50,000,000 poods of products, and of a questionable quality at that, out of residues. Consequently, without forcing new drilling, an oil famine in 1923 is unavoidable, and therefore money for drilling is needed at once. As to operating funds, the sum required is 96,000,000 gold rubles for the larger program and 82,000,000 for the smaller one.

The New Modder, described as "the Rand's richest gold mine," has reduced its working costs from 22s to 10d per ton, as of 1921, to 16s. 9.6d during the financial year just closed.

Advertisements other than "Employment Wanted" or "Employees Wanted" will be inserted in this department at the rate of 20 cents per agate line (14 agate lines make one inch) $2.80 per inch, each insertion, payable in advance. Space measured from rule to rule. When four or more consecutive insertions of the same advertisement are ordered a discount of 25 per cent. will be allowed.

Advertisements of "Wanted Employment" or "Wanted Employees" will be inserted at the rate of two cents a word, net. Cash must accompany order. If box number is used, enclose ten cents extra for postage in forwarding replies. Minimum charge 50 cents.

FOR SALE: — Felspar property situated in Eastern Ontario adjacent to the I. B. N. O. Railway about one mile from public siding. Government assay shows good commercial spar. Willing to form small company to operate this property. Apply J. Grigor, 420 Manning Ave., Toronto.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eigth page, every issue, three headings; one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings; full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machine ry or supplies as they desire are invitedto write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.

A HAPPY NEW YEAR

Gold mining withstands the difficulties of every climate and unfavorable geographical situation. While the production of iron and the winning of coal can only be carried on successfully on a large scale, they are [also] dependent on trade conditions. —W. G. Miller — 1902.

SOME CANADIAN MINES

This is the stock-taking time of year. During the next few weeks the mining industry of Canada will be examined from every angle, weighed, judged, criticised, commended. Some of this discussion will be interesting, and much of it will be useful. We wish to prepare for it today by setting down a small item of information that may serve as a basis for comparison during the ensuing weeks when a sense of proportion is more than likely to give way to special pleading or sectional enthusiasm.

The great mining camps of the world are, quite properly, known by their names; their records of production are seldom appended. Yet this record is the truly significant feature. It will be pertinent to glance at the records of some Canadian camps and their prospects for the future.

The asbestos industry of Quebec has produced $100,000,000. Its reserves contain an equal or greater value, and no end of the deposits is yet in sight. The world can look to Quebec for its supply of high-grade asbestos for many, many years to come.

Similarly, the Sudbury nickel field, with a production of close on $200,000,000, has reserves that can at least duplicate the record to date and much of the productive area still unexplored can be depended upon to preserve for decades its present virtual monopoly, which is dependent solely upon the richness of the ore.

The Cobalt silver mines have produced more than $200,000,000 in silver. The camp is past its zenith, but will add scores of millions yet to its record. The adjoining South Lorrain mines are waxing as the older mines wane.

The Porcupine gold camp, still in the first flush of youth, gives promise of being the largest producer of mineral wealth in Canada. With $100,000,000 to its credit already, ore reserves that promise as much in addition, and several times the total visible to be expected rationally, it will be hard to beat.

The Rossland gold-copper camp, with all its richer ore extracted, is still going strong on ore of lower grade. Its record of $80,000,000 from such a small area is remarkable.

The Phoenix has failed to renew its youth, the mines are exhausted. But before the pumps were pulled, the satisfactory total of $65,000,000 had been taken from these famous old mines.

On the Coast, the mines are still youthful, with records still in the making. The Britannia mine, which with new equipment will soon be the largest producer of copper in the Empire, has already a record of $25,000,000, just as a good "starter."

These are a few of the camps with established records. Many, such as Sullivan, Mayo, Hidden Creek and Kirkland, are merely commencing careers of usefulness.

While the records of these Canadian camps cannot compare with such a unique producer as the Rand, they do compare very favourably with the majority of the world's famous mining camps.

THE PROFESSIONAL PROSPECTOR'S

On numerous occasions we have referred in these columns to the fact that the typical Canadian prospector of today is a very different person from his predecessor of even two decades ago. While this fact and its significance have been grasped clearly by those whose lot it is to move among prospectors and to deal with them, there remains a large part, perhaps a majority, of those in the mining industry who do not, or will not, notice the change.

This failure on the part of many to realize the present status of the prospector and his work in Canada has a noticeably detrimental effect on the mining industry. There was distinct evidence of this at the annual meeting of the Canadian Institute of Mining and Metallurgy in Ottawa last March. When prospectors were mentioned by a number of the speakers it was obvious that they looked upon these pioneers as distinct and separate from those of the mining profession, and relegated them to a very lowly position indeed among those attendant on the mining industry.

The popular misconceptions about the prospector do not help the case at all. He is commonly regarded as a misguided enthusiast who is hunting for a needle in a haystack. Sometimes he has the luck to happen on the needle, and that keeps the supply of new mines up to requirement.

The facts about the present day prospector are, of course, quite otherwise. He is a far [illegible] than

usual intelligence and perspicuity, and is possessed not only of the inward urge that impels all pioneers, but must have in more than ordinary degree the perspicacity that is characteristic of the Anglo-Saxon race. To keep at his chosen work faithfully, day after day, month after month and season after season, often in the face of successive and bitter disappointments, is a test of character that few of his fellow-beings are called upon to face. The modern prospector's life may not have all the glamour that is sometimes ascribed to it; but it has enough action and excitement to hold the interest of a well-selected lot of vigorous Canadians, the true story of whose accomplishment and sheer courage would cause many of the rest of us to feel ashamed of our efforts, puny in comparison.

Today we print an account of prospecting, written by a prospector. Mr. Tom Saville is known to a wide circle in the mining community of Ontario. His story almost tempts us to desert the editorial chair for a season. But Mr. Saville uses his story for a purpose. He does here what many a prospector has done round the camp-fire; he provides an idea for his friend the geologist to work on. Many a fine-spun geological theory is woven from material provided by the acute observations of the prospector. Usually (but not always) the geologist has acknowledged the source of his inspiration.

Most valuable in Mr. Saville's article, though, is the direct and indubitable evidence of the progress of the prospector along the road of learning. His acquirements in the way of technical information are now of considerable proportions, and he is advancing with almost unbelievable rapidity. Two decades of time have witnessed progress that few would have predicted. The effect on our mineral industry is bound to be of first-rate importance; indeed, we are already reaping the benefit of the trained prospector's well-directed efforts. The time may come when even the Canadian Institute of Mining and Metallurgy will recognize the prospector as the equal of those among its members that are willing, and indeed anxious, to follow the trail that he blazes.

WHERE DO THE METALS GO?

One sometimes wonders what happens to the world's ever-increasing output of metals and non-metallic minerals,—an output that we are told will continue to grow indefinitely. It is hardly likely that the present rate of increase in the annual consumption of mineral products will last indefinitely; but we are not yet in sight of the time when even the per capita consumption will remain stationary. As was aptly said recently by a prominent Canadian metallurgist, mining is the basic industry of progress, as agriculture is of subsistence. Consequently, as long as our material civilization continues to progress and with it our demands for further creature comfort, so long will mineral production proceed apace.

Sometimes we think of the world's metal as a cumulative quantity to which is added an annual quota of huge dimensions. This is partly the case, and particularly so in Canada, where our population is expanding so rapidly and with it the requirements in metal that are necessities in this age and in this country. Every settler must have his stove, agricultural implements and tools of iron and steel, to say nothing of nails, hinges and a hundred such incidental requirements. Wire fencing will amount eventually to many hundred-weights, or even tons, on his farm. To market his products he must have a wagon or an automobile and sleighs, as well as a railway within a reasonable distance, all these transportation facilities being large consumers of iron and steel as well as of the other metals. As settlement progresses, the proportion of metals used increases rapidly. Telephone and electric transmission lines, a wide range of labour-saving machinery and modernly equipped farm buildings swell considerably the amount of metals per capita. Similarly with non-metallic products, the farmer is a large consumer. The growing use of cement and drain tiles will serve to illustrate the tendency.

In the towns and cities, there is an even greater dependence upon mineral products, though as much by way of convenience and luxury as of necessity. The weight of the iron and steel pipe necessary to serve a single house with water and to distribute the heat from its furnace will surprise most householders. There are yards of drain pipe for each dwelling. The barrels of cement required for the foundations, sidewalks and pavement required for each house have done their bit in helping to absorb the millions of dollars of "water" from the stock of our famous (or notorious) cement merger. The bricks that are in growing favour for houses are a mineral product, as is the lime in the mortar. As for dishes—the mineral industry should, in mere justice, raise a memorial to the dish-smasher,—not that we can ever forget her or be without her.

This list could be extended to include steamships, all our electric facilities, and a host of the mechanical features of our civilization. But we shall desist, merely adding a mention of the means whereby the metals are returned again to mother earth, mainly as the oxides from which they were derived originally. This mention of oxides gives the key to most of the wastage. Only a small proportion of the rolled sheet products of iron and steel are ever recovered as scrap, and this probably aids to a measurable extent in maintaining the tremendous dimensions of the world's annual output of iron and steel. The salvage of copper, less subject to oxidation, reaches significant proportions. Aluminium also can be reclaimed in large degree. As for non-metallic minerals, it is seldom that they can serve any but their original use.

All things considered, there is no danger of this or the next generation of mining engineers being out of a job on account of a slacking off in the demand for mineral products.

HUMAN EFFICIENCY

A very interesting and instructive presidential address was delievered last month by Professor E. P. Catheart to the Physiology Section of the British Association.

The address to which we are referring was entitled "The Efficiency of Man and the Factors which Influence It"; and the speaker gave it as his opinion that there were at least four factors which played predominant parts in the attainment of maximum efficiency. These four factors he pronounced to be the following: First, the rate of the performance of work; secondly, the amount of rest offered to, or taken by, the subject; thirdly, the rhythm with which the work is performed; and, fourthly, the work habits developed by the worker. These factors are all intimately related, and, in fact, usually merge into one another.

Of the four factors mentioned, it is certain that most attention is usually devoted to the rate of speed at which the work is carried out. Indeed, it is probable that, in this connection, the old adage, "Time is money," has, like a good many other half-truths, been overworked and has been responsible for much false philosophy. In Professor Catheart's opinion, at any rate, the correct stress on the relation of speed to general industrial efficiency is that which is thus laid: "No movement can be compared with another and said to be better than it merely on account of its speed; it should only be compared in respect to ease and final result." If this is right—and we are disposed to think it is—then those who believe that maximum efficieney can be best obtained by mere speeding-up are thinking along wrong lines.

One of the chief sources of general inefficiency among workers is a wrong diet. The inadequately or wrongly fed worker is incapable of the best work. Then the worker is affected by the monotony or fatigue of his work. There is, possibly, a close relationship between monotony and fatigue, but the two are not identical. As regards the former, the temperament of the individual worker plays an enormous part in determining whether a particular operation in a plant is a monotonous one. So far as fatigue is concerned, this is often closely related to several other factors, such as the lighting, heat and ventilation of the plant. For example, in very many plants it will be found that the late afternoon is the most unproductive period of the entire day, and fatigue is the chief reason for this unprodnctivity, with lack of pure, fresh air as the primary cause of the fatigue. With this question of fatigue, too, the mode of life led by the worker outside his definite hours of labor, his housing and so forth have a good deal to do.

In short, individual industrial efficiency cannot be casually referred to any single factor, for it is dependent upon a multiplicity of factors, most of them, doubtless, more or less correlated. It cannot be said of real industrial efficiency that it means just the mere capacity of the individual to perform so many kilogrammetres of work in a given time with the smallest expenditure of energy. For all who have given thought to the matter realize that it means a good deal more than that. Indeed, as Professor Cathcart puts it, "the quest of efficieney is one of the most intricate problems, in its infinite ramifications of the physiological and sociological structure, which have ever called for solution, and it involves the whole welfare of our race and nation."

As such, it calls for the closest and most intimate cooperation between the scientific investigator, the employer and the employee. In such cooperation, it is obvious that work along the lines of welfare endeavor has an important role to play. The spirit of welfare work is that of goodwill, such as is only possible where employers and employees can get together in good comradeship. Negative goodwill, is of little worth in such a connection. The vital thing is active cooperation. In Canada, we have the plants, the skilled workers and the able direction. But still too largely the spirit of active cooperation is lacking. It can only be satisfactorily secured when mutual distrust of motives, capacities and methods is stilled. We need a larger statesmanship and a truer vision among all those concerned, in whatever capacity, with industrial relationships, not only in their wider national aspects, but in individual firms. And work along the lines of welfare endeavor affords an example as to the method by which not only class antagonisms, but even national antagonisms, may some day be allayed.

We note with interest the fact that in the current annual report of the mining engineer to the Temiskaming and Northern Ontario Railway the *Journal's* lead of a quotation from a Canadian mining man has been followed. The striking words of Dr. Barlow there quoted we used on April 14th last to inaugurate our series. His faith in the Northland is fast being fulfilled.

HYPAETHRAL LEGISLATION

(*"I smell a rat — I see it floating in the air." — Irish Parliamentary Speech.*)

Toronto Broker (loq.):—

A cloud, no larger than my hand, affronts
Th'untainted blue. No more promoters' stunts
Can be pulled off with that impunity
That marked the times of our immunity
From azure legislation. Henceforth we
Must act with care and with propriety
The little tricks we treasure in our trade,
The little turn by which our oof is made,
If one is caught at them 'twill be in vain the
Appeals for clemency from Mister Raney.

* * *

In other words, we guys are up the flue,
Upon my soul, I don't know what we'll do!
Twixt Mister Raney and that blasted Journal
We crack the nut and others get the kernel.
I see it coming rapidly, alas!
Standard Exchange — a Sunday Bible Class!

J. C. M.

The Future of Feldspar

by J. C. MURRAY

Very serious and concerted efforts are now being directed to the examination of conditions under which feldspar is quarried, shipped, and milled. The American Ceramic Society, a live and exceedingly active organization, through its official publication has collected and published much information bearing upon the possibility of adopting standard specifications whereby to regulate the quality of feldspar shipped. The question of formulating specifications is one beset with many difficulties and complications. To assist in defining these difficulties and in discovering correctives, the Society is to hold a special meeting in Pittsburgh in February next at which a large representation of both producers and consumers of feldspar is expected. It would be well-advised for all Canadians interested in feldspar to identify themselves with this movement by joining the Ceramic Society and attending the Pittsburgh meeting.

A few notes on the present status of the "specifications" problem will, perhaps, stimulate interest amongst those of the *Canadian Mining Journal's* readers who are concerned with feldspar.

In a discussion published in the Journal of the American Ceramic Society, November, 1922, Mr. Raymond B. Ladoo, of the United States Bureau of Mines, sums up matters thus:

"It is very necessary that both the feldspar producer and the consumer agree upon standards of feldspar for various uses, not only upon grades but upon types of feldspar and fineness of grinding. This subject must be approached, however, with great care, for opinions as to the needs of individual consumers differ. . . . . Specifications to be workable and satisfactory to both producers and consumers, must be formed by the joint action of men of wide experience, representing both producers and consumers . . . . . Absolute standardization of feldspar in the sense that is implied in the standardization of screw threads, of rail sizes and weights, etc, is impossible. Instead, an attempt should be made at first to draw up specifications for different uses giving rather wide tolerances. Such specifications might mention the most acceptable fineness for grinding, the total alkali content, the maximum allowable iron content, or whether or not impurities such as tourmaline, hornblende, garnet, pyrite, biotite, etc., shall be tolerated. It would be expected that these specifications would be revised at stated periods."

Another contributor to the discussion, Mr. W. H Landers, refers thus to the trouble caused by the presence of iron in feldspar: "So far, no one has been able to prevent dark specks completely in the fused samples when these are examined under a magnifying glass. There is no excuse, however, for these specks to be of such size as to be plainly visible to the naked eye. It represents bad milling practice or the improper choice of raw material." Mr. Landers proceeds to point out that, while millers may be very careful in their choice of raw material, far too much is taken for granted in the process of milling. "Plain engineering by some one not *too* familiar with the feldspar industry would greatly improve the quality of the product they turn out, especially as regards these iron specks."

Mr. Landers alludes pointedly to the danger of contamination with iron from sources other than the quarry. Mine cars, wagons, railway cars, cinders from locomotives, are all possible sources of contamination. "Tramp" iron may reach the feldspar from these and other points of contact. To a great extent these can be guarded against. One neglected precaution, however, is suggested by Mr. Landers. He scoffs at the possibility or serious contamination from jaw crushers, as the loss of iron from these crushers is "ridiculously low." But he suggests that it might be a good idea to get an analysis of some of the chaser stones now in use.

The outstanding feature of nearly all the recent discussions is the unqualified admission that the feldspar industry requires revision in a thorough-going manner.

The most radical changes in milling will, in all probability be recommended and gradually adopted. This will involve the scrapping of many old-fashioned plants that should have been condemned as obsolete long ago. The producer of feldspar will be forced to turn out a clean, graded product. Certain stated precautions and safeguards against contamination of the crude feldspar at the quarry, in transit, and in the mill will be adopted Competition will make it imperative that these precautions be observed. The producer or the miller who does not observe them will lose his business to the producer or miller who does observe them.

The movement for betterment of the industry is no flash in the pan. It is a serious movement sponsored by the United States Government and directed by capable business men. Canadians will lose a real opportunity if they do not follow the lead. It is to be regretted that the initiative was not not taken by our own Mines Branch The question was submitted to the Branch at Ottawa some time ago. The reception vouchsafed the request that the feldspar situation be looked into by officials of the Mines Branch affords a painful contrast to the zealous helpfulness of the United States Bureau of Mines.

A USEFUL DODGE

Some weeks ago, Mr. H. E. Holland, Mining Recorder of the Lake of the Woods District, having occasion to enlarge a map, bethought himself of the little toy radiopticon that his children amused themselves with. Inserting a plan of the region he wished to enlarge, he had no difficulty in so arranging it that it bore the necessary scale on the drawing paper. The outline was traced in pencil, afterwards inked in, and from this a copy on tracing cloth was finally made, permitting blue prints to be run off.

A draughtsman in the employ of the Backus Lumber company, on hearing of the recorder's success, hastened to invoke the aid of the radiopticon, and it is perhaps safe to say that no child's plaything was ever made to serve a more useful purpose.

To such engineers as happen to be places where there are no well-appointed draughting offices, the aid of some such modest instrument might be welcome.—C. A. B.

During 1921, Spain exported copper and its ores to the value of 7 million dollars; iron ore, three millions; iron pyrites, two millions; and pig lead 5 1-2 million dollars Quicksilver to the value of half a million dollars, and sphalerite, $100,000 were the only other mineral exports of note.

The Golden Mystery

THE MODERN PROSPECTOR CONTRIBUTES TO CURRENT ECONOMIC GEOLOGY.

BY TOM SAVILLE

A bunch of us savages had just got into the realm of the Iron Horse, fresh from the Grassy River country, and were eating up our mail at the Hudson's Bay Company's post at Fort Metagama. We were all feeling pretty good after bucking the ice for the last few days— it had caught us while camped on Ka-ste-pa-ka-ma, where we had run into some of Percy Hopkins' pet formation, the "Timiskaming Series," and had promptly forgotten that we were on our way out, running a race with the freeze-up, and that our grubstake was just about "all in." However, here we were, all of us, and everybody happy to be alive—and why shouldn't we be? This Hudson's Bay man was real glad to see us, and the door was thrown open wide.

Well, as I said before, we were all enjoying ourselves. Some good, green birch wood was burning in the open fire place. We were all dried out by this time and could hear moose meat frying for our supper. Pete was reading in the *Globe* about "the Terrible Turks." Bob, the American was lost in the *Literary Digest's* Prohibition Poll, and the Old Timer was scouting the last issue of the *Canadian Mining Journal* in the hope of locating some article that would throw light on "the golden mystery." Nobody was saying very much, but I could see that the Old Timer was priming himself to shoot something; for it don't take many moons camping and sleeping under the same Hudson Bays to get acquainted with your partner's little ways. The Old Timer never had very much to say, but when he did open his mouth to talk, he usually said something that made good listening.

"Say, boys, here's something that's real man's stuff and written in our language so as we can understand it." Reads Cyril Knight's latest report on Lightning River Gold Area. This, of course, starts something and all you can hear for a while is volcanics, shear zones, contacts, porphyry intrusions, and the Temiskaming Series. Then the Hudson's Bay man breaks in on us with a voice like Foghorn MacDonald's—"Here, you rock hounds! The moose meat's getting cold." "All right, boys," says the Old Timer. "Let's go feed and after supper when we get a smoke up I'll tell you something I've had on my mind for quite a while. It's a little story about the Iron Formation." So we pass in to the room to eat and are made acquainted with Mr. Hudson's Bay and family.

After McLeod, the factor, says "Magutch" we let him entertain us, while we entertain his moose meat. Then presently we hear him say, "Well, boys, times do change. I remember when you prospectors was a damn nuisance to the Hudson's Bay Company, and here we are all now with our moccasins under the same table."

"Yes," speaks up the Old Timer, "I mind making a trip down the Missinabi a few years ago hunting for them lost placers, and the Company would stake us to all the grub we needed to hunt and trap, but just enough to get to hell out of the country when they learnt we was prospectors. They claimed it would ruin the fur trade if the country got opened up."

"Well," says McLeod, "we have learnt that it is poor business to try and halt the march of progress, and the policy of the Company now is to help and share in the development of the country, and I sure do hope you boys dig up a mining camp back there where you were scouting this summer. How does she look, anyway?"

"Well," speaks up Bob, who up to this time had been a good listener, "she looks good enough to me to get an outfit and hunt and trap in there this winter so as to be ready for next spring. And I guess I won't have to travel very far to locate the rest of the bunch. I believe they are just as much in love with the possibilities of that country as I am."

"Did you see any gold?" says McLeod.

"Yes, we seen a little—nothing spectacular. But we don't worry much about that spectacular stuff now," says Bob.

"Well, what do you look for?" says McLeod. "Tell me something about this prospecting game. About all I know now is that if you fellows don't strike it this season, you come get an outfit about freeze up and hunt and trap until spring. That keeps the pot a boiling for the next summer's prospecting, I suppose. I'm living in this country with you fellows and I've interested in your work. Now, you'll be staying here for a few days until the ice takes, getting your outfits together, and if you care to tell me, I'd like to listen to an account of this prospecting game."

Bob sees that he is stuck for the talking, so he begins. "Us fellows that are in this game for keeps have learnt to take advantage of the other fellow's experience. This is the way it goes: the Department of Mines employs a bunch of Geologists that are crackerjacks at unravelling in a few of the summer months what it took Dame Nature some millions of years to wind up and hide. Their reports are written so that us fellows can follow them, and with them are maps showing the different rock formations. These are sent to us free for the asking and all that is necessary now when you are prospecting for gold is to read up these reports and look up the geology on the ground, and if there shows any Temiskaming Series with intrusions of porphyries kicking in, then we just sound round the contacts of the quartz porphyry, and on the porphyry itself if it should happen to be feldspar porphyry."

"That all sounds easy enough," says McLeod, "but how can you tell one rock from another?"

Well, I'll tell you," says Bob. "The Ontario Provincial Geologist, Dr. Miller, has written a book called Minerals and How They Occur. Where this comes in is there. Of course it is how you [illegible] but all the essentials are in that book, and it is how you build himself up pretty [illegible] to. And let me tell you that the prospector of today is taking advantage of most everything written that has to do with Economic Geology. Why, I'll bet the smallest kid of every one of this bunch of sourdoughs is packing around in his war bag some book on Geology."

"Well, well!" says McLeod. "I always thought you fellows despised that sort of high brow stuff."

"So we did till we learned we were cheating ourselves out of a lot of valuable information."

"Well, that's pretty good for a start," says McLeod, "and now that everybody's quit wrestling with the moose meat, what do you say we go throw on a couple of sticks of birch, and sit around and listen to old Bill and his story about his Iron Formation."

The Old Timer poked a dry sliver in the fire to light his pipe with, and then began. "The first time I run up agin' this Iron Formation was down in the Timagami, before the T. and N. O. was built, and you all know what that means—no Cobalt, or Kirkland Lake or Porcupine or any other mining camp in that neck of the woods. Dan O'Connor, the King of Timagami, was doing some work on a banded jaspilite-magnetite layout, and so was that grand old prospector Lanark, T. B. Caldwell. Major Leckie (bless him), the father of Jack, was scouting around a little to the north. C. C. Farr, the Father of Haileybury, was doing some scratching around Temiskaming, and that, with the Fergusons and the Wrights (Red and Marty) about completes the bunch of prospectors in the North at that time.

"Well, coming back to the Iron Formation, or Temiskaming Series (call it whatever you want to—it's all the same to old Bill), she's very much in evidence around Timagami, and I don't think that the story is all told yet about that district—not by a long shot! The next place I run into my friend the Iron Formation was in Cobalt. It's true there's not an awful lot exposed, but it's there, just the same. The next noise, as you will all remember, was up the Montreal River. I don't mind seeing any in Elk Lake—not till you get to Matachewan,—and you all know what transportation is going to do for that coming camp.

"When we work west from Elk Lake to Silver Lake, Bloom Lake, Calcite Lake, and into Gowganda, up crops our friend again. You don't need to be reminded that M. J. O'Brien has been working there on some of the richest silver veins in history.

"We continues our pilgrimage west again across Gowganda Lake, through Hangingstone, across the Wapoose, and as soon as we hit the iron formation at East Shining Tree, we likewise hit a likely-looking bunch of silver veins, and only that transportation is wrong, there might of been a different story to tell about it.

"When gold begins to get fashionable, we maunder west again along the belt hunting for the Iron Formation, and sure enough we run into it and some gold veins at Wasapika in the West Shining Tree country. Then we pay Porcupine a visit, just to compare notes, and we find the country up there's pretty much the same as the Grassy River country,—just lousy with Iron Formation. After Porcupine we jog along down to Kirkland Lake, and there she is again, occupying a front seat right along 'The Break.' And now Cyril Knight tells us (which same we was reading in the *Canadian Mining Journal*) that she's again doing business up in the Lightning River.

"Now, how can a fellow help getting suspicious about this Iron Formation? And, fellows, I got a hunch that some of the Big Four, (Miller, Knight, Burrows or Hopkins), will be solving the Golden Mystery by blaming it on the Prospector's Friend, THE IRON FORMATION."

The mineral resources of Northern Rhodesia are as yet not sufficiently developed to determine their importance. Most of the 290,000 square miles of this territory, north of the Zambezi river, is difficult of access, and a large part of the mineral-bearing zones is covered with detrital material. Nevertheless, the ores of copper, tin, lead, zinc and vanadium have been found in important amounts. It is considered by competent observers that Northern Rhodesia is one of the most promising mineral areas in the world for the skilled prospector.

LETTERS FROM READERS

The English Feldspar Trade

To the Editor, Canadian Mining Journal
Sir, —

I was interested in your editorial in the December 15th issue of the Journal on "Feldspar for Great Britain." As you said, Mr. Spence is "patently right" in basing his discouraging statements upon the costs of rail and ocean transportation as against the comparatively low price obtainable for crude feldspar in Great Britain.

The truth of the matter is that feldspar is not now used, nor has it been used for many years, as an ingredient of the body mixtures used in the manufacture of white earthenware, bone china etc., and, as the deposits of Cornish Stone in Great Britain are very extensive, there is little chance of feldspar from this side of the Atlantic replacing it. What feldspar is used in Great Britain is sold principally to the enamel ware trade, and the required amount of material is brought in to the pottery centres from Norway and Sweden in small sailing vessels of about 200 tons capacity. These boats can deliver their cargoes direct to the mills on the canals in the Staffordshire district. Practically all the English Cornish stone or feldspar is ground wet and sold to the potters with the water still in it, or, as it is called locally, "slop." In this way the costs of producing the material are reduced to a minimum, and even though Canadian 'spar were carefully graded and ground for the English market, the ultimate selling price in England would be so high that no potter would be able to purchase it. Also, freight rates increase as the value of the material increases, so that the cost of shipping the ground material would, in all probability, be nearly double that of crude feldspar.

The Editor is apparently not familiar with the ways of the English potter, or he would not suggest that it is quite possible that the use of Canadian 'spar might be a decided advantage. The U. S. Departement of Commerce Report No. 21 compares the pottery industries of the United States, England, Germany and Austria. On page 127 it is stated that in the earthernware potteries investigated in the United States feldspar formed 14.16 per cent of the body materials. In the English earthenware potteries investigated 20.15 per cent of China Stone was used in the body materials, and no feldspar. In 1912, the average cost of China stone delivered ground in six potteries investigated was $11.40 per gross ton. In the United States the average cost of feldspar was $11.33 per net ton.

In England the small boat freight charge has not increased in the same proportion as the rail freights in the United States, so that the Cornish stone would be further entrenched in the English market.

What feldspar is now being used in Staffordshire is being laid down at the mills for approximately $10.00 per ton, and Cornish stone for approximately the same price, *ground*. Therefore, there would not appear to be much chance of changing the practice of an industry such as the manufacture of pottery in England.

Ottawa, Ont. N. B. Davis

The larger part of the world's supply of antimony is derived from mines in China, where the ore reserves are sufficient for many years to come.

Mexico is still suffering from depression in her chief industry, mining. High taxation, labour difficulties, insecurity of titles and insufficient transportation facilities, along with the low-prevailing prices of some of the metals, have contributed to this result.

John David MacKenzie--an Appreciation

BY VICTOR DOLMAGE

When on the night of December 15th life passed out of the body of John David MacKenzie, the Geological Survey lost one of the most promissing geologists it has had, the mining industry of Canada lost a most useful and effective worker, and Canada lost a noble citizen. Just a week previous he had passed through Ottawa on the way from Vancouver to Montreal, and to all appearances was in excellent health and spirits. He had come east from Vancouver, where he was in charge of the British Columbia branch of the Geological Survey, to have an operation which he hoped would permanently cure an open wound, a result of the Great War. A preliminary operation was performed which showed that conditions were better than anticipated, and there was every hope that the final operation would be successful. After the effect of the anesthetic had passed he became conscious a few minutes. However, during the sleep that followed a blood clot lodged in the brain, which produced paralysis and then death.

MacKenzie was born in Baddeck, Cape Breton Island, in 1888, the eldest in a family of four. His two brothers lost their lives in the war. His father died when he was a lad, and he was, at an early age, left to work out his destiny with the help of his own wits and the guidance of an exceptionally capable mother. Just at this time he was fortunate in coming under the influence of Hugh Fletcher, the great Nova Scotian geologist, whose influence shaped his whole future career. Fletcher employed him as an assistant, encouraged him to continue his education, and materially assisted him in this direction. But he also did what was of far greater moment in MacKenzie's life,—he created in him a fervent ambition to be a great geologist, an ambition he dearly cherished all his life, which not only guided him into his profession but was a constant source of inspiration. At the age of sixteen he went to Boston and while supporting himself, studied in night school until he was able to fulfill the requirements of entrance into the Massachusetts Institute of Technology. He took the mining engineering course with the geological options, graduating in 1911. He spent the following winter at Cornell University in the position of instructor and graduate student. The following winter he returned to his Alma Mater to hold a similar position, and remained there till he completed the requirements for the degree of Doctor of Philosophy early in the Spring of 1916, when he joined the Nova Scotia Highlanders for service overseas.

Throughout the course of his education he spent all his summers in the employ of the Canadian Geological Survey, first as assistant to Fletcher in Nova Scotia, then as assistant to C. H. Clapp on Vancouver Island. In 1912 at the age of 24 he was given charge of work in the coal fields of the Eastern Rockies. 1913 and 1914 were spent in working out the difficult geology of Graham Island, the results of which work formed the basis for his doctor's thesis. The season of 1914 was one of the most strenuous of his pre-war days. The geology was difficult, outcrops were rare and it rained most of the time. Day after day he spent wading up the many small streams of the island in the pouring rain, surveying and doing the geology as he went. The same summer he narrowly escaped death by a gas explosion in an abandoned coal mine, and in August of the same year he and his party were shipwrecked on the Butterworth rocks about halfway between Graham Island and Prince Rupert and an anxious night was spent in the life boats. The season of 1915 was spent in the Telkwa district of north central British Columbia.

MacKenzie's efforts in the war, as in all his undertakings, were crowned with success. He attained the rank of acting Major and on August 10th, 1918, was awarded the Military Cross in recognition of his gallantry during operations east of Rosieres-en-Santerne. Three weeks later he was severely wounded, a piece of shrapnel passing through his left lung, causing the wound that finally resulted in his death. So serious was this wound that his recovery, even though slow and tedious, was regarded as almost miraculous. There is no doubt that it was partially accounted for by his wonderful spirit.

Shortly after his return to Canada he was transferred, much to his own satisfaction, to the military hospital in Esquimalt where his condition improved rapidly. Then followed the three happiest years of his life. While convalescing at Esquimalt he spent much of his time sailing his small sloop about the harbour. In the Spring of 1920 he rejoined the Survey and was put in charge of the British Columbia office. He was able to undertake and successfully complete a piece of field work on the limonite deposits of Taseko Lake district. During the same summer he married Mary Isabel Lord of New Westminster, who also served overseas with distinction as a nurse in the Canadian Army Medical Corps.

The summer of 1921 and 1922 were spent in doing a valuable piece of work on the Vancouver Island Coal fields. During these two years he made great strides towards the goal of his ambition. Owing to his long absence overseas and to the fact that he had never been but a temporary employee of the Survey, and had not even resided in Canada since he was a boy, he was almost a stranger when he took charge of the British Columbia office in succession to Mr. Camsell. Nevertheless, during the two and a half years that followed he not only completed two excellent pieces of field work with their attendant reports, but he published several other articles, gave many lectures, did a vast amount of work for the Canadian Institute of Mining and Metallurgy and gained a very high place in the respect and esteem of the mining public of British Columbia.

The following bibliography is a record of his work, and speaks for itself:—

1914 The Crowsnest volcanics, Canada, Dept. of Mines, Geol. Surv., Museum Bulletin no. 1, 37 pp., 1 pl., 1 fig. November 19, 1914.

South fork coal area, Oldman river, Alberta, Canada, Dept. of Mines, Geol. Surv., Summary Rept. 1971, pp. [illegible]16, 1 map, 1914.

Telkwa valley and vicinity, British Columbia, Canada, Dept. of Mines, Geol. Surv., Summary Rept. 1915, pp. [illegible] maps, 1916.

The Queen Charlotte Islands, Science, [illegible] no. 1, pp. 11-23, 8 figs. 1914.

1915 Flathead special map area, British Columbia, Canada, Dept. of Mines, Geol. Surv., Summary Rept. 1914, pp. [illegible] 1915.

The Historical and Structural Geology of the Southernmost Rocky Mountains in Canada. — Read before Royal Society of Canada, May 1922.

As a geologist MacKenzie's future seemed to be particularly bright. From the very first he showed promise. As a student he was endowed with an excellent memory and a quick perception, but always preferred history and literature to mathematics, and the natural to the exact sciences. His eight years of hard training at Boston Tech. and one year at Cornell University, together with his excellent field training under Fletcher and Clapp, gave him all that could be desired in the way of preparation for a life work. Added to this there was his great natural industry. He worked long hours and he worked at a high rate of speed. Only on rare occasions was he known to arrive at his office in Tech. later than eight o'clock. Even physically he was specially adapted to the work of a geologist. Standing well over 6 feet and of slight build, he was able to travel in the woods at a rate which few, even skilled woodsmen, could equal, and that he habitually did travel at that rate is well known to his assistants.

But probably his greatest asset as a geologist and that which more than anything else would have raised him into highest ranks of his profession was his devotion to the science, and that fervent ambition created in him by Fletcher, that dream of his boyhood which ever goaded him on to greater efforts. He not only read with avidity the works of all the great geologists, but had acquired a remarkably intimate knowledge of their biographies and of the history of the science. Hutton, Lyell, Huxley, Dana, Suess — these were his household gods.

As a man among men MacKenzie was unusually well liked. He had fine instincts, a wide range of knowledge outside his own science, with definitely formed opinions on many topics and an extraordinary sense of humour. There was much of the romantic in his nature, and a large share of sentiment. He was capable of feeling deep sympathies and forming warm affections, and had a patriotism so intense that it was to him at times almost a burden. His voluntary enlisment meant a great sacrifice. It meant the giving up of his dearest ambition just at a time when the chance of satisfying it began to seem possible; it meant throwing away the long, hard and valuable training that he had gained at such great cost and endeavour; and he had to leave many close friends. He gave up all these to take up a task he admittedly dreaded, because he believed it was his duty.

The last few days of his life were busy with finishing the various pieces of work he had on hand, and not the smallest detail seems to have been omitted. While on the train on his last trip east he wrote a short argument based on his own experiences proving that the actual passage from life to death is a painless process owing to an intermediate state of unconsciousness. The care with which he completed all his tasks and the impulse that caused him to write this discourse give us an inkling to some other thoughts that may have occupied his mind. As he sped eastward through the mountains he loved so well, and came out of the mountains into the foot-hills; as he crossed the great Lewis overthrust and came on to the Cretaceous rocks of the plains on which he did his first piece of independent geological work, and passed the structure of those rocks on which he had written almost his last scientific article, no doubt his keen and well-trained eye was once again occupied in reviewing those geological features; no doubt they again drank in a full share of their natural beauty; no doubt he loved those scenes that meant so much to him. It may be as he passed along that he thought he might not pass that way again. But he did not fear death.

Dr. Camsell has paid him this tribute:

> "John MacKenzie was one of the finest characters it has been my privilege to meet, — a character all too rare, and one that Canada or any other country can ill afford to lose. Irrespective of his high scientific training and attainments, which are undoubtedly a serious loss to our country, a far more serious loss is the leavening influence of such a character on the moral life of the nation.
>
> "It is easy to believe that the world is better for MacKenzie having lived, and the influence of his character will long remain with those with whom he was associated in the Geological Survey and the mining industry of Canada".

This tribute came from Dr. Collins, Director of the Survey:

> "MacKenzie was another of that small and mysterious band, touched with the seemingly tragic gift of genius, whom the gods love to take to themselves early. He was still young and had given generously to other needs of his country; nevertheless, he had already proven by his works as a geologist that he possessed that happy and uncommon combination of powerful imagination and capacity for exact and unstinted observation that is fundamental in all great scientists. In his death the Geological Survey has suffered an inestimable loss."

The following tributes come from two of the great teachers under whom he was developed from a raw recruit to a finished geologist, who knew best his liabilities and for whom he had a great affection. Reginald A. Daly sends this message.

> "MacKenzie was a practical idealist. His high quality early declared itself to us who knew him during the years of his training in geology. His professional success was due to an extraordinary will driving a fine intelligence. Fighting for his country through much of his mature life, MacKenzie could not fully show his scientific power so well known to his friends. Canadian and American geologists cannot but regret the heavy loss to their profession while doing homage to the man's nobility proved to the uttermost".

Waldemar Lindgren says:

> "From our geological section and from myself add this message. Our sorrow is deep that John D. Mackenzie has passed away. We knew him as a scholar of greatest ability, as the fellow instructor

Coal Dust in Winter

DURING COLD WEATHER INCOMING AIR CURRENTS MUST BE HUMIDIFIED TO AVOID DISASTER

By JOHN MOFFATT

It is generally admitted that coal dust explosions are more liable to occur in winter than in summer. The cause is well known and arises from the change in the mine atmosphere, due to the drying-out process continually going on when the temperature falls below the freezing point. The colder the weather and the harder the frost, the greater effect it has on the mine air, and within a few days a coal mine that had hitherto been comparatively safe with one hundred percent saturation of its atmosphere, becomes a place that requires immediate attention if a catastrophy is to be avoided.

During the summer months the temperature within the mine usually differs little from that outside—if anything it is lower and for that reason air entering by the intakes begins at once to give up its moisture, thus adding to the humidity of the mine. But when the frosty winter winds dry up the air that enters the warm mine, it begins to expand and to take up moisture, which it carries out of the mine, leaving it dry, dusty and dangerous. Robbed of its moisture, the quickly moving currents dry up the wet places, draw all dampness from the strata and from the coal, leaving no source of moisture from which they can become again saturated in their onward course to supply workmen with fresh air and relieve the mine of its foul breath.

Danger from Coal Dust

Coal dust, which is always floating in the mine to a greater or less extent, but which in a humid atmosphere becomes damp, rapidly accumulates under dry conditions and in these days of high-velocity air currents of great volume, the dust is distributed through the working parts of the mine. It collects on the floor, the walls and roof; on the tops and hidden parts of timber; on debris; on everything stationary, and becomes a standing menace to the safety of the mine. The change may take place slowly or it may take place in a week or less time and may generally have been unobserved. This makes the danger all the greater. Silently and stealthily the underground workings of a great colliery can be transformed from a safe condition to one of imminent danger. The explosion records of the past furnish ample evidence of this statement. The miner usually goes about his daily task, ignorant of what is going on around him. It may be that he notices that the dust in his section is lighter and drier and in greater quantity that before, but he attributes this to the greater depth of the mine and its advanced workings, or he may, in his matter of fact way, accept it as a natural condition to be expected, hence he is not alarmed over it.

But the observant Mine Manager has his eye bent on the change going on around him. He notes the pillars of cloud as the rapidly moving trip or the mine cars drawn by the pit horses pass on. He sees the bone-dry state of the mine and reads in it the signs of threatening disaster. He has his finger on the pulse of the mine and through the hygrometer readings day after day he can tell how near the mine is to the danger limit. All this time he has, no doubt, been getting ready to meet the change he saw coming and in a few days the walls of the mine are wet again, all coal dust becomes damp and danger is greatly lessened through the use of water sprays in the main airways.

The Ventilating Fan as Water Pump

The amount of moisture carried out of a coal mine in frosty weather is surprising. Records taken in some of the collieries in Nova Scotia range all the way from one-half gallon per 1000 cu. ft. of air to nine gallons. If the colliery is a large one with the volume of air passing at a velocity of 250,000 cu. ft. per minute, the amount of moisture carried out at the average temperature of the mine will be 160 tons per day. In one week no less than 1,120 tons of water will be carried out on the wings of the wind, and in the three frosty months of winter the mine will be relieved of 14,000 tons of water—much to its detriment.

The hygrometer for measuring the humidity of the mine atmosphere is a part of the equipment of all well regulated mines and daily readings are taken and recorded. Where conditions are found to be gradually becoming drier, other measures of safety are taken besides water sprays. In one of the largest collieries of Nova Scotia a wet zone has been formed. This is simply a district surrounded on the upper and lower sides by water. This water is held in the levels above and below this particular section of the mine. It is a comparatively easy thing to accomplish, as most of the lower levels of a coal mine, except at great depths, yield a considerable amount of water, and this can be trapped in the levels where it is required to be used.

Use of Hygrometer

In these days of free mining schools, technical training and the use of the latest devices in mine work, no one should be easily deceived as to mine conditions. If the roof and sides of the roadways are damp, it is sometimes taken for granted that this is the natural condition of the mine and that this moisture has all oozed out of the rock and the coal. No greater mistake can be made than to think along this line, without first having made personal investigation. A close examination at different seasons of the year is necessary to find out the natural condition of any coal mine. There is much evidence in a coal mine to cause a mine manager who is not observant and of studious habits to conclude that his mine is inclined to be wet, while the truth is just the opposite. A mine may, through its pumps, pour out ten, twelve, twenty or a

---

of infinite patience and skill, as a gentleman in the finest sense of the word, and as a trusted and true friend. He left us to take up arms for his country, and he died for it too. Had he lived he would have ranked with the highest in his science. We honour his memory."

hundred tons of water for each ton of coal produced, but that does not make it a wet colliery. The inner workings may be dry and the apparent "sweat" on its sides may be carried in by the mine atmosphere and left there. In the face of the hygrometer readings, skeptical managers may prefer to believe otherwise. But the practical, well-trained mine manager knows better and when the wet bulb readings give indication of low moisture in the mine air he is fully alive to his duties. Especially if his colliery is a gaseous one, he knows the increased danger of a large or even small percentage of coal dust in the atmosphere. Indeed, the mine manager of today has more dread of coal dust than of gas. The gas is diluted and carried out of the mine in the air currents, but coal dust collects everywhere and if not sent out of the mine in the pit box soon forms a combustible covering just as dangerous and far more deadly than the train of powder sometimes laid and used for ignition purposes in blasting.

Methods of Humidifying

Various methods of humidifying the air have been tried, but the one in common use today is that of water sprays. Steam was tried, but owing to the expense and its injurious effect on the mine roof and floors and on mine timber it was discarded, being found to be neither practical nor economical.

In installing the system of spraying one of the important things is to ascertain where the first spray jet will be placed in the intake airway. As air below freezing temperature carries little moisture, the thermometer will indicate the point where air expansion begins and where the air has been sufficiently warmed to take up moisture. Here a small water jet may be thrown into the air and this part of the airway being far enough away from the working districts to ensure absolute safety in case of an explosion, the effect of the small amount of moisture supplied will be sufficient for that particular section. The same principal is used as air becomes further heated, and spray jets are placed at points along the airway as their use may be indicated by temperature readings. In this way, perfect saturation or super-saturation of the mine atmosphere can be had, and the safety of the mine against dust explosions ensured.

The Richardson feldspar quarry, in the Verona district of Frontenac county, north of Kingson, Ontario, is shipping feldspar once more. A new spur railway and a good automobile road have recently been completed to provide cheap transportation from the property. It is being operated by Mr. R. F. Segsworth; 103 Bay Street, Toronto.

The United States Geological Survey's estimate of beehive coke production in 1921, made in March, was substantiated by final returns from the producers. These reports show that the total output was 5,538,042 net tons, the smallest record since 1885 and 73 per cent less than in 1920. By-product coke continued to supersede the beehive oven variety, and of the 25,287,22 tons of coke produced in 1921—both beehive and by-product—but 22 per cent of the total came from beehive ovens against 40 per cent in 1920.

CLAY PRODUCTS - 1921*

Of the 343 operators of clay deposits and producers of brick in Canada, only 199 carried on operations during 1921, the remainder being idle. The total value of the clay products made during that year amounted to $6,296,171 which was divided among the various provinces as follows: Nova Scotia $139,390; New Brunswick $26,300; Quebec $1,257,562; Ontario $3,800,858; Manitoba $208,982; Saskatchewan $166,244; Alberta $280,956, and British Columbia $415,869. The disposition of the known establishments and the value of production is shown in the following table. Ontario's production exceeds that of all other provinces combined by a considerable margin.

Province	Number of Establishments Active	Idle	Total	Value of Production
Nova Scotia	6	4	10	$ 139,390
New Brunswick	4	2	6	$ 26,300
Prince Edward Island	...	1	1	$ .....
Quebec	18	18	36	$1,257,562
Ontario	140	84	224	$3,800,858
Manitoba	5	10	15	$ 208,982
Saskatchewan	7	6	13	$ 166,244
Alberta	10	7	17	$ 280,966
British Columbia	10	11	21	$ 415,869
TOTAL FOR CANADA	199	144	343	$6,296,171

The principal producing countries of the maritime provinces were Pictou, Hants and King's in Nova Scotia, and in New Brunswick, York and Northumberland Counties, with smaller producers in Gloucester and Carleton. The individual values of production range from $4,000 to $43,000 per annum.

There are some large companies producing over $100,000 worth in Quebec, notably in La Prairie and Montmorency Counties. Other deposits in L'Islet, Sherbrooke Joliette, Quebec, Richmond and Champlain produced lesser amounts, ranging from about $4,000 to $30,000 worth per annum.

Ontario is by far the most important producing province in Canada. The extent of the industry may be approximately gauged in this province by selecting only those companies producing $10,000 worth or over and tabulating the values by counties.

Kent	$ 80,149	York	$1,685,298
Essex	102,941	Carleton	354,100
Lambton	74,521	Perth	
Middlesex	66,985	Peterboro	56,293
Grey		Prescott	
Waterloo	52,900	Frontenac	113,400
Oxford		Renfrew	75,483
Wentworth		Nipissing	
Lincoln	286,077	Algoma	84,175
Halton	478,379	Thunder Bay	
Peel	482,359		

In the western provinces, five Manitoba establishments averaged about $40,000 each; in Saskatchewan the average was about $24,000, Alberta about $30,000 and British Columbia in the neighborhood of $42,000. The total value of the production for the prairie provinces was $656,192 from 22 companies, and in British Columbia the value was $415,869 from 10 companies.

* Data provided by Dominion Bureau of Statistics

Recently an important part of the Roumanian oil fields passed into the control of the Phoenix Oil and Transport Company, a British corporation. It is predicted in some quarters that the new combined company will rival in importance the famous Shell group

A Budget From New York

BY KIRBY THOMAS

The Mining Revival in the Comstock and Goldfield District of Nevada

The Comstock district in Nevada was the scene of the first great mining boom in this country following "the days of old — the days of gold" in California. The first activities began in the '60's, and for nearly twenty-five years the district held the front rank in interests and in fabulous yield of the precious metals. In a few years the Comstock mines produced nearly a billion of dollars of gold and silver making many notable individual fortunes and profoundly affecting the development of the whole west. Then came the decline in the price of silver and the mines in depth yielded, at great cost, ores not amenable to the metallurgical processes of the day. Comstock sank into somnolence and to the present generation it became only a hectic, glorious memory. Several sporadic attempts to revive the operations in the district during recent years, were unsuccessful, partly because of insufficient capital, but chiefly because of the limited vision of their sponsors and the inadequacy of their program. Within the past two years new men and new interests have come into the Comstock story.

A financially strong group headed by Mr. Harry Payne Whitney of New York and technically directed by Mr. Bulkley Wells of Denver, acquired a large sector of the district and after extensive and expensive development, a mill of 2,000 tons daily capacity has been completed and has recently been put in operation, treating at a profit ores that were profitless to the earlier miners. The mine development, directed by skilled geologists, has disclosed large tonnages of new ore of very good grade. The activity and success of the undertaking in the old Comstock mines has led to a general revival of activities in the district and a new, large project has just been adequately financed to undertake even more extensive operations.

It is generally accepted now as a fact that the old Comstock district has come back and that it will again rank high among the sources of the country's needed supply of the precious metals.

In the same state a later comer among the great and sensational mining developments of the west — the Goldfield district — is also "coming back." This district was not discovered until 1902. In a little over ten years it yielded more than $100,000,000, mostly in gold, and paid more than $50,000,000 in dividends. Goldfield was a district of "bonanza" orebodies and the stories of the Aladdin results of the operators and lessors during the earlier years of the activities of mines of the Goldfield district are still too fresh in mind to require record. All too soon the rich orebodies were exhausted by the fevered and frantic efforts of the numerous companies formed to participate in this, the greatest gold boom of recent times. The companies improvidently failed to provide for exploration and development against the inevitable exhaustion of the "bonanzas", and the general financial stringency that overtook all development and speculative undertakings for nearly a decade past has made of Goldfield almost a deserted camp. However, there were those that had faith and vision and among them was Mr. George Wingfield, one of the beneficiaries of the boom days of the district who later became the responsible head of the district's greatest mine, the "Goldfield Consolidated Company". Mr. Wingfield and others associated with him, through several years untangled the affairs of the derelict companies and recently they have formed a company with strong financial backing to undertake a notable exploration program for the district. Operating as the "Goldfield Deep Mines Company" and owning more than 600 acres in the heart of the district, the company is actively sinking a great shaft to cut the main gold veins of the district at a depth of 2,400 feet. Most of the production from the district was from relatively shallow workings, none deeper than 1,400 feet. The new shaft will open the veins much below these workings and at a zone considered by the company's geologists and engineers to be favorable to the enrichment of the veins.

Several other companies in the Goldfield district have been stimulated to undertake developments on a larger scale, and it is likely that Goldfield will soon "come back", as has the earlier Comstock district.

WORLD'S LARGEST ROLLER-BEARING

The largest roller-bearing in the world is reported to be on exhibit at the Motor Show in London, England, before its shipment to Canada. It is four feet high, weighs more than a ton, and is of the chain type, like those recently tested by the British Railways. This giant bearing, and two others like it, will be installed in a Canadian pulp mill.

Large tube mills, with a capacity each of 600 tons in 24 hours, have been installed at the Spring Gold Mines, South Africa.

A new process for the production of magnesium metal by electrolysis at a low temperature has been worked out. A fused mixture of magnesium chloride with the chloride of sodium or potassium is electrolysed and the liberated magnesium alloyed with lead, in a bath beneath. This alloy is electrolysed, giving pure magnesium and renewing the lead for further use.

The principal use for fluorspar is as a flux in open hearth and electric furnaces, there being no satisfactory substitute for it for this purpose.

A recent survey of coal deposits in South Africa shows them to be of first rate importance. It is predicted, with good reason, that eventually they will prove of greater value to the country than the famous Rand gold mines.

There is a movement on foot in Britain to form a combination of iron and steel interests similar to the Steel Corporation of the United States.

An Iron and Steel Industry For British Columbia

OPTIMISTIC REPORT BY AN ENGLISH ENGINEER WHO HAS EXAMINED THE FIELD ON BEHALF OF THE BRITISH COLUMBIA GOVERNMENT

BY ROBERT DUNN

Below is a resumé of a report on the economic possibility of establishing an iron and steel industry in British Columbia at present. Mr. Williams, an English engineer, has spent the past season in gathering data, and his conclusion is most favourable to the immediate erection of a plant. His examinations have disclosed no new facts, so that his difference of conclusion from the engineers that have examined the case previously must rest upon his opinion. We should not care to accept the sweeping generalizations included in his report without a searching analysis of his data and of his deductions. Meantime, the report throws an interesting side-light on the problem. — Editor, C. M. J.

That an Iron and Steel Industry can be established in the Province:

That the necessary materials for the successful working of such an industry are available:

That there is a good and increasing market for the product:

That the time for the launching of such an industry is opportune at present:

That the enterprise should be most successful:

These are the conclusions reached by Mr. C. P. Williams, the English mining engineer, engaged by the Hon. William Sloan, Minister of Mines, to make a thorough investigation into the tonnage possibilities of the iron ore deposits of British Columbia and other iron ore bearing zones on the Pacific Coast as far south as Mexico and as far north as Alaska. The object was to endeavour to obtain such data that it might be clearly established either that full-sized iron and steel furnaces situated in this Province could or could not be maintained by material obtained on this Coast.

Mr. Williams' Training and Experience

The satisfactory nature of Mr. Williams' report from the standpoint of those desirous of seing such an industry launched is emphasized by the fact that Mr. Williams is one of the best qualified authorities that has yet investigated his question. After graduating from Victoria University, Manchester, he took a course in engineering with Messrs. Pearson and Knowles, of Warrington, one of the best known firms in Great Britain. Later he joined the designing staff of the Ebbw Yale Coal, Iron & Steel Co. when they were constructing their then new Bessemer plant and blast furnaces. From there he went to Germany, becoming an engineer with the Hoesch Co., Dortmund, one of the largest firms of coke and by-product producers and iron and steel manufacturers in that country. Coming back to England, he was engaged by the Brynbo Steel Company where under his direction extensions were undertaken that proved of immense benefit. During the war he occupied the post of Assistant General Manager to John Lysaght, Ltd., and under his management the company was the only British concern to successfully produce a bullet-proof alloy for armoured tanks. It will be recognized therefore that Mr. Williams both by technical training and by years of practical experience is well qualified to discuss the iron and steel problem in its relation to this Province.

"From my experience", Mr. Williams says, "in several European countries and from an inquiry into costs at a few eastern American works I am of the opinion that iron and steel can be manufactured on the Pacific Coast today as cheaply as in any of the well known iron and steel producing countries of the world, excepting Germany and possibly Belgium. The reason for their advantage is not that their costs of production *per se* are lower but that the present abnormal rate of exchange leaves the countries with a depreciated currency in a better position to export their finished articles than those countries whose rates of exchange have not fluctuated considerably from normal conditions.

"Again, there is every probability that an approximately proportional fluctuation in cost will take place in most of the world centres of the industry, with the result that as the conditions today in British Columbia compare favorably with conditions in other regions producing these goods, so will they compare equally favorably when costs of production elsewhere have decreased and conditions become more stable and normal all over the world."

Alternative Sites for Iron and Steel Plant

At this point Mr. Williams makes a statement of rather more than ordinary interest. He says that it is possible to outline for this Province not one iron and steel project only but several, each of which, in his opinion, eventually would become of very great importance. "All the conditions," he asserts, "are now present for establishing such an industry on a successful commercial basis. It is possible to sketch a plan for such a work at a suitable site on Vancouver Island and also one on the mainland near the coast." As between these two locations, however, a preference is expressed for a site on the Fraser River. On this point he says, "With respect to the location of the works and with due regard to the areas I have visited, my opinion is that the first iron and steel works of the Province should be on the Fraser River."

In supporting this contention Mr. Williams explains that there are economic factors involved such as the importing of certain material and commodities and the exporting of certain finished manufactured goods. The greatest market is on the mainland and he argues that to avoid heavy transportation costs and to reduce double handling to a minimum this site is to be recommended. All interior markets could be reached by rail and the position would be suitable for all coastwise and overseas export trade. Here suitable coking coals from the Nicola Valley, from the Comox district of Vancouver Island, or even, if it were necessry, from

the Crow's Nest coalfield could be assembled. Limestone could be brought in scows from the north end of Texada Island.

The Iron Ore Deposits

Discussing the iron ore deposits, the investigator states that there are suitable ores at different points in the eastern portion of British Columbia. He mentions the deposits of Kitchener, and Sand Creek near Fort Steele, that of Ironton opposite Proctor near Nelson, a large body near Rossland, one at Keremos, one at Bull River, and the International property near Waneta. In this region there are red and brown haematites, specular ore, and magnetites which if properly selected would make suitable mixtures for blast furnace operation. Limestones of good quality and ample in quantity are present. In this region also is found quartzite for manufacturing silica bricks. There is an abundance of water power, and the Crow's Nest Coalfield is within reasonable economical distance from a central point that could be decided upon as the operating centre to assemble and convert these minerals into finished iron and steel goods.

It is stated that the Prince Rupert district is worthy of every consideration and that the iron ore zones of that part of the Coast should have minute consideration. The Louise Island deposit is thought to be of special importance, and Mr. Williams attaches a special report on that property. It consists of four claims, two of which have been developed by numerous large and small opencuts, as a result of which work it is said to be probable that the area is altogether underlaid with ore without any intervening country rock. Ore from this source, it is suggested, might be made the basis of the undertaking, the product being supplemented by ores brought from a distance.

Ore on Pacific Coast in Mexico and Oregon

In this connection reference is made to two other important ore fields outside the Province, one a large deposit at San Vicente on the peninsula of lower California, Mexico, and the other an important soft ore field, rich in iron and very easily reduced, which has recently been discovered in the neighborhood of Portland, Oregon. Exploration and development work now is being actively carried on in this region.

That there is a great opportunity for an iron and steel industry on the Coast is declared by Mr. Williams to be shown by the following facts: On the shores of the Pacific Ocean there is a large population, little competition, highest priced iron market in the world, the necessary raw materials of superior grade, water transportation, immense water powers, and an excellent climate.

He concludes by affirming that British Columbia's possibilities as an iron and steel production centre have impressed him and that there now is an unparalleled and unique opportunity for whoever is first in the field, whether the project be undertaken under the auspices of the Government or by private enterprise.

The body of Mr. Wiliams' report is taken up by detailed statements regarding the character of the iron ore deposits visited, the economic suitability of the ore of the Coast and of the Interior, the coal deposits of British Columbia, the cheap and abundant electrical energy available and the limestone and other material available for fluxing and refining purposes. The question of the markets also is discussed and Mr. Williams concludes from the information available to him from various sources that there is a sufficient demand to absorb the output of a good-sized plant.

Mr. Williams and his assistants visited iron ore deposits in the following districts: Harrison Lake, Gordon River, Texada Island, Alta Lake, Queen Charlotte Group, (Louise Island), Burnaby Island, Fanny Bay, Kamloops, Seymour Inlet, Waneta and district. They examined limestone on Texada Island and went into the coal supply question in the Crow's Nest and Nicola Valley regions. Exhaustive reports are appended on all the iron ore deposits seen and some interesting notes are given dealing with the coal supply of the Province.

Coking Coal and Hydro-electric Power Available

Regarding the coal it is stated that there can be no doubt as to the coking qualities of the coal of Nicola and the Crow's Nest. Not only can the coke be produced but the coals lend themselves readily to by-product oven carbonisation resulting in a good coke and high residual yields. Only one adverse criticism is made, and that is, that compared with the best fuel the ash content is occasionally somewhat high, but it is not too high for the successful smelting of high grade ores containing often 64 per cent. or even a higher percentage of iron.

Concerning water powers, Mr. Williams says: "In a country like British Columbia, where abundant electrical power can be obtained from the numerous and plentiful water falls that are such a feature to the Province, it would be advisable, wherever possible, to drive most of the machinery from such source of power. This would guarantee an almost uninterrupted operation of the different sections of the works and would bring about the utilization of the spare gases from the coke oven and blast furnace plants for steel smelting and for re-heating ingots and blooms, thus obviating the installation of costly electrical generating plants and also the erection of large batteries of gas producers. There are very few iron and steel concerns in the world that are the fortunate possessors of such sources of hydro-electric energy in addition to plentiful supplies of high-class coal."

An approximate estimate is given of the cost of establishing an iron and steel works capable of producing 125,000 tons of pig-iron per annum and 120,000 tons of finished steel. The total, exclusive of the cost of purchasing properties and of the cost of coal mining equipment, is placed at $15,592,000. It is figured that it would take four years before a plant of this magnitude could become productive and revenue producing, so that the capital expenditure referred to would be spread over four years approximately as follows: First year, $2,000,000, second year, $3,600,000, Third year $5,000,000; fourth year, $4,992,000. These calculations are given with the explanation that an accurate estimate of cost of plant without obtaining actual tenders is impossible when prices are fluctuating as now is the case. It is thought likely that there will be a reduction in the near future in the market prices of the materials required, so that a reduction in the estimate may be expected.

The United States consumes about 22,000 million gallons of petroleum annually, against 1,400 million gallons for Great Britain and another 1,500 million gallons or so for the rest of the world. Canada's share is about 100 million gallons.

Arsenic in the U. S. During 1922

Output Reported by the United States Geological Survey

The production of refined and crude arsenic in the United States in 1922, according to an estimate by V. C. Heikes, of the United States Geological Survey, amounted to 10,947 short tons. The sales of crude arsenic amounted to 1,366 tons. All the crude arsenic sold was used in making sodium arsenate, a weed killer, either at the place of manufacture or at places nearer the consumer. The production of refined white arsenic having a purity of 99.5 % or more amounted to 9,581 tons, valued at 1,486,000, or 7 3-4 cents a pound. The stocks of domestic arsenic on hand October 1 were reported as 1,230 tons, and the quantity to be made between October 1 and May 1, 1923, was estimated at 3,400 tons.

All Kinds of Arsenic and Uses

The largest users of refined arsenic are the manufacturers of insecticides, who began to buy it in quantity during October, while the prices were rapidly rising. Most of these manufacturers that reported to the Survey used the greater part of their purchased domestic and foreign arsenic in making lead arsenate. In 1922 about five times more lead arsenate was made than all the other arsenical compounds put together, including calcium arsenate, Paris green, and Bordeaux mixture. The reports indicate that during the period from October 1, 1922, to May 1, 1923, the output of calcium arsenate will be larger and that of lead arsenate may be somewhat smaller than heretofore. The makers of plate glass bought their usual quantity of refined arsenic, about 1,000 tons.

Manufacturers

Six western smelting plants that handle copper and lead ores and are equipped with arsenic refineries made white arsenic, crude and refined, in 1922. The American Smelting and Refining Co., which operates the plants at Globe, Colo., and Tacoma, Wash., reported the largest output. The Anaconda Copper Mining Co. had some difficulty in getting sufficient labor to operate at greater capacity its ore-reduction plants at Anaconda, Mont., but reported the second largest output of refined arsenic and the largest output of unrefined arsenic. At the plant of the United States Smelting, Refining and Mining Co. at Midvale, Utah, the output consisted of refined white arsenic, of which a normal quantity was sold. All the company's crude material was worked up into sodium arsenite solution, many thousands of gallons of which was distributed to railroad companies for killing weeds on rights of way. this weed killer is also made in large quantities by the Chipman Chemical Engineering Co., which purchases crude arsenic for shipment to several of its plants in eastern and western States.

Prices

The price of white arsenic in New York in 1922, as quoted by the Oil, Paint, and Drug Reporter, ranged from 6 cents a pound in January to 15 1-2 cents a pound in December. In July the price was 7 3-4 cents, in August it suddenly jumped to 8 1-2 cents a pound, just as the manufacturers of insecticides decided to buy, and it rose rapidly until December. The average price per pound to consumers, however, seems to have been between 7 and 7 3-4 cents, and the maximum price for wholesale lots is understood to have been 8 1-2 cents. Contracts were said to have been made in October for German and Japanese arsenic, to be delivered in November and December, at 9 1-2 to 10 cents a pound, but dealers predict still higher prices at the beginning of the insecticide season, next spring. Lead arsenate, as paste, was quoted at 8 to 14 cents a pound. But arsenic was quoted at 12 to 13 cents a pound, and the quotations on calcium arsenate ranged from 11 to 20 cents a pound and at the end of November 10 to 12 cents was bid. Elemental arsenic was quoted at 17 cents a pound.

Increased Use for Killing Weeds and Insects

The use of arsenic in the United States and abroad in weed-killing compounds has increased during the last year. In the Southern States the cotton-boll weevil is being fought with calcium arsenate, of which about 8,000 tons was distributed to the cotton growers in 1922. According to reports received at the Delta laboratory of the United States Department of Agriculture at Tallulah, La., no calcium arsenate remained in the warehouses after September. B. R. Coad, in charge of that laboratory, reports that the demand for calcium arsenate in 1923 is expected to be twice as great as in 1922. The use of arsenic as a larvacide in mosquito-control work is being extended in the malarial region of the South.

Cause of Shortage of Supply

Though the unusually large demand for arsenical compounds for use as insecticides is doubtless the principal cause of the shortage of arsenic there are a number of other causes. Among these are the reduction in the quantity of copper ores treated at Anaconda, Mont., and at Tacoma, Wash., the small supply of arsenical dust from the lead smelters in Montana, Utah, and Colorado, and the decrease in the imports from Canada, Japan, and Mexico. The present demand for arsenic amounts to 12,000 short tons a year, whereas the supply available in 1921 from both domestic production and imports amounted to only 6, 455 tons.

Some New Developments

The arsenic plants at smelting works in the United States have an annual producing capacity of 18,300 tons of white arsenic, but their actual output must depend largely on the plans of two smelting companies that contemplate reducing ores and speiss directly for their content of arsenic. At Toulon, near Lovelock, Nev., arsenical ores were reported to have been successfully treated and to have yielded some white arsenic in 1922. The owners of this plant expect that it will produce considerable arsenic in 1923. The American Arsenic Co., at Gold Bar, Wash. was producing red arsenic, (realgar) in commercial quantities in 1922, according to a report from the company's engineer. The milling plant on the property has been equipped with a flotation unit and turns out over a ton of powdered realgar a day. The Salt Lake Insecticide Co. is erecting at Salt Lake City a plant for making arsenical compounds directly from ore. The owners estimate that the plant will make a daily output of about 15 tons of calcium arsenate. All the ore to be treated is to be mined at Gold Hill, Utah, from the largest known deposit of basic iron arsenate in the United States.

Two large, new generators are to be added to the hydro-electric plant at Victoria Falls on the Zambesi River, Africa, to supply the increasing demand of the Rand gold mines.

DEVELOPMENTS IN THE MANUFACTURE OF TITANIUM DIOXIDE

A Competitor of White Lead

It has been known for several years that a white titanium pigment was being manufactured in America (BXX Titanox of the Titanium Pigment Co., Niagara Falls, N. Y.) and in Norway (the "Kronos" titanium white of the Titan Co., A S. of Fredriksstad). Particular attention has been directed to these titanium white pigments by the appearance of two papers—one titled "Titanium White: Its Production, Properties, and Use," by Messrs. W. H. Washburn and J. McGougan in the Proceedings of the Paint and Varnish Society (Session 1920—21, No. 3, pp. 41 to 61); and the other, an article on the same subject, by Mr. Noel Heaton in the Journal of the Royal Society of Arts (Vol. LXX, No. 3,631, for June 23, 1922, pp. 552 to 565). There is little doubt that this new pigment has very valuable properties and an attractive future before it. It must, however, be made clear at this stage that the brands of "titanium white" pigment on the market consist normally of about 25 per cent. of pure titanium dioxide mixed with 75 per cent. of barium sulphate (barytes). In some cases, owing to the extreme chemical inertness of the titanium dioxide in the vehicle (usually linseed oil) it has been necessary to add considerable amounts of zinc oxide.

It is claimed for titanium white pigment that (1) it is of dazzling whiteness; (2) it consists of particles of exceeding fineness; (3) it is light in weight; (4) of great permanence, owing to its inertness, either by exposure to acid fumes, fierce glare, or sea water; (5) it is non-poisonous; (6) weight for weight it is said to have nearly three times the obscuring power (opacity) of white lead; and (7) owing to the above qualities it works well, spreads more evenly, and is more durable than any other white paint. The above remarks apply to "titanium white" as distinct from pure titanium dioxide. The drawback has been the great cost of this pigment, the "Standard" quality of the Titan Co. being recently quoted at £50 c.i.f. British port, packing included. The "Extra" quality, containing more titanium dioxide, is quoted at £75 a ton.

The raw materials from which the pure titanium dioxide is prepared are the minerals rutile and ilmenite. Large deposits of rutile are not common, whereas considerable deposits of ilmenite are known. For example, the beach iron sands of certain parts of New Zealand are highly titaniferous, and the monazite sands of the Travancore coast in South India contain nearly 70 per cent. of ilmenite. The quantity of ilmenite in the latter deposits is estimated in hundreds of thousands of tons. It is on cases such as have been cited above, where the ilmenite is obtained as a by-product in the recovery of another substance, that attention has been concentrated.

The question of using the ilmenite in the monazite sands of Travancore has been very carefully considered by those interested in that branch of the Indian mineral industry. They have been faced with an exceedingly dull monazite market for the past eighteen months, and there is no immediate prospect of a trade revival in this mineral. This, it appears, is due to the fact that considerable stocks of monazite exist in Germany—enough, so it is reported, to supply thorium nitrate for the manufacture of gas mantles for the next two years. The cheapness of the German incandescent gas mantles is at present proverbial, consequently the monazite producers have been looking for some other means of maintaining their business. In these circumstances the manufacture of pure titanium dioxide has presented a solution. The process, as recently devised, is simple, and requires high-grade ilmenite in large quantities, cheap sulphuric acid and fuel to make it commercially profitable. The prepared substance has already attracted the attention of dealers and makers of paints and varnishes. A great deal of work has been done, and although it is too early to disclose the developments which are in progress, it is anticipated that a well-laid scheme, involving firms of good name and strongly-entrenched position, will presently emerge. It is estimated that with the existing price of materials, wages, and assembly costs the pure titanium dioxide, which is now being prepared in a semi-commercial manner, will be available at less than £30 a ton. This price is considerably below that of white lead or zinc white.—London Mining Journal.

A LITTLE TALK ON THRIFT

By S. W. STRAUS, President American Society for Thrift

A great deal has been said and written about the value of enthusiasm, and, while we must not under estimate its place in our personal lives or in our business activities, it is well to bear in mind the wisdom of Goethe's observation, that "enthusiasm is of the greatest value, when we are not carried away by it."

Even in the matter of saving there is such a thing as being carried away by enthusiasm. The miser is an example of this. In order to save and get ahead steadily it is vital that we always keep our feet on the solid ground of prudence.

To be effective, saving must be continuous. The person who pinches and saves every possible penny for a short time and then gives up and quits, will never reach the goal of independence or success. Therefore, it is well always to have in mind the matter of moderation. Saving a reasonable amount regularly gives ever increasing stabilization and strength.

When we are strong and well we are apt to pay little or no attention to matters of health. Then if we become ill we suddenly become greatly interested in the care of our physical being and we feel that when we recover we will never again allow ourselves to become neglectful.

It is the same way regarding financial matters. In the vigor of youth or in times of great prosperity, we are apt to disregard the value of thrift. We drift along from day to day and year to year without making preparations for the future. Then suddenly some misfortune happens and we find ourselves confronted by the stern realities of financial impairment. Possibly we have lost our position through illness or perhaps the source of our income is unexpectedly wiped out. Then we think of thrift and make up our minds that if we ever become prosperous again we shall not neglect to put aside a portion of our earnings for the future.

Being thrifty does not mean that we must be an extremist in the matter of saving money or in giving up rightful pleasures. Cultivate moderation. Do not save to the point of being a miser, and to the exclusion of the various uplifting elements that should be a part of our lives.

On the other hand we must use moderation in the matter of pleasure and out of our earnings make sure that we are providing for the lean days that are sure to come

The Mining Districts

BY THE JOURNAL'S CORRESPONDENTS

NORTHERN ONTARIO

Staking Gold Claims in Quebec.— Claims totalling approximately 3000 acres have been staked in the Townships of Fourniere and Malmartie in Quebec, where several discoveries are reported to have been made. One find is understood to have a width of 20 feet. The stakings are about 60 miles east of the Ontario border and in the same general formation as that of Rouyn Township. Staking in the Rouyn district continues, despite the very cold weather. A road is now being cut from the Union Abitibi Mines, which will greatly facilitate assessment work. The most important discovery so far is known as the "Powell Vein", which is understood to run approximately $6.00.

Power from Montreal River.— It is understood that as part of the project for furnishing power to Porcupine and other camps from Indian Chutes on the Montreal River, a motor road will be construeted following the general direction of the transmission lines .This road, in addition to providing for an efficient patrol of the transmission lines, will result in opening up some promising districts and will mean a good road betwene Cobalt and Porcupine. Good progress is being made with the installation of the first units, to generate 2000 h. p. Concrete work is practically all finished and the machinery is on the ground ready for installing, and it is expeeted that it will be possible to turn over the first unit about the first of March. Following the recent underwriting of $800,000 of bonds of the Great Northern Power Cmopany, other units will be installed which will bring the total capaeity of this plant up to 6000 h.p. While the company may be able to develop 6,000 h.p. in times of high water, a good many mine managers are wondering what will happen when the water is low. Few people seem to realize that Northern Ontario has a comparatively small precipitation. Following the extremely heavy run-off in the spring, when it is impossible to conserve all the water, there is, as a general rule, very little precipitation until the following fall. This results, almost every year, in a shortage of water during the summer months. The plant of the Northern Ontario Power Company at Ragged Chutes on the Montreal River, has a capaeity of over 3000 h.p. It is lower down on the Montreal River and has 600 square miles more drainage area than the plant of the Great Northern Power Company, and in addition has storage in Lady Evelyn Lake. During periods of low water, however, the capacity of this plant has fallen to 1000 h.p., and unless the Great Northern Power Company has a large storage capacity it may suffer from the same conditions.

A London View of Canadian Mines.— J. H. Curle's recent artiele, regarding the apathy of English investors towards Northern Ontario gold mines, has aroused a great deal of interest and comment. Mr. Courle was of the opinion that next to the Rand the most important gold mining area of the near future would be Northern Ontario, and he appealed to the mining companies in London to participate in these mines. An English viewpoint is that our method of organizing companies does not appeal to the English investor. It is stated that our properties are capitalized for large sums, with the vendors taking a large proportion as purchase consideration, leaving the remainder to be issued at a discount for the purpose of providing funds to explore the properties, and it is suggested that we should change our methods in order to attract English capital. The methods of financing companies, to which this Englishman objects, certainly have disadvantages, but they appear to be suitable to this country and to the conditions in the United States and Canada, from which most of the capital is derived. It would appear to be better for the English interests to get in early and then they could adopt any scheme they liked that would be more suitable for the English investor.

Shining Tree Consolidation.— At a recent meeting of the newly organized Shining Tree Consolidated Mines Company, it was decided to purchase shares in several companies, on an exchange basis, as follows:—

1 Shares of Consolidated for 4 shares of Wakenda, Algonquin, West Tree and Wasapika.

1 Share of Consolidated for 2 shares of Atlas and Churchill.

2 Shares of Consolidated for 3 shares of the Miller-Adair.

Shares in the Buckingham Mines are also to be taken up by the new company. The Shining Tree Consolidated and practically all companies operating in the West Shining Tree field, are making extensive use of Dr. Harvey Weed's report on several of the mines. It is to be noted, however, that while these reports are extensively referred to, they are not quoted, and the casual reader would gather the impression that Dr. Weed had whole-heartedly endorsed the several properties he had examined. While it is probably going too far to allege misrepresentation, there is no question that Dr. Weed is inferred to have reported much more favorably than he did. In one case in particular, while Dr. Weed's report advised a limited expenditure, he does not show that either by diamond drilling or on the surface any commercial ore-body has been found, and he advises further work solely on account of some very spectacular ore that has been found in small quantities.

Porcupine.— The Vipond is understood to have made a good discovery on the 1000-foot level, where it is reported that 8 feet of $32.00 ore has been cut.— The Goldale is continuing development and exploration work on the 500-foot level, and is getting encouraging results. No ore in commercial quantities has yet been found but it is thought that the drifts may be on the apex of an ore-body.— Thompson-Krist shareholders have decided to re-purchase the company's claims from the Porcupine Mines. The latter company was formed to take over and operate the Thompson-Krist and the Porcupine Crown.

Kirkland.— At the recent meeting of the Teck-Hughes, which was held in New York, no announcement was made regarding the retirement of the bonds or the commencement of dividends. It was stated that these were matters which would be dealt with at a directors'

meeting. Developments at the property continue to be favorable and the new ore on the 700-foot level was stated to be the best that has yet been discovered in the mine, and it was thought that the possibilities with depth were very good.

NORTHWESTERN ONTARIO

Activity at Mikado Mine.—Christmas finds the lake of the Woods wearing its accustomed garb, and with ice strong enough to carry a load. Work is going on at the Mikado, with seventeen men or so working underground and another half dozen filling a cord-wood contract. With this exception there is no actual mining in progress. Yet it may be that one or two properties will make a start next spring. Mr. Charles Brent, an old-timer in the district, has been here, and rumor says he was engaged by Buffalo capitalists to look over the state of affairs at the old Scramble and Champion mines, and to ascertain whether power could be obtained from the Backus-Brooks outfit, and at what cost. Brent himself made no statements, excepting that he expected to be back next spring.

Red Lake Claims.—One hundred and fifty claims in all were staked in the Red Lake district last autumn. No one is there now, but a good deal of assessment work will be done after open water. Mr. Stanley McLeod discovered a very large body of low-grade ore, not more than a couple of thousand feet from the discovery claim, from which much is hoped. If it should prove to have promise, after a little more testing, McLeod has plenty of capital behind him, enough to put a railway in should that be deemed advisable.

Gold at Red Lake.—The concensus of opinion is that Red Lake is a gold district with silver as a minor accessory; it seems to have been by a mere freak of chance that the white metal was the first to be discovered. The original find, in any case, is apparently a small matter, of little commercial importance, by comparison with later discoveries of the more precious metal.

NOVA SCOTIA

Co-operative Settlement of Disputes not in Favour.—Not being satisfied that the workmen of the Sydney Steel plant were averse to co-operating with the Company in carrying on business, and settling disputes arising in the progress of work through a Workmen's Committee, it was decided to take a plebiscite on the question in the steel plant. This was done last week and the vote stood 1000 for the measure and 1500 against it. This does not necessarily mean, however, that the workmen are in favor of One Big Union, as repeatedly stated by the extreme wing of the Labor party. It is simply a pronouncement against the new principal of Industrial Co-operation proposed by Superintendent Bischoff. It is regrettable that his proposal, which looked towards a peaceful settlement of disputes and working together along lines leading to successful operations at the steel works for the good of the community, should be set aside. That this should be accomplished by the action and agitation of would-be leaders of the people who fear that sane rather than insane methods should characterize the affairs of the steel workers, gives food for thought. With 1000 men employed who fully believe that the steel industry will thrive best by an open recognition of the identity of interest between labor and capital, there is a guarantee of success, no less great than that achieved by Gideon's little army of 300, after it had been relieved of its chaff through the winnowing process of its leader. May we not look for like results in this case?

Iron Mine Unwatered.—Dominion No. 3 Mine, Wabana, Newfoundland, lately put into operation, contained 43,000,000 gallons of water last June. On the 26th of that month the work of pumping out the mine began and was completed on September 30th. Only one pump, No. 5 three stage Cameron horizontal type centrifugal, was used.

Iron Ore for Export.—The iron ore trade from Newfoundland to Europe was very good during the year just ending. It is understood that a much larger amount of ore will be shipped to European ports in 1923. For the purpose of putting a better quality of ore on the market, free from refuse material, additional picking belts will be installed, and those now in use be made wider. The Dominion Iron and Steel Company is doing its utmost to give the best quality of material to its customers.

The Steel Plant.—The best indication of the prosperity at Sydney Steel plant is the blowing in of the third blast-furnace and the increase in the force, which now numbers 3200 workmen.

Coal Shipment from Louisburg.—The Louisburg coal piers are now in good condition, having undergone extensive repair. They will be equal to the large amount of coal passing over them during the winter.

BRITISH COLUMBIA

The Late J. D. Mackenzie.—To mining men of British Columbia generally, and in particular to members of the British Columbia Branch of the Canadian Institute of Mining & Metallurgy, the news of the death of J. D. Mackenzie, head of the Canadian Geological Survey in this province, in a Montreal hospital on December 15th last, was received with feelings of deep regret. It is not enough to say that Mr. Mackenzie was popular in the west. All who knew him appreciated him as a competent official and as a genuine man. He took a leading part in the proceedings of the last annual meeting of the Canadian Institute of Mining & Metallurgy held at Vancouver in November. In debates his voice was listened to with close attention and his views carried great weight. In the lighter moments of the meeting, when members were assembled for amusement solely, his was one of the central and most popular personalities. Although possessed of strong convictions he made few enemies and made many real friends. His death is a distinct loss to the mining fraternity of Canada and especially to the Province of British Columbia where he had been occupied professionally since returning from the war. Mr. Mackenzie was 31 years of age, was born in Cape Breton, put himself through the Massachusetts Institute of Technology, became attached to the Canadian Geology Survey, and volunteered [illegible] front as a private in the 185th Cape Breton Highlanders. He had a distinguished career overseas, rising to the rank of Captain, receiving the Military Cross, and finally being invalided as a result of a machine gun wound. It was the latter that caused his death, for it never completely healed. He married in British Columbia Miss I. M. Lord, of New Westminster, who served overseas as a nurse. The last work he did in the West was a geological survey of the coalfields of Vancouver Island.

No Action on Steel Company Proposal.—The British Columbia Legislature has prorogued without passing enabling legislation in connection with the Government's undertaking to guarantee the bonds of the Coast Range Steel Ltd. up to $4,000,000 providing the Dominion and Imperial Governments do likewise. Premier Oliver and his colleagues are on record as being willing to assist, to the extent indicated and under the conditions intimated, in the establishment of an iron and steel industry in the Province. The position was taken, however, that lacking more definite word from the Federal and Imperial authorities the time was not opportune to ask the Provincial Legislature to take action. It also was pointed out that considerable money is being spent by the Province in the exploration of its iron ore resources and that it would be well to await detailed reports of the result of this work.

Promising Silver Property.—The Slocan Silver Mines Ltd., R. A. Grimes, manager, has installed on the "McAllister" property, Three Forks, a Pelton wheel and a compressor. A 1500-foot crosscut is being driven, designed to give 450 feet additional depth on the vein, the principal ore shoot of which is 700 feet in length in the present workings. It is stated that the McAllister will prove one of the important Mines of the Interior if the crosscut refers to accomplishments what the management expects.

Cold Weather Freezes Concentrator.—The Alamo concentrator, Alamo B. C., Clarence Cunningham, manager, has been closed down temporarily owing to a spell of exceedingly cold weather. With the thermometer 14 degrees below zero at Alamo the hoist became unworkable, the water freezing at the valves.

The Sheep Creek Gold Deposits.—Connection has been established between the workings of the Nugget and the Motherlode Mines, Sheep Creek, through the new workings on the former property, Dominion Mountain. Superintendent Lakes states that a complete change in methods of operation will follow, the camp being moved from the Motherlode to the other side of the mountain, adjacent to the old Nugget tunnels. Here there is a large quantity of milling ore, which will be stoped out and transported through the Motherlode workings to the mill. The mill was shut down in November. It will be re-opened next summer.

Fuel Oil Cheaper than Coal.—An effort was made during the British Columbia Legislative Session, which has just closed, to amend the coal Mines Regulation Act in order that the coal miners might appoint representatives on Gas Committees other than from their own numbers. They wanted the privilege of nominating outside men. The majority of members of the House, however held that such latitude might lead to abuses that would seriously affect the industry, and the amendment was defeated. In the debate, attention was drawn to the serious results of the large importations of fuel oil into the Province from the United States. It was said that 90,000 tons of British Columbia coal per month was being driven from the local markets. Local coal was unable to meet the competition. One large mine already had been closed down on Vancouver Island and the time had arrived for the Dominion to impose a heavier duty on fuel oil coming from outside in order that the provincial coal industry might be saved.

The known iron ore deposits of China have a reserve supply of 700 million to 1000 million tons, which is about one-quarter the reserves of the United States, or four fifths those of Great Britain.

There are at present 275,000 producing oil wells in the United States, owned by 14,000 different interests, and the approximate output per day is 1,500,000 barrels.

INDEX TO MINE AND MILL SUPPLIES

Addresses of advertisers whose names appear in the following classified index, may be found upon reference to their advertisements. An alphabetical index to advertisers will be found on the page facing the inside back cover. The following regulations apply to all advertisers;—One-eigth page, every issue, three headings, one-quarter page, every issue, six headings; one half page, every issue, six headings; one half page, every issue, twelve headings, full page, every issue, twenty-four headings. Buyers who are unable to find in the classification heregiven such machinery or supplies as they desire are invitedto write Service Dept., Canadian Mining Journal, Gardenvale, Que., who can in all probability, refer them to proper sources.
