In the Township of Portland West,

FOR SALE.

Lots 25, 26, 27 and 28, in the 3rd range. Some excellent surface shows have been uncovered on these lots and only require capital for developing. Price and particulars given at the office of the MINING REVIEW.

NOTICE.

TENDERS will be received at the Department of Inland Revenue until Monday, 16th November, prox., from parties desirous of leasing the privilege of ferrying across the River Ottawa between Buckingham and the County of Ottawa, in the Province of Quebec, and Cumberland, in the County of Russell, in the Province of Ontario, in accordance with the terms and under the conditions set forth in the regulations, copies of which can be procured from the Inland Revenue Department at Ottawa or postmasters at Buckingham and Cumberland.

Each tender must state the amount which the party tendering is willing to pay per annum for the privilege referred to, which amount will be payable in advance, the terms of the lease being for five years from the 1st May, 1886.

Each tender must be accompanied by a cheque marked "Good" on one of the chartered banks doing business at Ottawa, for one-half the amount of the per annum tender. This amount will be credited on account of the first year's rent in the case of the accepted tender, and all other cheques will be returned, except in the event of withdrawals, in which cases no refunds will be made.

All communications must be addressed to the undersigned and endorsed on the envelope "Tender for the Buckingham and Cumberland Ferry."

WM. HIMSWORTH,
Secretary.

Department of Inland Revenue,
Ottawa, October 26th, 1885.

GRAND COLONIAL

Exhibition in London, Eng.
1886.

FIFTY-FOUR THOUSAND FEET RESERVED FOR CANADA.

First Royal Exhibition Commission Since 1862.

THE Colonial and Indian Exhibition to be held in London, England, commencing May 1st, 1886, is intended to be on a scale of great magnitude, having for object to mark an epoch in the relations of all the parts of the British Empire with each other.

In order to give becoming significance to the event, a Royal Commission is issued for the holding of this Exhibition, for the first time since 1862; and His Royal Highness the Prince of Wales has been appointed President by Her Majesty.

The very large space of 54,000 square feet has been allotted to the Dominion of Canada by command of the President, His Royal Highness.

This Exhibition is to be purely Colonial and Indian, and no competition from the United Kingdom or from foreign nations will be permitted, the object being to exhibit to the world at large what the Colonies can do.

The grandest opportunity ever offered to Canada is thus afforded to show the distinguished place she occupies, by the progress she has made in Agriculture, in Horticulture, in the Industrial and Fine Arts, in the Manufacturing Industries, in the Newest Improvements in Manufacturing Machinery and Implements, in Public Works by Models and Designs; also in an adequate display of her vast resources in the Fisheries and in Forest and Mineral wealth, and also in Shipping.

All Canadians of all parties and classes are invited to come forward and vie with each other in endeavoring on this great occasion to put Canada in her true place as the premier colony of the British Empire, and to establish her proper position before the world.

Every farmer, every producer, and every manufacturer, has in erect in assisting, it having been already demonstrated that extension of trade always follows such efforts.

By order,

JOHN LOWE,

Sec. of the Dept. of Agriculture.
Ottawa, 1st Sept., 1885.

MINES AND MINERALS.

Developed and Undeveloped Mines and Minerals of Commercial Value
BOUGHT AND SOLD.

PROPERTIES EXAMINED AND ANALYSES MADE OF ORE OF EVERY DESCRIPTION.

A Competent Expert is permanently engaged for the purpose of making Unprejudiced Reports on all Mines placed in our hands for Sale, such reports being at all times open to intending purchasers for examination.

Phosphate, Iron, Iron Pyrites, Copper, Asbestos, Mica, Plumbago, Gold and Silver Mines, and Marble and Sandstone Quarries, For Sale.

MINERAL LANDS EXAMINED AND REPORTED ON BY OUR EXPERT; ALSO, ANALYSES OF MINERALS OF EVERY DESCRIPTION MADE BY A COMPETENT ASSAYIST.

Correspondence with Owners of Mines and Capitalists desirous of investing is most respectfully solicited.

Address all Communications to

FOR SALE

Valuable Phosphate and Farming Property,

In the Township of Templeton, County of Ottawa, Province of Quebec, adjacent to the celebrated phosphate mines of McLaurin and Blackburn, Jackson Rae, J. H. Post, and others, consisting of

LOT 14, RANGE 13 AND N^o 14, RANGE 9, CONTAINING 300 ACRES.

Dwelling-house, Barns, Stables and Out-houses, in good order, on the property, in proximity to a good phosphate opening from which several tons of high-grade phosphate have been raised, and where mining operations can be at once started.

The property has been partially prospected and several promising out-croppings of phosphate have been exposed. It has been pronounced a valuable phosphate location by miners working in the vicinity, and satisfactory reasons can be given for offering it for sale.

The owners, Messrs. Pearson, who hold a clear title to the lots, will sell them in fee simple, or the mining rights only.

Cost of transportation from the property to point of shipment will not exceed \$2 per ton.

For terms and full information apply on the premises, or to

THE POSTMASTER,

East Templeton, Pro. Que., Canada.

FOR SALE.

DEVELOPED

PHOSPHATE MINE

ADJOINING THE FAMOUS LITTLE RAPIDS MINE IN PORTLAND EAST.

THIS location has been pronounced by experienced practical miners one of the most promising apatite producing properties in the district. There are over TWENTY SURFACE EXPOSURES OF GOOD PROMISE, and one deposit now being worked that proves an extensive body of phosphate at a depth of FIFTY FEET.

Price reasonable and satisfactory reasons given for selling.

Full particulars obtainable at this office.

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Engine House, Toronto, Ont." will be received at this office until MONDAY, 25th instant, for the erection and completion of

AN ENGINE HOUSE,

At the Examining Warehouse,
Toronto, Ont.

Plans and specification can be seen at the Department of Public Works, Ottawa, and at the office of D. B. Dick, Architect, Toronto, on and after WEDNESDAY, 9th instant.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted bank cheque, made payable to the order of the Honorable the Minister of Public Works equal to five per cent. of the amount of the tender, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

A. GOBEIL,

Secretary.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

There are, at the present time, substantial indications that capital is seeking investment in mines and mineral lands, and those mines and mining locations that possess real value will be favourably regarded. Unquestionably good properties are in demand, but as capitalists have learned to discriminate, valueless properties need not be presented to them.

The discoveries that have been made during the year just closed indicate, in some degree, the magnitude of the mineral resources of this Dominion. In the provinces of Nova Scotia, New Brunswick, Quebec, Ontario, the North-West Territories, and in British Columbia, important discoveries have been reported and verified, and it is to be hoped that the fortunate discoverers will see how greatly it would benefit themselves and the mining industry of Canada were they to offer reasonable inducements to capitalists to come forward and assist in developing these mineral deposits in order that they may be made productive and profitable.

On another page will be found an interesting summary, by Edwin J. Ball, Ph. D., of the progress made in mining during 1885. Mr. Ball's reputation as a Metallurgist and the position he occupies in the Royal School of Mines, London, England, must render anything from his pen of interest to our readers.

We had hoped to have been in possession, before now, of a complete statement of the asbestos mining industry of the Eastern Townships for the season of 1885, including an account of the operations at the various mines, their total output and the exportation. It has not yet reached us, but will undoubtedly appear in our next issue.

Towards the closing of the past year there were indications of an upward movement in the iron market of the United States. Between the 1st and 7th of December there were enquiries on the Cleveland, O., market for 60,000 tons of pig iron, of which 40,000 tons were Bessemer. Under this active demand prices advanced materially, and are still steadily creeping up.

In the same market, during the year just closed, more iron ore was sold than in any former year in the history of the trade.

The Colonial and Indian Exhibition to be held in London, England, commencing on the 1st of May next, will afford Canada a great opportunity to exhibit to the world at large the vastness and variety of her mineral resources. If there is not a creditable display of the product of Canadian mines, the mine owners will be held responsible, as the Minister of Agriculture, through the Geological Survey Department, has extended to them every facility for forwarding exhibits free of charge.

The fact is beginning to dawn upon the minds of men that the production of mineral is the only legitimate object and purpose of mines or mining operations, and that a sale is not the chief thing to be considered in locating and developing a mining claim. Men also realize that there is a vast difference in the comparative values of a mine and a claim. Capitalists discovered this fact some time ago, and when miners and owners have the same convictions the march of improvement and prosperity will begin.—*Mining Review, Chicago.*

The Metallurgical Association, Limited, is the title of a new company, registered in London, with the large capital of £300,000, in £1 shares, to acquire and work patents. Here is the long-desired "opening" for all metallurgical cranks. The notice speaks of £300,000 as a "large capital;" but it should have been at least £300,000,000; for even that would be a small sum, compared with the inventors' valuation of a few of the grand metallurgical inventions brought to our personal notice, and which have been held back, waiting for just this opportunity to "revolutionize science." We would recommend that the capital be at once increased to at least the figure we have mentioned, and that rules be adopted to secure the equitable and safe division of the dividends, and, in the interest of the strictest economy and safety, that no inventor shall be paid in cash more than ninety per cent. of his own estimate of the value of his invention. The company should have an expert board of managers, composed exclusively of inventors upon whom unappreciative, cold, and heartless scientists have frowned.—*Eng. and Min. Journal, N.Y.*

THE PHOSPHATE TRADE.

The last shipments of phosphate for the season, from Montreal, were made by Messrs. Wilson & Green and Lomer, Rohr & Co. on the 11th November, in S.S. Grassbrooke, to London, amounting to 629 tons, 419 and 210 tons respectively. We give below a statement of all the shipments from the opening to the close of navigation, from which it will be seen they have aggregated 23,908 tons, an increase of 1,765 tons over shipments for 1884. There has been a falling off in the amount forwarded from the Perth and Kingston districts, while the output of the Ottawa County mines has increased 2,055 tons. The prices realized for the year's production have been satisfactory to miners, some of whom have already made contracts for delivery next year at the current prices of the past season, which would indicate that they have been satisfied with the margin of profits these prices have afforded them. The increase in the annual production has not been as great during the past four years as there has been reason to expect, but there has been a steady increase, nevertheless, and it is not unlikely that it will be at a much larger ratio for the season of 1886. The production for the past five years has been as follows:—

1881.....	15,601 tons.
1882.....	17,181 "
1883.....	17,840 "
1884.....	22,143 "
1885.....	23,908 "

showing but a small increase for 1885 over 1884; but it may be said that the output for the season just closed, aggregating close upon 24,000 tons, has been of a higher standard than has ever before been forwarded from the phosphate mines of Canada, the analyses showing it to have analyzed over 80 per cent. Certain shipments from no less than four of the heavy producing mines have assayed upwards of 85 per cent. tribasic phosphate of lime, and we doubt if such results have been obtained at any other phosphate mines in the world.

The American Consul at Ottawa, Mr. T. W. Hotchkiss, in a recent report on the phosphate industry of Ottawa County, addressed to the State Department at Washington, says of Canadian phosphate: "When it was first introduced in the market it was looked upon with suspicion, through a want of actual and reliable knowledge of its value as a fertilizer; but today this state of things is entirely reversed, every pound of the output being contracted for by foreign buyers in advance of production. Being a more concentrated phosphate than is known to exist in any other part of the world, the product of Canadian mines is sought after to bring up fertilizers to a high percentage of phosphoric acid. Regarding the value of this apatite as a fertilizer, a reliable authority states that Canadian apatite contains 91.91 per cent. of tribasic phosphate of lime, according to the most scientific analysis. A comparative table of the composition of certain fluorapatites shows that, with the exception of three limited deposits in the West Indies and one in Spain,

CANADIAN APATITE RANKS HIGHEST.

It may now be said that from no other phosphate mines in the world have shipments been made of so high a standard as have been forwarded from Canadian mines during the past season."

The American Consul refers to recent foreign reports as showing that in those portions of Europe where sugar beet is extensively cultivated—France, Belgium and Denmark—no fertilizer has been found to equal the mineral

phosphate of Canada. In the figures and facts which he quotes in connection with the business in the past, we have observed several inaccuracies; but they are in the main correct—sufficiently so, at least, to serve as data for his report on our phosphate trade, which he recognizes as one of the most important industries of his consulate district. After referring to the various apatite mines worked in Ottawa County, Mr. Hotchkiss points out that the necessity for the use of proper fertilizers is limitless, and must remain so, assuring a demand not spasmodic, but steady, and constantly growing.

PHOSPHATE SHIPMENTS FOR 1885.

LITTLE RAPIDS MINE.

Frequent reference has been made in the *Review* to the constant improvements at the various phosphate mines in the du Lièvre district during the past two years, but at none of them are these improvements more striking than at the *Little Rapids* mine, where everything that ingenuity could devise to facilitate the mining of this peculiar ore appears to have been provided. The buildings, which include commodious boarding-houses, store-houses, supply store, stables and manager's dwelling and office, are complete in every particular and have been substantially constructed with a view to permanency. At the mine nothing is done by hand where it has been possible to introduce steam power. Wherever steam-drills can be used to advantage, there they are at work; steam-pumps, steam-hoists and steam-derricks are employed at the various shafts and open pits, and the condition of the engines, boilers and other machinery gives evidence of careful attention. Other improvements at this mine are worthy of mention, such as, the arrangement of the tramway, which has been so located as to connect all the shafts and pits with a new and commodious cobbing-house, and the substantial and suitable ore-cars. The cobbing-house is well lighted and is heated by steam, and in connection with it an ingenious system of cleaning up the fine phosphate, or separating it from foreign matter, has been introduced. The system itself, which is merely sieving, has always been known in connection with phosphate mining, but at all the other mines it is done by hand, while at the *Little Rapids* the sieves are run by steam and the saving in time and labour, as well as the effectiveness of the work accomplished, is very noticeable. At the cobbing-house are the ore-bins and platforms, arranged to receive the different grades of dressed ore, and thence a tramway leading to the waggon road at base of hill where the phosphate is delivered, loaded into waggons and hauled to point of shipment on the bank of the du Lièvre river. We understand it is in contemplation to extend the tramway to the river, a distance of about half a mile, and with this additional improvement the *Little Rapids* will be equipped in a manner conducive to the raising, dressing and handling of phosphate at a minimum of cost. It is now one of the most attractive mines in the entire phosphate district, not more for the completeness of the equipment than on account of the depth of the shafts and the large bodies of ore in sight in all the workings. The present condition of the *Little Rapids* mine reflects great credit on the

Manager, Mr. George R. Smith, under whose direct supervision all the work above referred to has been done, and who has planned all the improvements and personally superintended the erection and arrangement of the machinery and everything connected therewith.

The Anglo-Canadian Asbestos Company (Limited).

This company has been formed in England and has acquired the asbestos properties at Black Lake, known as the Eureka and Emilie Mines, situated about two miles from the line of the Quebec Central Railway. The capital stock of the company is £50,000 in 25,000 shares of £2 each. The purchase money is £35,000, of which £15,000 is taken in shares, and the vendors, Messrs. Irwin, Hopper & Co., of Montreal, it is said, have expressed a willingness to extend the amount paid in shares to £30,000, at the option of the directors. The company is now putting in machinery at the mines, with the intention of proceeding with mining operations on an extensive scale during the winter. This will be a new departure, as it has been the custom heretofore, to suspend work at all Canadian asbestos mines for the winter months, and the past season was not an exception in this respect, as mining operations were closed down about the end of November. The Anglo-Canadian Company has, however, made contracts for future delivery, which necessitates continuous working at the mine in order that the quantity contracted for may not fall short.

Notes on the Progress of Mining in Europe

BY E. J. BALL, PH.D.,

(Assistant in Metallurgy at the Normal School of Science and Royal School of Mines, London.)

[Written specially for the Canadian Mining Review.]

Among the improvements introduced into Prussian mines in 1885, an account of which has only recently been published, the Haase method of sinking shafts in quicksand seems likely to prove of some importance. It consists in putting down a number of bore-holes communicating with one another around the position chosen for the shaft, and then piping them well, thus forming a protection for the shaft impervious to the sand. Various explosives were tried, and comparative experiments between dynamite and explosive gelatine ended in favour of the latter. Compressed powder was found to be more serviceable in mines than the ordinary variety, and the trials with kinetite gave favourable results.

Various other explosives have been brought into notice during the past year, and they have been tried with more or less satisfactory results; it is claimed for one of them, romite, that it will only explode in enclosed spaces, such as bore-holes; that it does not freeze; and that it can be employed at any temperature. It is a solid, and is said to have a high explosive power.

Messrs. Wickersheimer and Peck propose to enlarge the lower part of a drill-hole by drilling two holes side by side, giving one of them a light charge, and then tamping and firing it in the usual way, the other remaining open. The wall between the lower parts of the holes is blown away, and the holes are cleared by a current of water passed down the empty hole and up the one which has been fired.

Various rock-drills have been reported on, and some exceedingly satisfactory results have been

obtained in German collieries with the Brandt and the Frölich drills.

Experiments which have been made with the lime cartridge appear to show that it is only of importance in the case of fiery pits, where their use gives better results than are obtained by the ordinary mechanical methods.

A very important paper on the "Thick coal of South Staffordshire" has been published by Mr. H. W. Hughes, who gives, for the first time, comparative results, obtained from actual workings, between the three methods employed for mining this seam; square-work, long-wall in one slice; and long-wall in two slices; and he shows that the old square-work system is by far the best, both as regards the percentage of large coal and the freedom from gob fires.

The influence of coal-dust on colliery explosions has been discussed at great length during the past year, chiefly in the Austrian papers, the general opinion being that coal-dust is a very much more important factor in colliery explosions than has hitherto been accepted, and Dr. Hilt in his report on this subject to the Prussian Commission on Fire-Damp gives the results of many hundred experiments which have been made on different varieties of coals. He shows that the character of the explosion is dependent on the nature of the dust, and on the simultaneous presence of gas; and that true coal-dust explosions can explode gas-mixtures, and that, similarly, gas explosions can explode collections of coal-dust. It was further found that while free powder always ignited coal-dust, dynamite shots, and even free-lying dynamite cartridges never set fire to coal-dust alone, and they only did so when upwards of 6 per cent. of gas was present. Wetting the dust was found to be of little use, unless at least one-half its weight of water had been employed.

Numerous safety lamps have been described or tested during 1885, and those employed in the Ostran-Karwin mining district, Austria, have been described at great length by J. Mayer in the *Oesterreichische Zeitschrift für Bergund Hüttenwesen*. Dr. C. Le Neve Foster, in his report on the mining exhibits at the late International Inventions Exhibition, in describing Mr. E. Evans' lamp, states that if it be placed in an explosive atmosphere, the gauze becoming filled with flame, a fine cord is burned through, which, releasing a shield, shuts the lamp entirely off from the surrounding atmosphere, and it goes out before it can lead to an explosion.

Several portable electric lamps have been proposed, but they fail chiefly on account of their weight, and it seems hopeless to look for much improvement in this direction until some very much lighter material is used in secondary batteries than those at present employed.

In several instances the surface works of collieries have been lit by the electric light with considerable success.

Various fire-damp indicators have been brought forward, the simplest being that invented by Mr. Garforth, who uses a flexible india rubber ball, which he fills with the air to be tested, and which is then ejected into the flame of a lamp.

With regard to winding ropes, Dr. Foster states that the locked-wire rope, invented by Mr. Latch, has many advantages over the older forms of wire-rope, especially as regards comparative strength. Several modifications in the methods of winding have also been described.

Wire ropeways have been erected at several mines, more especially in Austria, the one at Raibl having a free span of 700 metres.

The use of electricity as a motive power is gradually coming into use, and a small line has

recently been erected in England in which a number of trucks are moved along a wire ropeway by a current passed through a receiving dynamo attached to the train.

The experiments with the Soda locomotive have been continued in Prussia, but are not yet completed. The Lentz fireless locomotive is based on the one originally designed by Dr. Launm, of New Orleans, and it consists of a boiler provided with an air-jacket and covered with non-conducting materials, which is partially filled with water, into which steam is passed from a generating boiler. The water becomes superheated, and, cooling slowly, gives off steam during a considerable period. The engine is chiefly intended for underground work.

But little of novelty with respect to ore-dressing has appeared, but an important paper on coal-washing plant was read by R. de Soldenhoff before the South Wales Institute of Engineers.

Wire rope has been successfully employed in Sweden in the place of ordinary pump rods; and with regard to deep boring, the bore-hole at Schladebach in Germany is said to be the deepest in existence, having reached, on Sept. 26th a depth of over 1656 metres, the temperature at the bottom being 44° C.

THE HURONIAN MINE.

The opinions of mining experts and men of experience in mining and milling ores are always sought after by mine owners, and those owners who wish to succeed in mining ventures should permit themselves to be guided by the men who have made a life-long study of a business which they are engaging in, perhaps, for the first time. In the case of the Huronian mine, in the gold region west of Port Arthur, Lake Superior district, the company has had the benefit of an opinion, as to the value of its property, from Mr. Charles F. Eschweiler, M. E., of Milwaukee, who was employed as Superintendent of the mine during last summer. Mr. Eschweiler expresses himself in the highest terms as to the richness of the mine, and before retiring from the superintendency he volunteered sound, practical advice to the company for its guidance in the future working of the mine. His opinions and advice have been endorsed by Mr. Richard Crow, of Colorado, who had charge of the company's mill, under Mr. Eschweiler, and who also retired after he had succeeded in putting the mill in proper working order. Mr. Crow's opinions are very plainly and forcibly expressed in the following letter addressed by him to the company's manager:—

Thos. A. Keefer, Esq., Manager of the Huronian Mining Company, Port Arthur, Ont.

DEAR SIR,—Before leaving for my home in the West, I wish to convey to you the very high opinion I have of the Huronian Mine.

In the Western States such a mine would be considered one of great value. It has a vein which, when once properly opened up, can be made to supply a large sized mill. The longer the mine is worked the greater will be the profit derived from it.

The results of your recent mill tests show it to be a mine capable of being made a very large dividend paying concern. Those results can be improved on by abandoning the free milling process and increasing the lift of the present stamps, so that each of your batteries of five stamps will crush about two tons more per day, making the crushed product from each battery about ten tons per day. This would be an important item in working a large mill.

By putting up a new mill with stamps with double issue, and three or four vanners to each battery of five stamps, you could reckon on two batteries of five stamps doing at least as much as three batteries with a single issue.

The Huronian mine vein is very heavily mineralized, much more so than the majority of gold bearing veins. There is a splendid and most convenient site for a new mill close to where your main shaft would be. The water conveniences are admirable and your wood supply abundant. After an experience of over twenty years in the mines and mills of Colorado and the western States, including several months at the Ropes' Gold Mine on the south shore of Lake Superior, I have no hesitation in saying the Huronian mine will compare favorably with some of the best of them, and that it is a most valuable property.

Yours truly,

RICHARD CROW.

SILVER MOUNTAIN.

THE WEST END MINE.

Early in December a shipment of ten tons of ore was made from the west end of Silver Mountain, which created quite a flutter of excitement among the mining fraternity of the town of Port Arthur, who await, with unabated interest, the verdict as to the value of this first shipment from the location.

During last summer a short tunnel had been driven which tapped the vein about twenty feet below the surface outcrop, and from the point of intersection a shaft was sunk to a depth of twenty-three feet. When this work had been accomplished, some intending purchasers visited the property and proceeded to take out a quantity of ore to be submitted to a mill test. The shaft was carried down for some distance, and between the 25th of October and the 21st of November, with but five miners employed, the requisite quantity of ore was obtained. It would be difficult to estimate the value of the ore shipped, even approximately, though it has been stated by some who may be considered fair judges, that it will yield from \$300 to \$500 per ton, in which case it will be a most satisfactory result of less than a month's labor of five men. In addition to the ore shipped, a quantity was raised of a lower grade, which, owing to the cost of transportation, can be made valuable only if treated at or near the mine.

The shaft at the *West End* mine is down thirty-two feet below the tunnel, or fifty-seven feet below the surface outcrop. From the surface to the bottom of the shaft the vein carries good pay ore, but it is unquestionably richest at the lowest point yet reached. The result of the mill test of the shipment of ore above referred to will settle the question of a sale of the property, for or against.

M. J. T.

EAST END MINE.

The following extract from a letter received by a gentleman of Port Arthur from an expert who visited the east end of Silver Mountain shortly after the Cleveland company stopped work, gives an interesting account of the work done. He says: "I looked over the Cleveland company's work to-day, and find that it has all been devoted to the rich little vein, except the shaft on the top of the hill. The upper tunnel starts from a few feet north of the main vein, and runs from it towards the little one for about seventy feet, and then angles towards it for some thirty-two feet. In a few days they

would have cut through to the main vein and seen what it was like, had not the work been stopped. It is a great pity so much time and money should have been wasted in the tunnel and the main vein left totally untested, except at the top, where the chances of getting good ore were so much less. If the company had secured a survey and plan of only about 1,000 feet in the vicinity of their work, as well as of the work done, a glance would have shown how far astray they were, so far as giving the main lode any trial was concerned.—*Port Arthur Sentinel.*

LAKE OF THE WOODS Gold Mining District.

Among the mining districts of Canada none has, perhaps, attracted so much public attention and produced so little tangible result in the shape of successful and flourishing mining concerns as that of the Lake of the Woods. It is some half dozen years or more now since the pioneer prospector, Frank Moore, brought in the first gold-bearing quartz, and from that time on Rat Portage has been enjoying a quiet little "boom" of its own. Its prospects as the centre of a mining district, together with the saw mills that then began to cluster around it, and the advent of the railway, have built it up from a mere Hudson's Bay Company's outpost to a thriving town of no mean pretensions and hopes. There has been the usual influx of gold-hunters, both speculators and prospectors; the usual egress of the disappointed and disgusted, carrying off with them very valuable experience, doubtless, but leaving their money behind them; and the usual percentage of pilgrims to these rocky, rough-pathed shrines of Mammon who have pinned their faith on the place, and having taken up as many claims as they could conveniently persuade surveyors to take shares in payment for the surveying thereof, have settled down as the "ragged millionaires" of the town, waiting with impatience for the propitious turn of fortune's wheel that will enable them to "realize." With all this coming and going and prospecting, the town of Rat Portage has thriven, and bids fair, by an intelligent development of her natural resources, to make for us some day a busy, vigorous city at the western gates of Algoma. Every chain almost of the lake shore and its thousands of islands has been explored in the search for auriferous veins. Hundreds of locations have been taken up in some fashion or another, and half as many have been surveyed and officially applied for; many *bona fide* mines have been started, and many thousands of dollars have been sunk in genuine enterprise; and yet there has been no assuredly successful mine established. Failure or suspension of work *sine die* has been the rule, with one or two exceptions. Expensive machinery has been brought in and expensive buildings have been erected on some locations, only to be pulled down and carried off, or left to take care of themselves, two or three years later. Why is this? There certainly is gold in the country, and some leads carry such percentages of it as, any expert would declare, should authorize mining operations. The men who know the country have confidence in even its immediate future, in spite of these failures. The hard real fact that quartz showing free gold is being constantly brought from different parts of the lake, and that repeated assays have demonstrated that it

is in such quantity as will pay to mine, and the knowledge that similar grade ores are mined successfully in other countries is more than enough to sustain the faith of the believers in the mineral resources of the Lake of the Woods region, in spite of individual failures. If we examine for a moment the cause of these failures and the causes of the general lameness that has characterized mining enterprise in this region hitherto, we shall see that there is no real cause for alarm as regards its prospects as a mineral producing country. First we find that most of the mining schemes set on foot in the Lake of the Woods district were closely associated with the famous land boom in Winnipeg some few years ago, when every chance speculation that offered was eagerly snatched at. Companies were then formed to mine gold on the Lake of the Woods, but before they were well started the boom flattened out, money became scarce, and the mines, after dragging on a half-hearted life for a few months, and getting deeper into debt than into their lead, gradually ceased to evince any signs of life. But not only was this display of enterprise nipped in the bud by the frost of poverty of funds, but had all the money necessary been forthcoming it would in some cases have been expended in mining leads that a little knowledge of mining engineering and a little scientific examination would have shown could have yielded no adequate returns for the expenditure. Enterprise of this kind, misdirected or weakly sustained, is a questionable boon to a mining district, and the failure it brings to itself brings with it discouragement to others. In many of our new mining fields in Canada, ignorance of the principles of mining, and bad management in the initial outlay, is the fruitful source of failure, and the Lake of the Woods is no exception. The advice of trained mining engineers is sadly wanting in most mining concerns, and the importance of the profession is not recognized as it must be if we are to become the great mineral producing country we now give promise of. Another unfortunate obstacle in the way of the progress of the Lake of the Woods district has been the delay in patenting claims, necessitated by the uncertainty of jurisdiction pending the boundary award. The refusal of both Dominion and provincial authorities to grant patents for mining locations has certainly deterred several capitalists from investing their money, although assured of the success of the venture by personal examination and prospecting of the location offered for sale. This is especially true of Americans, who view with distrust any suspicion of uncertainty as to their patents. The settlement of this vexed question and the issue of patents will probably be the signal for the influx of a moderate amount of American capital, which, if expended in a business-like way, will be of the greatest service in developing the region. Gold there is; but to win it from the rocks it is essential to be able to command both money and engineering skill. The gold, though in fairly paying quantities, is rather finely disseminated, and its treatment requires careful and economical management to secure good profits, since there is not likely to be any bonanza that will render good or bad management a matter of indifference.

The Bank of England by law is obliged to purchase all gold bullion offered to it of standard fineness at 77 shillings and 9 pence per ounce, which bullion it can have coined at the mints at the rate of 77 shillings and 10½ pence per ounce.

KINGSTON RED GRANITE.

The question having incidentally arisen as to the relative durability of so-called syenite and granite under conditions of exposure and abrasion, it was thought desirable to obtain scientific opinion. The question was accordingly submitted to Mr. Willmott, a well-known scientist in high official position. The written opinion of that gentleman is contained in the following letter addressed to the president of the Canadian Granite Company:—

A. MACLEAN, Esq.,

President Canadian Granite Co., Ottawa.

DEAR SIR,—Yours of the 30th at hand, asking my opinion of the relative value of the so called Syenite now being used by the corporation of Ottawa for road macadam, and the "Canadian Granite Co.'s" granite from Kingston.

The rock called syenite is probably a hornblende gneiss (the latter mineral greatly predominating), together with a small quantity of felspar, and variable proportions of quartz. The whole impregnated more or less with iron pyrites.

The granite, which is of a medium grained texture, is composed of a dark salmon red cleavable felspar, without any apparent visible signs of decomposition. This material is cemented with a bluish white opalescent quartz in just sufficient quantity to give binding properties to the felspar, the two minerals assuming great uniformity. There are two accessory minerals, hornblende and mica—the former occurring in greenish black specks, and the latter much more sparingly in disseminated scales. In texture it is much finer grained than the Bay of Fundy, and of a more decided color.

The granite is harder than the syenite, but not so tough; this superiority of the latter, however, is sadly marred by the presence of distributed pyrites, which in some cases mark the lines of stratification. This mineral decomposes very rapidly, leaving small empty cells, and thereby increasing the absorptive power of the rock. So, altogether, taking the inferior hardness of the syenite and its likelihood of early disintegration, I cannot but think the granite altogether better calculated for road material.

We may imagine two pieces of the same size, one the syenite, the other granite. When first laid down the syenite is probably the toughest, but after the lapse of a very short time it would be found that the granite would resist a much greater strain than the syenite, through reasons before mentioned. And again, leaving the decomposing agent (pyrites) out of the question, the syenite, on account of its inferior hardness, would be reduced to its minimum in much less time than the granite.

I am, dear sir,

Yours respectfully,

CHAS. W. WILLMOTT.

Iron Mining in Ontario.

The only iron mine that has been continuously worked during the past year in the Province of Ontario, is the *Coe Hill* mine in the County of Hastings, but, on account of the low price of iron, there has been a limited shipment of ore. Up to the 6th July, when the company ceased forwarding from the mine, about 10,000 tons had been shipped and since that date upwards of 20,000 tons have accumulated in the ore heap and await shipment when the market will have improved. This mine is operated by the Ontario Central Railway Com-

pany, and the ore is shipped to Cleveland. It is one of the most promising iron mines in Canada and is rapidly developing into a heavy producer. The vein varies in width from 12 ft. to 40 ft., and has an average of quite 20 ft., as has been proved by three shafts sunk on the vein to the depths of 95 ft., 100 ft., and 130 ft. respectively.

In Tudor Township, County Hastings, work was started at the *St. Charles* mine in October, the object being merely to prove the vein and forward a shipment of ore, before the close of navigation, to be tested. The vein appears to have a width of about 30 ft., and on it a test shaft has been sunk 25 ft. in depth disclosing a fine body of magnetic ore. This mine is situated within a mile of the track of the Ontario Central Railway, and a spur has been put in which connects it directly with the main line.

CORRESPONDENCE.

MINING NEWS.

Editor of the Canadian Mining Review :

SIR,—I have been a constant reader of your paper from its commencement, and I wish to congratulate you on the steady progress which has been made by THE MINING REVIEW, until it is now recognized as a well established medium of great value to the mineral interest in the Dominion. There is one point, however, to which I would like to call the attention of your numerous readers, namely, the importance of their sending you mining news and reports of the discovery of minerals. It has often been a matter of surprise to me how you are able to obtain the large amount of news of this sort which THE REVIEW already contains. Your efforts to supply a good mining paper deserve to be more generally seconded by all mining men, and in fact by everyone interested in any way in the development of the mineral resources of our common country. Hereafter I shall send you any items of information of this kind which come in my way, and if other miners in all parts of the Dominion would do the same we could make THE REVIEW more valuable to each other, and create a more general interest in a real live mining paper. It is impossible for the editor of a journal devoted to a special subject, no matter how gifted he may be, to know everything which may be going on over the length and breadth of half a continent. I am sure that all miners and mine owners in the country wish you success in an enterprise so well calculated to benefit themselves, but the trouble is that there are not enough of them who have been willing, heretofore, to sit down and write you from time to time what they know would be of interest to your readers, and which they would be quite willing to tell if asked verbally. The information I refer to might often be the means of leading to a sale and the development of valuable properties, which would otherwise never be heard of by those desirous of investing in them. Although most of us are more accustomed to handle the pick than the pen, still I have no doubt, Mr. Editor, that you would value even rough or hurried notes on new discoveries, or on the condition or progress of any mine or mineral property that may be working, and that you would put such notes into shape for the press, or see that the printers' proofs were carefully revised. I trust, therefore, that many other miners will join in helping along THE REVIEW in the way I have indicated.

OLD MINER.

[Since the first number of THE REVIEW was issued, our experience has been such as to lead

us to endorse the sentiments expressed by our correspondent, and we feel ourselves indebted to him for his practical suggestions. Canadian mining news and reports of new discoveries of mineral deposits cannot reach those interested in such matters through a better or a more direct channel than by appearing in the columns of this journal. It is always available for the publication of reliable information, and it would be gratifying to us if our readers will be guided by the hints thrown out by "Old Miner" and use THE REVIEW more generally for distributing news and reports affecting the mineral resources of the Dominion.—ED.]

Canada Consolidated Gold Mine.

This property has been worked for some years but, as yet, unsuccessfully, and from the reports which have reached us from time to time we are forced to believe that the cause for this is not due to poor ore or to the size of the veins that have been opened, and must be looked for in the management or in the manner in which the ore has been treated. The mine is situated in the Township of Marmora, Hastings County, Ontario, and within a short distance of the village of Deloro. Three shafts have been sunk on a vein, varying in width from 5 to 15 ft. and averaging about 7 ft., and some drifting and stoping has been done on the vein. The deepest of these shafts is now at a depth of 135 ft. and drifting and stoping has been done at the 60 ft. level. Another shaft known as the *Tuttle*, is down 60 ft. on the vein, from which level they have been drifting and stoping with a view to meet the 60 ft. level of the deep shaft, and from this portion of the vein the richest ore has been obtained. The workings from these two shafts are now about 180 ft. apart, and between them (the *Tuttle* and deep shaft) another shaft is being sunk to catch the common 60 ft. level, but we are not informed for what purpose this third shaft is being put down. The ore of this vein is a mispickel, rich in arsenic and carrying about \$15 in gold, per ton. If there is no fault to be attached to the management at this mine, and if the ore is properly treated, it is difficult to find a tangible reason why a vein averaging nearly seven feet in width and carrying quite \$15 to the ton in gold, as well as a large quantity of arsenic, cannot be worked at a handsome profit. These are the conditions at the Canada Consolidated Gold Mine in Hastings County; a seven feet vein yielding \$15 per ton in gold and rich in arsenic, and yet it has been, up to the present time, a losing enterprise. We will be pleased to any one who will account to us for this state of things.

MANUFACTURE OF IRON IN CANADA.

At the meeting of the American Institute of Mining Engineers at Halifax, in September last, a paper was read by Mr. J. H. Bartlett, of Montreal, giving a complete resumé of the attempts which have been made to manufacture iron in the various provinces of the Dominion since the year 1737 to the present time. Mr. Bartlett has compiled his paper from reports of recognized authorities on the subject, who have, from time to time, been employed to investigate the iron industries, and from facts obtained from the records of the various organizations which have been engaged in the manufacture of iron in Canada during the past century and a-half. Mr. Bartlett's paper presents the facts as he has found them, after much

research, to exist, and, without offering any comment, leaves us to draw our own conclusions. The information that he has put into our hands is such as to lead an enquiring mind to look for the cause of the repeated failures he has thus placed on record, and he leaves us to find out for ourselves why, in almost every instance, disappointment should have attended the efforts of our iron manufacturers rather than a realization of the success promised them by promoters. It is evident that Mr. Bartlett's intention has been to open up a broad field for discussion, and for our own part we congratulate him on his success in so doing. In almost all instances in Canada, of which we are informed, where attempts have been made to manufacture iron profitably, and have proved abortive, the cause of failure can be traced to bad management, ignorance, and systematic disregard of economy, together with too limited capital, and, in many instances, unlimited capital could not have overcome the disastrous effect of the shortcomings of promoters and managers—perhaps mismanagers might be more appropriate. Mr. Bartlett's paper has disclosed unpleasant and uncontrovertible facts, and in the absence of an intelligent explanation of their existence the industry of iron manufacturing in Canada will not, henceforth, hold out much inducement for the investment of capital. It now behoves those who are interested in the development of our iron ore deposits to account for the cause of failure in the past, and to point out a place whereby iron can be successfully and profitably produced.

It will be impossible for us to publish Mr. Bartlett's paper *in extenso*, and we, therefore, content ourselves with printing the following review of it which has appeared in the *Cleveland, Ohio, Iron Trade Review* :—

"The history of iron manufacture in Canada appears to have been written in failures. Reading with much interest the 35 pages of a paper read before the recent Halifax meeting of the American Institute of Mining Engineers, by James Herbert Bartlett, of Montreal, on 'The Manufacture of Iron in Canada' we have been struck with the almost uniform disaster which has attended the efforts of enterprising capitalists to utilize the mineral resources of the Dominion. The discovery of iron ore in the St. Maurice district of the Province of Quebec dates back to 1667, when the West Indian Company had a practical monopoly of all mines and minerals in that vast region. It was not until 1737, however, that, after numerous vicissitudes, any practical effort was made to utilize the mineral wealth displayed. In that year 'La Compagnie des Forges,' being duly chartered by Louis XV., of France, erected a blast furnace. Want of capital, however, caused a suspension of the works, and the Crown took possession of and operated them. The iron was sold at the rate of from 25 to 30 castors (beaver skins) per hundred-weight. Quantities of it were also exported to France. The works finally passed into the hands of private parties by lease, and by 1810 the manufacture of iron was the most important industry in Canada, there existing then a considerable export of cast-iron articles, particularly of stoves. From one set of men to another the works descended until they passed into the hands of the present owner, Mr. George McDougall, of Three Rivers, the furnace having been in blast till the summer of 1883, when, owing to the ore and fuel becoming exhausted, it was finally closed. When working it was the oldest active blast furnace on the American Continent. Toward the last its business had steadily fallen off until there was no profit in it.

We have cited this particular instance, first, because it was the pioneer iron-making enter-

prise of Canada, and secondly, because it is but a type of nearly all the concerns which have followed it. The Radnor forges, at Fermont, established in 1860, sunk over a million dollars through bad management and were finally destroyed by fire. L'Islet Blast Furnace, near St. Maurice, has not been in operation for years. The Canada Iron Mining and Manufacturing Company's blast furnace, at Hull, was started in 1857 and soon after abandoned as a failure, economically. The St. Francis River Mining Company's furnace, in the County of Yamaska, built in 1869, was abandoned in 1880 on account of the exhaustion of the ore supply. The same may be said of the works at Baie St. Paul, Moisie, Quebec, Haycock, and Montreal (abandoned after \$80,000 had been spent in experimenting with crude petroleum as fuel). The only successful works in the Province of Quebec are the Grantham Iron Works, in the County of Drummond, and four concerns in Montreal.

Turning to Ontario, we find the history of her sister Province repeated in nearly every instance. The first attempt to manufacture iron in Ontario was made at Lyndhurst, County of Leeds, in 1800, water being utilized to drive the machinery and work the blast. Only ruins remain to tell the story of the ultimate financial disaster. Normandale Furnace, in the County of Norfolk, built in 1815, made a few tons of iron and then became "bunged up" and sent the disheartened projector to his grave. Subsequently it enjoyed a term of high prosperity but was ultimately abandoned on account of the failure of the supply of raw materials. Another "big hole" into which English, Canadian and American capital was successively "blown" was the Marmora Iron Works, once successful, but now in ruins. The Madoc Blast Furnace, built in 1835, had a short run and finally ran into the ground. So, also, with the Houghton Iron Works, the Furnace Falls Iron Company (1882), the Toronto Rolling Mills and Iron Works (1860-1873), the Steel, Iron and Railway Works Company, of Toronto (1866-1873), Date's Patent Steel Company, Toronto (1873), and the London Steel Works (1883-4)—all tell the same wearisome and disheartening story. The only iron works now running in Ontario are the Hamilton Iron Froging Company and the Hamilton Rolling Mill.

In New Brunswick only one attempt has been made to erect smelting works, namely, at Woodstock in 1835, which, however, were closed down in 1862. Three rolling and forging mills are now running—one at Coldbrook and two at Portland.

In the discovery of iron ore Nova Scotia precedes all other provinces, first mention of the same having been made in 1604. The first attempt to manufacture iron was not made, however, until the beginning of the present century. Passing over several minor projects (which, it seems needless to remark, resulted disastrously), we refer briefly to the celebrated Acadia Iron Works, at Londonderry, only to say that, after a remarkable history of ups and downs for 35 years, during which millions of dollars have been sunk, they are now in liquidation. There are at present in operation fairly successful forge and plate works at Halifax and Trenton.

Subsequent to the publication of the foregoing, Mr. T. D. Ledyard, of Toronto, addressed a letter to the Editor of the *Iron Trade Review*, which has since appeared in the columns of that journal, as follows:—

"I noticed an article in a recent number of the *Review* giving a doleful account of failures of iron works in Canada. It is only too true that many of these enterprises have been unfortunate, generally, however, through bad management. There was great extravagance in connection with the Marmora Iron Works and the iron was teamed about 30

miles to Belleville at great expense. John McDougall, of the Caledonia Iron Works, Montreal, and McDougall Bros., of Three Rivers, in Quebec, have been successful for a number of years in smelting iron, mostly from bog ore. It is difficult to see why a furnace in connection with such an ore property as described in the enclosed report should not be successful. There is plenty of excellent ore, well situated, with fuel and flux close at hand." Yours truly, T. D. LEDYARD.

If our view of the manufacture of iron in Canada was a trifle doleful, our correspondent will have to settle that with the writer of the paper read before the Halifax meeting of the American Institute of Mining Engineers, whose main points were condensed into our article.

The deposit referred to by Mr. Ledyard is in the township of Belmont, Peterborough, Ontario, six miles west of the Central Ontario Railway and within four miles of connection with the Ontario & Quebec Railway. Selected specimens of the ore have analyzed as high as 64.26 per cent. of metallic iron, as low as 0.04 per cent. of sulphur, a faint trace of phosphorus and no titanium. Explorations appear to show that the deposit is of wide extent. The ore is strongly magnetic and of fine grain. Professor Hayes, of Toronto, says of the advantages which this district affords for the smelting of ore:

"The facilities for obtaining hard wood and charcoal from the surrounding country are especially favorable, from the close proximity of Belmont Lake and its tributary waters, including Crow River, which flows through Lots 14 and 15 of the same range, within a mile and a half of the mine. A fine site for erecting a blast furnace is found on Crow River close to the branch railway line, on which there is also powerful and never failing water power. Abundance of limestone for flux is found on these waters."

It is estimated that the ore can be laid down at the furnace for \$1.25 per ton. The Canadian Government gives a bonus of \$1.50 per ton on all iron and steel manufactured in Canada. With such apparently favorable conditions as these, the question would naturally arise, Why has not capital long since taken hold of an enterprise so promising?

We would urge others to take up the subject as Mr. Ledyard has done and to point out the advantages of iron smelting in Canada, in contradistinction to the unhappy experience of the past, as pointed out to us by Mr. Bartlett.—(Ed.)

ORIGIN OF THE NATIVE IRON OF GREENLAND.

Since 1813, pieces of native iron have been brought from Greenland by many explorers, and have, in nearly every case, been ascribed to meteoric origin. Steenstrup, in his third voyage to Greenland (1876-1880), however, found the iron native in a basaltic rock at Asuk, in grains varying from a fraction of a millimeter to eighteen millimeters. It is also found on the western and northern sides of Disko Island, and in other places. This settles beyond a doubt the question of the origin of the Greenland native iron, and the ore may be of great commercial importance in the future.

IMPROVEMENT IN THE BESSEMER PROCESS.

An improvement has been made on the Bessemer steel process at the Edgar Thompson Steel Works which, it is said, will have the effect of making Bessemer steel equal in quality to crucible steel, while it will cost only about one-tenth of the price. The change consists in a thorough mixing of Spiegel iron or manganese with molten iron in a ladle, so as to uniformly carbonize it. Bessemer steel can be produced at a cost of a cent to a cent and a half per pound, while that made in crucibles costs at least eleven cents per pound.

It is in contemplation to erect a large asbestos manufacturing mill at Thetford, Beauce.

MINERAL WOOL.

In the last issue of the *REVIEW* we referred briefly to this material and the various uses to which it can be applied to advantage. It is also known by the name of *silicate cotton*, and is useful for the insulation of heat, as a protection against frost, for a preventive of the spreading of fire, for deadening sound, and as a safeguard against the ravages of rats, mice and insects. *Mineral wool* is the slag of blast furnaces converted into a fibrous state. The process consists in subjecting a small stream of the molten slag to the impelling force of a jet of steam or compressed air, which divides it into innumerable small shot or spherules, forming a spray of spark-like objects. The threads are spun out immediately upon the detachment of the slag particles from the main body of the stream, their length and fineness being dependent upon the fluidity and composition of the material under treatment. When the slag is of the proper consistency, the shot are small at the outset, and are to some extent absorbed into the fibre; but in no case will they entirely disappear, so that it becomes necessary either to separate the two while still in mid air, by strong currents, or else to put the bulk of the product through a riddling machine. The finer and lighter threads are carried away from the shot, and heavier fibres, making a gradual separation between the extreme fine and the coarse. The production is divided into two grades; the *ordinary* includes all the *mineral wool* weighing over fourteen and less than twenty-four pounds, and the *extra* includes what weighs less than fourteen pounds to the cubic foot.

The resemblance of the fibres to those of wool and cotton has given the names by which the material is known, *mineral wool* and *silicate cotton*, but the similarity in looks is as far as the comparison can be followed. The hollow and jointed structure of the organic fibre, which gives it flexibility and capillary properties, is wanting in the mineral fibre. The latter is simply finely spun glass of irregular thickness without elasticity or any such appendages as spicules, which would be necessary for weaving purposes. The rough surfaces and markings of the fibre can only be detected under a strong magnifying glass.

The drawing out of the fibres is a mechanical operation; it is a remarkable illustration of the wide variety mineral substances will assume under different conditions of cooling. Fleecy *mineral wool* is, in reality, identical in composition with the hideous blast furnace slag.

The peculiar reason why *mineral wool* is a non-conductor of heat is owing to the quantity of air it contains. Air is subtle and rapid in its movement, and is so slow to convey heat, except on its own motion, that it becomes a distributor of it, and also a barrier to its transmission, according as it has, or has not, freedom to circulate. If the air-confining material is not very loose and porous it will be found to transmit heat, and the reduction of the percentage of volume of air, by making the material more compact, develops its capacity for conducting heat.

One cubic foot of slag weighs 192 pounds, while the same weight in ordinary *mineral wool* measures eight cubic feet, so that the resulting fibres encase eight times the quantity of air that the slag did; in other words, the cubic foot before conversion contained 100 per cent. of material, and after conversion only 12 per cent., therefore the product must contain 88 per cent. of its volume of air. The *extra* grade has 92 per cent. of its volume of air, and is, conse-

quently, a better non-conductor than the ordinary.

The transmission of sound is prevented by a filling of *mineral wool*, because of its elasticity and want of solidity. It therefore possesses the properties of heat-proofing, fire-proofing and sound-proofing, and is also valuable on account of the irritation which the glass fibres cause to insects and vermin, and the fact of there being nothing in its composition to help to breed or harbor insects.

One objection that has been raised to the use of *mineral wool*, made from furnace slag, is that it will corrode pipes or boilers whenever leaks occur or exterior dampness penetrates it. Water is, of course, the primary cause of the rusting, but it is claimed that the percentage of sulphur contained in the slag becomes dissolved by the water, and in the form of sulphuric acid attacks the surfaces unless they are kept dry by radiated heat. In order to obviate this fault, where it would be objectionable, an article is now being manufactured from non-sulphur bearing rocks which is absolutely free from sulphur and its compounds. It is distinguished by the name of *rock wool*, and though more costly than the *slag wool*, the difference in weight reduces the cost of transportation in favour of the former article.

It is admitted that *silicate cotton* stands at the head of the list as an insulator, 10 inches thick, being equivalent to 12 to 15 inches of wood charcoal; but it is very much more costly, and it is claimed by some that it possesses the fault of being friable and liable to fall into powder, especially if used on board ship, from the incessant motion of the vessel when out at sea. This objection has been controverted from the fact that it is the practice of the Chicago, Milwaukee and St. Paul Railway Company to jacket their locomotive boilers with *extra mineral wool*, and that since 1878 the passenger cars of the Pennsylvania Railway Company have been lined with *ordinary* quality. The vibrations in both cases must be severe, and its adaptability for these purposes has been established.

The Krupp Iron Works at Chemnitz.

The American Consul at Chemnitz, Mr. George C. Tanner, reports, under date of September 1, 1885, the following interesting particulars concerning the Krupp works at that place:

The Krupp Iron Works, which were founded in 1810, employed in 1855, 693 workmen.

The number of workmen in 1882 was 10,598; the number of houses they occupied was 3,208, in which, including families, 16,200 people lived. These houses were built in flats containing from two to five rooms, the rent of which ranged from \$16 to \$50 a year. A boarding house was also established by the managers of the Krupp Works which would accommodate 500 men, where dinner with meat four times a week, coffee, butter, and everything is provided but bread. A co-operative store exists and has proven very beneficial to the operatives of Mr. Krupp. A sick club has existed since 1856 and in 1882 had 11,011 members and a fund on hand of \$313,490.

The pensions in 1882 amounted to \$10,042, and the death liabilities to \$1,000. There is a sanitary committee at the works. The works have had a fever hospital since 1871 and an infirmary since 1872. A disinfection house and appurtenances have also been instituted on Dittmar's plan. Baths are placed near the entrance of the works for the use of the working people.

In 1876 a life insurance fund was started and is now in a flourishing condition. A high school

with twenty class-rooms, and a private school with sixteen rooms are among this gentleman's beneficent care, and since 1876 five technical schools have been in existence in which, among other instructions, women are taught household work or the art of making home comfortable on a minimum of expenditure. Charities for disabled men, women and invalids generally, have been in operation for more than ten years where those not utterly disabled may prosecute light work, such as brooms, baskets, shoes and other labour of the kind which goes to the co-operative stores. In one week of last year the number of labourers dependent upon and who received the benefits of Mr. Krupp's humane treatment was 65,381.—*E. and M. Journal*, N.Y.

SPRING HILL COLLIERIES, NOVA SCOTIA.

One of the results of the Halifax meeting of the American Institute of Mining Engineers, held in September last, has been to bring prominently before the American people the importance of the mineral resources of Nova Scotia—notably, her coal fields and iron ore deposits. The most important development in the coal fields of the province has been at the Spring Hill collieries, of which the *Engineering and Mining Journal*, in an article on the subject, says—"The Cumberland coal basin, Cumberland County, Nova Scotia, is the most easterly coal field in the province, and it is also one of the most important in area and in thickness of coal. The limits of the Cumberland coal field are not definitely known, but little exploration work having been done; but it is estimated by Mr. Edwin Gilpin, inspector of mines, to cover 300 square miles out of some 685 square miles of known productive coal area in the province.

By far the most important development in the Cumberland field is at the Spring Hill collieries, where extensive mining operations have been carried on during the past ten years by the Cumberland Coal and Iron Company, which owns some 20 square miles in this field. These operations have proved this basin to contain the following seams and intermediate measures:

Coal, North seam worked	13 feet.	
Strata		105 feet
Coal seam	5 "	
Strata		130 "
Coal seam	2 " 4 in.	
Strata		185 "
Coal, Main seam worked	11 "	
Strata		80 "
Coal, South seam, worked	11 "	
Strata		180 "
Coal, opened	8 " 6 in.	
Strata		190 "
Coal	4 "	
Strata		176 "
Coal	2 " 9 in.	
	57 ft. 7 in.	966 ft.

Other workable seams are known to exist below these.

Three of these seams are extensively worked and have produced in the past eight years the following quantity of coal:

1878	100,621 tons.	1882	210,000 tons.
1879	88,405 "	1883	200,000 "
1880	127,297 "	1884	250,000 "
1881	160,485 "	1885 (estimated)	300,000 "

The extent of the workings shows clearly both the regularity of the coal-seams and the quality of the coal. With regard to the former, it may be said that the beds are remarkably uniform in thickness and quality, with neither faults nor pinches, and but very little shale in the seams. The inclination of the beds varies from about 38 degrees at the south end of the field (where the measures are cut off abruptly by a fault that cuts across the line of strike), to 14 degrees at the north slope on the south seam,

nearly four miles on the outcrop distant from the fault. The mines are opened by four slopes of various depths up to 1,300 feet, and levels have been driven out for a length of more than two miles.

THE QUALITY OF THE COAL.

The coal is a good steam and coking coal, as the following analyses, made by Mr. Edwin Gilpin, Jr., testify:

	North seam.	Main seam.	South seam.	6-foot seam.
Moisture	1.625	.78	1.39	3.47
Vol. combustible	28.672	31.32	31.22	26.98
Fixed carbon	65.431	62.54	61.58	64.48
Ash	4.272	5.34	5.79	5.07
	100.000	99.98	99.93	100.00
Sulphur	.781	1.38	.80	.23
Theoretical evaporative power	8.099		8.46	8.86

In ordinary shipments in quantity no doubt the amount of ash, and with it the percentage of sulphur, would exceed the figures here given; but it is nevertheless true that this property produces a fuel of excellent quality for general manufacturing purposes, and even unwashed slack yields a fair furnace fuel; while, if the slack were washed and coked in, say, a Simon-Carvès oven, it should produce an excellent coke at a very moderate cost. The great thickness and regularity of the beds, their freedom from slate bands; the soundness of the roof and floor, which neither fall nor creep; the comparative dryness of the mines and their total freedom from fire-damp—which has never been met with, though the mine has a depth of 1,300 feet on the seam—are all conditions which promote economical production, and should, with a large and easily accessible market, make this property not only extremely valuable to its proprietors, but a very important and interesting source of supply for our American consumers, manufacturers and furnace men to consider.

The Spring Hill collieries are connected by 27 miles of railroad—owned by the colliery company—with the fine shipping port of Parrsboro' on the Bay of Fundy. By a proposed extension of about one mile the docks can be placed where there will be open navigation the year through, with the exception of a few weeks in winter. On the other side, these collieries connect with the Intercolonial railroad, and it is proposed to add a short line of railroad to the port of Pugwash, on the waters of the St. Lawrence.

So far as the colonial markets are concerned, the Spring Hill collieries supply the Dominion Government, principally for the Intercolonial railroad; the Richelieu & Ontario Navigation Company; the Grand Trunk railroad; Montreal, and other roads and cities. A small quantity of the slack only comes to the American market, though freights to New York harbor from Parrsboro', it is said, could be made at \$1 to \$1.25 a ton, for large and regular shipments.

American industries have an especial interest in this great coal-field, for it may become a very important source of supply for manufacturing and metallurgical works situated along our Eastern seaboard. Considering the fact that we export to Canada far more coal than we import from all countries, there is a fair probability of reciprocity in coal, at least, being enacted in the interest of our coal and manufacturing industries.

We imported only 64,515 tons of Nova Scotia coal last year; while we exported, almost exclusively to Canada, in the same year, 1,342,018 tons of anthracite and bituminous coal. In Canada our coal pays a duty of 60 cents a ton; while Nova Scotia coal coming into this country pays a duty of 75 cents a ton for all except slack, which pays 30 cents a ton. No doubt the

removal of the duty on both sides would increase our exports far more than our imports of coal and it would afford a cheaper fuel to our metallurgical works situated on the Atlantic coast.

At what price could we then obtain coke in New York harbor? Spring Hill slack could probably be delivered f.o.b. at New York, with a fair profit to the mines, at \$1.75 a ton, and run of mine at perhaps \$2 to \$2.25. And as the by-products of coking in the vicinity of New York could be utilized, and would return a profit on the operation, the cost of coking need not be counted. A good furnace coke could therefore be delivered here at from \$3.50 to \$4 a ton, which is about the present price of furnace coke here, while to work at Boston and farther east the cost would be still less.

Experience has demonstrated that with the present duty no considerable amount of Nova Scotia coal can come in while our superior Cumberland and Clearfield coals are sold at the mines, including miners' profit at 7½ cents a ton and are carried by our railroads at three mills per ton-mile; but the time will come, whether through reciprocity in a few raw materials, or, later on and better yet, by annexation of the New Dominion, when the vast mineral resources of Nova Scotia will be developed by opening to them an enormous market in our Eastern States. Then will the great Spring Hill collieries, which, now in their infancy, have a capacity of from 1,200 to 1,500 tons a day, grow into the realization of the magnificent, though by no means visionary, plans of their very able and enterprising managing director, Mr. R. G. Leckie.

COAL IN CHILI.

The only sources from which fuel can be obtained in all South America are, it is said, the coal mines that lie at the extreme southern limit of the populated district of Chili. Taichuan is the nearest port of importance; but the towns at the mines are Lota and Coronel. The mines are entered by shafts that are immediately over the water of Lota Bay, so that the coal is drawn on trucks to the mouth of the mines, and dumped into launches and lighters, which are towed out to the anchorage of ships. It is said that it costs \$1.35 a ton to mine and deliver this coal on ship-board, and that the owner, Donna Isadora Cousino, of Santiago, who is said to be the Ceresus of South America, will not sell at less than \$7.50 a ton, just a shade less than the cost of imported Cardiff coal.

COST OF PRODUCING CHARCOAL.

In the manufacture of charcoal iron, one of the most important points to be considered is the cost at which charcoal can be produced in the vicinity of the furnaces, and for the benefit of those who may be seeking such information we publish the following extracts from an article on this subject which has appeared in the *Journal of the United States Association of Charcoal Iron-Workers*.

"In the manufacture of charcoal, one of the prominent factors of cost is the value of the wood used, and we have found instances in which parties seem to misunderstand or fail to appreciate the bearing that a few cents per cord, added to the price of cord-wood, has upon the cost of a bushel of charcoal made from it. This want of appreciation we find the more marked where the smaller yields of charcoal are obtained, and where, as a consequence, the proportion of the cost of wood per bushel is greater than where a larger number of bushels of char-

coal is obtained from a cord of wood. For the purpose of showing the importance of attention to this subject, we have prepared the following table, which illustrates the value of using the process or processes of carbonization that gives the largest yield in bushels per cord, particularly where the cost of chopping wood or the value of standing timber is great.

"We have known wood to be cut for 30 cents a cord, and have been informed that in exceptional cases over \$1 a cord has been allowed choppers.

"Where kilns or retorts are used, cord-wood is often purchased, delivered on the railroad or hauled to the plant; and for such delivery some charcoal iron-works pay from \$3 to \$4 a cord. We have, therefore, shown the cost of wood as ranging from \$1 to \$4 a cord for wood purchased, cut, and delivered; the prices advancing from 5 cents up to \$2 a cord, and from that figure advancing by 10 cents to \$4 a cord.

"In coppice growth, or where inefficient colliers are employed, or where the cord of wood purchased is not a full cord, a yield in meilers as low as 20 bushels of charcoal from a cord of wood has been obtained, and where liberal cord measure is obtained, it is claimed that 75 bushels of charcoal a cord can be secured by the judicious operation of retorts, and we have

VALUE OF WOOD IN 100 BUSHELS OF CHARCOAL.

Price of Wood, Stumpage, Chopping, or Delivered at Works.	Yield of Charcoal in Bushels obtained from one Cord of Wood.						
	40	45	50	55	60	65	75

3.20	8.00	7.11	6.40	5.82	5.33	4.92	4.57
3.30	8.25	7.33	6.60	6.00	5.50	5.08	4.71
3.40	8.50	7.56	6.80	6.18	5.67	5.23	4.86
3.50	8.75	7.78	7.00	6.36	5.83	5.38	5.00
3.60	9.00	8.00	7.20	6.55	6.00	5.54	5.14
3.70	9.25	8.22	7.40	6.73	6.17	5.69	5.29
3.80	9.50	8.44	7.60	6.91	6.33	5.85	5.43
3.90	9.75	8.67	7.80	7.09	6.50	6.00	5.57
4.00	10.00	8.89	8.00	7.27	6.67	6.15	5.71

therefore embraced in the table a yield covering every possibility, and varying from 20 bushels to 80 bushels. The figures advance by fives, and from these and the cost of wood any intermediate amounts can be approximated.

The cost of wood per 100 bushels of charcoal is given to obviate using fractional parts of a cent for single bushels, and it has not been deemed necessary to carry the calculations beyond where the wood would cost less than one tenth of a cent a bushel, nor more than 10 cents a bushel of charcoal."

The table published in the *Journal of the United States Charcoal Association of Iron-Workers* runs from 5 cents to \$4 a cord for wood, and from 20 to 80 bushels yield, but we have only printed those figures which will apply to localities in

Canada where it is at all likely that the manufacture of charcoal iron may be engaged in.

"We have been furnished with a detailed estimate of the actual cost of meiler coaling in a tract of large timber yielding 60 cords an acre in Tennessee, the cost being taken from absolute expenditures.

COST OF MAKING 100 BUSHELS (2258 CUBIC INCHES EACH) OF CHARCOAL.

Making hearth and preparing dust for cover	\$0.220
Hauling wood, leaves, and water to hearth	.750
Drawing charcoal from cover	.375
Setting and covering wood	.375
Tools	.050
Hire of cattle and feed	.085
Wages of boss collier and incidental expenses	.200

Total \$2.055

Or a little over 2 $\frac{1}{10}$ cents a bushel of 2748 cubic inches.

"Coaling sapling wood costs from 2 $\frac{1}{4}$ to 3 $\frac{1}{2}$ cents a bushel.

"To this add cost of cutting and ranking wood, value of wood-leave, and hauling charcoal to works."

Plymouth Consolidated Gold Mine.

The result of the operations at this mine for the nine months ending 30th September, 1885, show that work has been carried on during that period at a profit of nearly two hundred per cent., which is made the more remarkable by the fact that this enormous profit has been realized from ore that did not yield \$13 per ton in gold, average. The monthly production, expenditure and disposition of profits, have been as follows:

QUARTERLY REPORT, OCTOBER 1ST, 1885.

Gold Bullion produced January, 1885	\$85,721 99
February	80,974 87
March	80,135 03
April	82,191 67
May	81,927 39
June	82,656 70
July	82,240 83
August	73,156 97
September	75,644 98
Total product for nine months, 1885	\$724,650 43
Operating Expenses—January, 1885	\$25,761 45
February	26,721 11
March	29,448 34
April	27,152 62
May	24,909 32
June	25,704 61
July	29,686 29
August	29,831 95
September	26,910 17
Total Operating Expenses, nine months, 1885	\$246,105 86

Profit	\$478,544 57
Cash on hand, January 1st, 1885	74,295 06

Amount applicable to dividends	\$552,839 63
Paid nine monthly dividends (Nos. 20 to 28, inclusive) of \$50,000 each	\$450,000 00
Construction Account, nine months	15,833 79
	\$465,833 79

Cash surplus, Oct. 1st, 1885 \$ 86,985 84
The cash on hand, \$86,985.84, is "actual surplus," the Company having no indebtedness whatever.

In his quarterly report the president states that the year has been an unusually dry one. The rainfall of last winter and spring was extremely light, and the season commenced with but little snow in the mountains. A summer of excessive heat followed, causing large loss of water by evaporation. The supply of water for power had thus been curtailed and rendered it necessary for several weeks to run one of the mills on short time. On this account the product for August and September were below the average, and the same cause will have reduced the output for October. By November it was expected the fall rains would have commenced, and it is unlikely that the drawback of the past season will be repeated for many years to come.

Since 1880, when diggings for amber commenced under the Smaland Peninsula in East Prussia, the yield of the veins here has greatly increased. In 1864, the revenue was \$8,500, against \$125,000 in 1883.

South African Diamond Trade.

Returns recently published in Kimberley give the production of Cape diamonds from the four chief mines during the three years ended Aug. 31st last, as follows:—

	Carrats.	Value.
Kimberley.....	2,280,123	£2,211,239
De Beer's.....	1,447,335	1,516,353
De Toit's Pan.....	1,483,184	1,099,666
Bultfontein.....	1,615,878	1,658,070
Total.....	6,826,520	£7,485,338

Dividing the three years into two periods of eighteen months each, it appears that the production of the Kimberley mine fell off one half during the second period, while the other three mines increased their output one-sixth. The exports in each year are as follows:—

	Carrats.	Declared value.
Four mos. ended Dec. 31, 1882.....	796,546	£1,156,273
In 1883, 12 months.....	2,413,954	2,742,521
In 1884, 12 months.....	2,263,636	2,877,288
In 1885, 8 mos. ended Aug. 31.....	1,537,196	1,586,795
Total 36 months.....	7,011,382	£8,292,878

It thus appears the exports of diamonds from the colony (making allowance for exports not included in the returns) can not have been worth less than £9,000,000 for the three years, or an average of £3,000,000 a year. Were this sum struck out from the total export trade, the balance against the colony would obviously be very serious. The importance of suppressing the trade in diamonds stolen from the mines, to which the Cape Government has latterly given increased attention, is thus apparent.

MINING NOTES.

NOVA SCOTIA.

A bar of gold was taken to Halifax on December 1st from the Archibald & Mott mine, at Salmon River. It weighed 900 ounces and was valued at \$17,000.

The gold mining property near Oxford is now under the management of S. J. Keyes & Co., and report says it is likely to prove as rich as the well known Oxford mine.

It is reported that a party engaged in prospecting in Lunenburg county has discovered several rich lodes, and it is expected that next spring will see a boom at the Lunenburg gold mines.

The reputation of the Salmon River and Albion mines will, in the opinion of an expert, be equalled by that of the Crow's Nest mine in Gysboro, the indications being that the latter mine will become an important gold producer.

Mr. Van Slooten is reported to have said that he has succeeded in raising \$1,000,000 of capital in England and the United States for investment in Cape Breton mines, provided the concessions asked for last winter from the local legislature are granted.

The discovery of auriferous deposits in the vicinity of Pleasant River, Queen's county, has caused some excitement in the district. The county has, in consequence, been visited by numerous gold prospectors, some of whom have been successful in their searches.

Work was resumed at the Coxheath copper mine in the beginning of December. About twenty hands were then employed and it was the intention to increase the force when work was well under way. This mine will be operated extensively by the Eastern Development Company, the present owners.

QUEBEC

The asbestos mines in the townships of Thetford, Colrairie and Broughton suspended operations at the end of November, and work will not be resumed until spring.

The Villeneuve mica mine continues to yield abundantly, and the output is of the same high grade as that which was shipped last autumn and established the reputation of the mine.

Since the death of Mr. Roberts, work has not been resumed at the Bristol iron mine in Pontiac county. Mr. Roberts was president of the company owning the property and it had his personal attention.

Work was suspended at all the phosphate mines in the du Lièvre district between the 24th of December and the 4th of January. The full force has resumed work and phosphate is coming to the surface as rapidly as ever.

The phosphate location, Lots 7 and 8 in the 7th Range of the Township of Bowman, has changed hands. The present owners have a force of miners at work developing the property and are confident that it will prove a rich and productive mine.

ONTARIO.

The *Cox Hill*, in the county of Hastings, is the only iron mine that was worked continuously in the province during the past year, and from it 30,000 tons of ore were raised, of which 10,000 tons were shipped to the United States.

Thunder Bay District.

It is reported that a mill for the reduction of silver ores will be erected at an early date at the *Rabbit Mountain* mine. There are now five working mines in the district.

The owners of the *Rabbit Mountain* have concluded arrangements to work their own mine and the adjoining property, known as 40 T., on an extensive scale.

A mill test, by Ballbach & Sons, Newark, N.J., of 2,785 pounds of pure ore from the east end of Silver Mountain, gave 1,039½ ounces of silver, which is highly satisfactory to the owners.

It is stated that the result of operations at the west end of Silver Mountain exceeds the most sanguine expectations, and that another rich outcropping has been discovered about one hundred feet to the west of No. 2 tunnel.

The new shaft at the Huronian mine is being rapidly sunk on the new vein, and the bottom of the shaft is in very rich ore. This vein has proved rich from the surface, and continues to improve. Work at the mine is progressing favorably, though but a small force is employed.

A new company, on the 16th December, completed the purchase of a part interest in the *Beaver*, *Silver Creek* and another mine. The force of miners at all three mines has been increased, and it is the intention of the company to put up a mill and reduction works in connection with these mines.

BRITISH COLUMBIA.

The discoverer of Granite Creek has discovered another creek which he calls the *Eagle*, and states that he thinks it will prove a much richer creek than *Granite*. Samples from rich quartz ledges have been sent down for assay.

On the Stewart river, 60 miles from its mouth, it is stated that the miners are taking out \$30 per day, per man, with rockers.

A large number of miners have gone into Scotch Creek where the diggings are reported to be very rich. The creek is easy of access, the steamer running direct to its mouth.

Nearly all the claims on Granite Creek shut down for the season about the end of November. A few miners continued to work as the weather was favourable. There are about 600 miners on the creek.

Parties arrived from Victoria in December from Granite creek had been to Eagle creek and Hine's gulch and report considerable excitement at the mines on account of the new strike, and that a large number of miners had proceeded to Eagle Creek and taken up claims.

An immense quartz deposit has been discovered on the Yukon river, which yields, according to rough assays, \$10 per ton. The facilities for crushing are ample, there being good water power and other necessities for milling the ore near at hand.

UNITED STATES.

A great mass of asbestos in North Georgia has been fully opened, and the product sells at \$40 to \$60 a ton.

In Colfax county, New Mexico, rich prospects have been discovered which, it is predicted, will prove an inviting field for a large number of mining companies.

The Gemaine Consolidated Co., Colorado, has struck a very fine crevice on the fourth level of the Bates-Hunter mine. The vein is twelve feet between the walls.

The output of Leadville mines, it is expected, will have reached \$12,000,000 for 1885. The place has about 100 producing mines, producing about 1,000 tons per day of the value of \$40,000.

It is reported that Mexican prospectors have discovered a rich gold ledge about fifteen miles south of Independence, California, specimens from which have assayed \$150 to \$200 in gold, per ton, besides a fair percentage in silver.

Notwithstanding the comparatively low price of copper, there has been an appreciation in the price of the shares of the Calumet and Hecla and seven other copper mining companies of Lake Superior since the 1st January, 1885, of about \$13,000,000 in the aggregate.

The Plymouth Consolidated Gold Mining Company has one of the most productive gold mines in America, situated at the town of Plymouth, Amador county, California. From June, 1883, to December, 1885, both inclusive, thirty-one consecutive monthly dividends have been declared of \$50,000 each, aggregating \$1,550,000.

The *Treadwell* gold mine on Douglas Island, Alaska, to which frequent reference has been made in these columns, is now classed among the greatest producers in North America. The lode contains an enormous body of low-grade ore, which is crushed in a 120-head stamp mill, and the tailings concentrated on 48 Frae belts. The concentrates (sulphurites) carry about \$80 a ton, and are to be treated by chlorination.

PHOSPHATE PROPERTY In the Township of Portland West, FOR SALE.

Lots 25, 26, 27 and 28, in the 3rd range. Some excellent surface shows have been uncovered on these lots and only require capital for developing. Price and particulars given at the office of the MINING REVIEW.

WELLAND CANAL ENLARGEMENT.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for the Welland Canal," will be received at this office until the arrival of the Eastern and Western mails on MONDAY, the 25th day of JANUARY next (1886), for raising the walls of the Locks, Weirs, &c., and increasing the height of the banks of that part of the Welland Canal between Port Dalhousie and Thorold, and for deepening the Summit Level between Thorold and Ramey's Bend, near Humberston.

The works, throughout, will be let in Sections.

Maps of the several localities, together with plans and descriptive specifications, can be seen at this office on and after MONDAY, the 11th day of JANUARY next (1886), where printed forms of tender can be obtained. A like class of information relative to the works north of Allanburg will be furnished at the resident Engineer's Office, Thorold; and for works south of Allanburg, plans, specifications, &c., may be seen at the resident Engineer's Office, Welland.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and, in the case of firms, except there are attached the actual signatures, the nature of the occupation and place of residence of each member of the same; and further, an accepted bank cheque for the sum of Two Thousand Dollars or more—according to the extent of the work on the section—must accompany the respective tenders, which sum shall be forfeited if the party tendering declines entering into contract for the works at the rates stated in the offer submitted.

The amount required in each case will be stated on the form of tender.

The cheque or money thus sent in will be returned to the respective parties whose tenders are not accepted.

This Department does not, however, bind itself to accept the lost or any tender.

By order,
A. P. BRADLEY, Secretary.
Department of Railways and Canals, {
Ottawa, 9th December, 1885

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Public Buildings, at Peterborough, Ont." will be received until TUESDAY, the 20th day of January next, inclusive, for the erection of Public Buildings, for the

POST OFFICE

AND

The Customs and Inland Revenue Offices,

At Peterborough, Ont.

Plans and specification can be seen at the Department of Public Works, Ottawa, and at the office of J. E. Belcher, Architect, Peterborough, on and after FRIDAY, the 18th day of December next.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures. Tender for each building to be separate, and forms will be supplied for each.

Each tender must be accompanied by an accepted bank cheque, made payable to the order of the Honourable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party decline to enter into a contract when called upon to do so, or if he fail to complete the work contracted for. If the tender be not accepted the cheque will be returned. The Department does not bind itself to accept the lowest or any tender.

By order,
A. GOBEL, Secretary.

Department of Public Works, {
Ottawa, 7th December, 1885. }

GRAND COLONIAL

Exhibition in London, Eng.
1886.

FIFTY-FOUR THOUSAND FEET RESERVED
FOR CANADA.

First Royal Exhibition Commission Since 1862.

THE Colonial and Indian Exhibition to be held in London, England, commencing May 1st, 1886, is intended to be on a scale of great magnitude, having for object to mark an epoch in the relations of all the parts of the British Empire with each other.

In order to give becoming significance to the event, a Royal Commission is issued for the holding of this Exhibition, for the first time since 1862; and His Royal Highness the Prince of Wales has been appointed President by Her Majesty.

The very large space of 54,000 square feet has been allotted to the Dominion of Canada by command of the President, His Royal Highness.

This Exhibition is to be purely Colonial and Indian, and no competition from the United Kingdom or from foreign nations will be permitted, the object being to exhibit to the world at large what the Colonies can do.

The grandest opportunity ever offered to Canada is thus afforded to show the distinguished place she occupies, by the progress she has made in Agriculture, in Horticulture, in the Industrial and Fine Arts, in the Manufacturing Industries, in the Newest Improvements in Manufacturing Machinery and Implements, in Public Works by Models and Designs; also in an adequate display of her vast resources in the Fisheries and in Forest and Mineral wealth, and also in Shipping.

All Canadians of all parties and classes are invited to come forward and vie with each other in endeavoring on his great occasion to put Canada in her true place as the premier colony of the British Empire, and to establish her proper position before the world.

Every farmer, every producer, and every manufacturer, has in eyes in assisting, it having been already demonstrated that the extension of trade always follows such effort.

By order,
JOHN LOWE,
Sec. of the Dept. of Agriculture.
Ottawa, 1st Sept., 1885.

ADJOINING THE FAMOUS LITTLE RAPIDS MINE IN PORTLAND EAST.

THIS location has been pronounced by experienced practical miners one of the most promising phosphate producing properties in the district. There are over TWENTY SURFACE EXPOSURES OF GOOD PROMISE, and one deposit now being worked that proves an extensive body of phosphate AT A DEPTH OF FIFTY FEET.

Price reasonable and satisfactory reasons given for selling.

Full particulars obtainable at this office.

FOR SALE,

White Marble Quarry on Calumet Island.

At this quarry there is an inexhaustible supply of most beautiful white marble. Samples to be seen and information obtained at the office of the MINING REVIEW.

WELLAND CANAL.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Lock Gate Timber," will be received at this office until the arrival of the Eastern and Western Mails on TUESDAY, the 19th day of FEBRUARY next, for the furnishing and delivering, on or before the 22nd day of June next, 1886, of Oak and Pine Timber, sawn to the dimensions required for increasing the height of the Lock Gates on the WELLAND CANAL.

The timber must be of the quality described and of the dimensions stated in a printed bill which will be supplied on application, personally or by letter, at this office, where forms of tender can also be obtained.

No payment will be made on the timber until it has been delivered at the place required on the Canal, nor until it has been examined and approved by an officer detailed to that service.

Contractors are requested to bear in mind that an accepted bank cheque for the sum of \$600 must accompany each tender, which shall be forfeited if the party tendering declines to enter into a contract for supplying the timber at the rates and on the terms stated in the offer submitted.

The cheque thus sent in will be returned to the respective parties whose tenders are not accepted.

This Department does not, however, bind itself to accept the lowest or any tender.

By order,
A. P. BRADLEY,
Secretary.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

The opening up of new tracts of country throughout the length and breadth of the Dominion by means of railway enterprises and exploration in the interests of our lumbermen is concomitantly bringing an increased number of mineral occurrences to view. Comparatively few people in Canada seem to realize the importance to a country of encouragement to mining industry, and among certain classes mining is looked upon in no other light than that of speculation, while some people go so far as to term it a gambling operation. Farmers have been known to come to hopeless grief in attempting to prosecute farming on legitimate principles; but who will deny that the largest source of wealth is derived from cultivation of the soil? Because investments in timber limits have, in some instances, proved unprofitable, it must not be said that our lumbering industry has not benefited the country; and because the majority of mines do not pay large dividends, can we question the fact that every ounce of economic mineral brought to the surface represents so much additional wealth to the country in which it is mined? Mining is a steady source of revenue to the older countries of the world, and it might be made a very important and remunerative industry in Canada, and one that would add materially to the wealth of the Dominion. The importance of utilizing natural mineral wealth is so well recognized in Germany that the Government works the majority of the mines. In France all mining engineers

are Government engineers; and in England the Government supplies inspectors in all the mining sections, and a record-keeper to collect statistics, while private enterprise does the rest. What is the Government of Canada doing, and what has it ever done, toward furthering and encouraging the development of our mineral resources?

The vast extent of Canada's territorial possession renders it practically impossible for the staff at present employed on the Geological Survey to do more than devote attention to the geological features of the country. It is of course very important that we should have a knowledge of the geological formation of our Dominion, but that her mineralogical features should be almost entirely neglected is not to the best interests of individuals, of our people as a whole, or of any section of our community. A mineralogical and mining department should be attached to the Geological Survey, whose duty it would be to collect and dispense information relating to the mineral deposits in all parts of the Dominion, and to keep records of mining statistics. Up to the present day we have no official record of what has been accomplished by Canadian miners, and no official reports relating to our mineral deposits to which capitalists or any one who may desire to engage in legitimate mining can refer. In a few weeks the mineral resources of Canada will be represented at the Colonial and Indian Exhibition in London by upwards of 725 exhibits, which will doubtless lead to enquiry for reliable information concerning the extent and nature of the deposits. From what official records can this information be supplied? Before capitalists can be induced to invest their money in mining enterprises they must be well informed by some unprejudiced and disinterested authority, and what could be more authentic than the official reports and records of a Mineralogical and Mining department of the Geological Survey? Yet such a thing does not exist.

We have stated in former numbers of the REVIEW that capitalists are making enquiries for mineral lands with a view to investing in them and engaging in active mining operations. Such enquiry continues, but while owners of undeveloped properties hold them at exorbitant prices, capital will seek investment elsewhere and the advancement of our mining industries will be impeded. A mine may be purchased without risk as there is no difficulty in arriving at its actual value, but a prospect must be looked upon purely as a speculation; it may prove worthless and, possibly, it might develop into a bonanza. The investor who risks his money in a prospect should, therefore, not be expected to pay as much for it as he might be disposed to give for a developed mine. Capital is the agent we most require in Canada to successfully build up and develop great mining industries. With its assistance much could be accomplished; without it we are helpless to avail ourselves of the mineral wealth

which Nature has so lavishly deposited for our use. Let us, therefore, offer some inducement to capitalists to invest in mining enterprises in Canada and not drive them from us by allowing them no margin for profit on their investments.

Mr. L. H. Shirley, M. E., of Montreal, and Mr. John Lamb of Toronto have, during the past month, made an extended tour through the phosphate district of Ottawa County and visited all the mines in operation. They report having seen some promising undeveloped deposits and that a very large quantity of ore is being raised at the mines.

Dr. Selwyn, Director of the Geological Survey, sailed from New York on 11th inst. by s.s. *Britannic*. The Director has gone to England to see that everything is in readiness to receive the Canadian mineral exhibit for the Colonial and Indian Exhibition, and to personally superintend its arrangement. He will remain in England until the Exhibition closes.

Mr. T. S. Higginson returned recently to Ottawa from the Rocky Mountains, where he had been exploring for the past year, and speaks in the highest terms of the prospects for mining in that region. He has brought with him some wonderfully rich specimens of gold-bearing quartz and argenteriferous galena from discoveries he himself made, the analysis of which have shown the quartz to carry a very large quantity of gold and the galena to yield upwards of \$500 in silver to the ton. Mr. Higginson will return in the spring and proceed to open up and develop these locations.

THE PHOSPHATE TRADE.

The phosphate miners in Ottawa County have done good work since the shipping season closed last autumn, and the piles of ore that have accumulated at the various mines offer an imposing sight to people passing through the mining district. Never in the history of this industry in Canada has there been, so early in the year, such a large quantity of ore mined, dressed and awaiting shipment, as there is in stock at this date; and mine owners will not relax their efforts to keep up, and perhaps increase, the average monthly output, which, for the past five months, has run far in excess of the average for the same period in former years. Everything at present points to a largely increased production for this year, and there exists no doubt that during the shipping season of 1886 many thousands of tons will go forward in excess of last season. The quality of the ore, too, is quite up to the standard of 1885, which was as high a grade as has ever been shipped from any phosphate deposits in the world. During the past two years, owing to the attention miners have given to dressing the ore, the product of Canadian mines has found much favor abroad with manufacturers of superphosphates, and as the production increases, as it is steadily doing year by year, in the

same ratio will the industry advance in importance, until the time may arrive when Canadian phosphate will rule the foreign markets instead of the value of our output being regulated, as it is to-day, by importations into England and Europe from the mines of other countries. Miners are

PREPARING FOR EARLY SHIPMENTS, evidence of which is to be seen at the various shipping points along the bank of the river du Lièvre, where thousands of tons have already been deposited in readiness to be forwarded as soon as the ice will have left the river. Some ore has been forwarded from the mines in sleighs to the C. P. R. terminus in order that the earliest tonnage may be taken advantage of when navigation opens from Montreal in the spring; but, as this is much more expensive transportation than floating the ore in scows down the river, a small percentage of the output has been sent down this winter.

Several new mines have been opened since last season in the townships of Templeton and Bowman, some of which are yielding ore in liberal quantity and of a high grade, and promise to develop into heavy producers. The older mines in the townships of Buckingham, Portland East, Portland West, and Templeton—such as the "Emerald," "Little Rapids," "North Star," "High Rock," "Star Hill," and the "McLaurin & Blackburn" mines—are turning out more phosphate, and of a higher grade, than at any time since they were first opened. The mines are, for the most part, suitably equipped for economic mining; work is being carried on under better management, and more systematically than formerly; and the facilities now afforded for transportation have reduced this item to almost a minimum of cost; the market abroad continues steady, and it is expected that the rate of freight for the coming season from Montreal to foreign ports will not exceed that of last year. Taking into consideration all the important facts we have enumerated in connection with this important industry, it is not unreasonable to predict a most profitable season for Canadian phosphate miners.

STRIKING COLLIERIES.

Nearly one thousand hands went on strike at the Cumberland Railway and Coal Company's mines on the 12th inst. These mines have been known formerly as the Spring Hill mines, N. S., and are the largest collieries in Canada. The strike arose among the cutters working in the north slope, who complained of the unsafe condition of their working places and demanded higher pay in consequence. The manager, Mr. R. G. Leckie, would not accede to their demands and a general strike ensued. It was then proposed that a workmen's committee should be formed to examine the condition of the slope and report to the managers, who expressed a willingness to abide by its decision. Meanwhile the boiler was blown out, the fan stopped and all operations suspended. After the committee had carefully examined the cause of the grievance it decided in favor of the company and work was resumed, the men starting in again on full time. Anything in the shape of accident or strikes that occur to hamper the full working of these collieries is a serious matter and practically a public misfortune.

CANADIAN PHOSPHATE DEPOSITS.

OFFICIAL REPORT

By THOS. W. HOTCHKISS, ESQ., U. S. CONSUL AT OTTAWA.

In Mr. Hotchkiss's report to the Consular Bureau at Washington he attaches much importance, and justly so, to the rapidly growing phosphate industry in Canada. The statistics of this trade which he has embodied in his report vary somewhat from the figures which have, from time to time, been published in these columns, but they are sufficiently accurate to enable those who read them to arrive at a fair idea of the magnitude to which phosphate mining in this district will attain. Mr. Hotchkiss has advanced theories and presented many points for the consideration of those who are engaged in the manufacture of fertilizers in the United States from mineral phosphate; and, while it cannot be expected there will be a consensus of opinion on all the issues he has raised, it is not unlikely that his report will lead to close enquiry into the actual relations which now exist between the phosphate miners of Canada and the manufacturers in England, Europe and the United States, and may be the means of opening up a new market for the product of Canadian mines.

The Consul's report is as follows:—

"There are but two important industries materially affecting the interests of the United States, connected with this Consular district, viz, the manufacture of white pine lumber and the mining of "apatite" or mineral phosphate of lime.

It is within the last ten years that the discovery was made of the important deposits of apatite in the apparently barren hills of Quebec and Ontario; but for several years all efforts made in its behalf were of an experimental character, and only within three or four years has any practical development of the deposits been prosecuted, or the real value and merit of the mineral as a fertilizer been established.

When, by analysis and actual use, it had been demonstrated that this mineral was composed of 80 to 90 per cent. of phosphate of lime, the interest of wide-awake men, commercially and speculatively, was drawn towards it, until it bids fair to become a powerful factor in the industries of this section. Its development and production is rapidly increasing, and as the profits, thought to be very great, become more widely known, it is reasonable to expect a still more rapid development.

SITUATION OF THE DEPOSITS.

Examining the map of Canada it will be found that the Ottawa River is the dividing line between the province of Ontario and the province of Quebec. Crossing the Ottawa at Ottawa City (which river is navigable from Ottawa City to its confluence with the Saint Lawrence, near Montreal), we are in the province of Quebec; continuing northerly for eight miles will bring us into the township of Templeton, in the county of Ottawa, and the region of the phosphates. Go north-east from Ottawa City 20 miles, and the township of Buckingham is reached. Here will be found the best deposits that have as yet been developed. All this district lies less than 70 miles north of Ogdensburg, N. Y.

New discoveries are constantly being made, and new "phosphate properties" offered in the market. Other deposits, however, less in extent and value, are found in other parts of the Dominion.

EXTENT OF MINING.

In the earliest stages of this mining it was conducted in a rude, primitive manner, as well from want of capital as lack of the necessary experience, and as usual in such cases with doubtful success. In a few cases it must be admitted, through the failure of the deposit, it resulted in the suspension of the enterprise.

In the last year matters have immeasurably improved. British and American capitalists have so increased their means and abilities that the industry is placed in a lucrative condition.

SHIPMENTS OF PHOSPHATE.

The following table will show the shipments from Canada for the past three years of crude apatite:—

Years.	Quantity.	Value.	Value at Montreal.
	Tons gross.		Per ton.
1882	16,585	\$333,019	\$20 08
1883	19,466	421,963	21 67
1884	23,000	519,000	20 25

The shipments for 1885 are known to exceed 25,000 tons. The district alluded to mined in 1884 20,353 tons, the balance of the output for that year going from the smaller workings along the Rideau canal in the vicinity of Kingston.

When the Canadian phosphates were first introduced in the market they were naturally looked upon with great suspicion, through a want of reliable knowledge of their value as a fertilizer; but at this time the condition is entirely reversed, every pound of the output being contracted for in advance of its production.

As mined it is of every shade of color, from a light gray to nearly black. From irregular "pockets" in small deposits, as well as in large blocks and masses, in apparently inexhaustible volume—superficial, shallow, and down deep in the bowels of the hills—now mixed with pyroxenic rock, gneiss, mica, etc., which usually accompany the deposit in this country, to solid masses of almost pure phosphate.

QUALITY OF THE DEPOSIT.

Being a more concentrated phosphate than is known to exist in quantities in any other part of the world, it is greatly sought for to bring up the acid phosphate fertilizer to a high percentage of phosphoric acid.

Regarding the value of this "apatite" as a fertilizer, a reliable authority states that Canadian phosphates contain 89.91 per cent. of tri-basic phosphate of lime, according to a most authentic analysis. A comparative table of the analytical composition of phosphates recently published shows that with the exception of three limited deposits in the West Indies, and one in Spain, the Canadian apatite ranks the highest. Also recent foreign official reports show that in those portions of Europe where the sugar-beet is extensively cultivated—France, Belgium and Denmark, notably in France—no fertilizer has been found to equal the mineral phosphates of Canada.

MARKETS.

To the present time the demand has been entirely European, mainly in Great Britain and Germany, though France would take the entire output if she could secure it.

But 254 tons in 1883 and 221 in 1884 went direct to the United States, while Great Britain exported to the United States in 1883 1,262 tons of crude and 7,766 tons of manufactured or superphosphates—this latter (and possibly the "crude") undoubtedly being Canadian crude chemically treated and returned to America.

The statement of a member of the Canadian Geological staff, that "much of the material mined in Canada, sold and exported to Europe, has been and still is re-shipped to the United States, either in a raw or manufactured condition," confirms what the statistics seem to show. Mr. Torrance, of the Canadian Geological Survey, in his last report on the phosphates of this district, also states that "as 1,262 tons of crude phosphate and 7,666 tons of superphosphates were imported into the United States from Great Britain last year, it is highly probable that a very considerably quantity of our Canadian apatite has been used in enriching American lands, after a voyage across the Atlantic and back to the United States."

Here we have indubitable authority that this state of affairs prevails. Does it not become us speedily to seek the cause? It is surely extraordinary in the face of the admitted shrewdness of even the average American merchant. Does it not also suggest the possibilities for fraud and adulteration?

Is there not in this risk alone sufficient to appeal to the intelligence and shrewdness of the American dealers in phosphates and fertilizers? If not, let us see what benefactors our German friends are to the agricultural interests of the United States. This may assist towards sounder views of "protection."

IMPORTS OF PHOSPHATES INTO THE UNITED STATES.

The importation of crude phosphates into the United States in 1883 and 1884 from all countries was as follows, viz:—

Countries.	1883.		1884.	
	Tons.	Value.	Tons.	Value.
Danish West Indies	275	\$ 865	240	\$ 1,563
France	102	682
Germany	44,033	367,970	10,181	63,747
England	1,262	24,081	8,567	156,772
Canada	254	4,420	221	4,025
British West Indies	2,547	25,088	1,375	9,270
French Guiana	250	2,059	125	500
Haiti	235	1,767	590	2,330
Cuba	199	857	81	491
Porto Rico	231	1,625	530	5,115
Dutch West Indies	2	26
Total	49,331	\$429,391	21,910	\$243,843

Average value, per ton—1883, \$9.78; 1884, \$11.08.

The foreign buyers of Canadian phosphates pay from \$12 to \$18 per ton for it here, and have paid \$20 for 80 per cent. phosphate, delivered on boats at the river (to be taken to Montreal for ocean shipment).

The table shows that the average value delivered in the United States from England, Germany, etc., was \$9.78 and \$11.08 per ton for the years 1883 and 1884 respectively, and also states the market value here, where produced, about \$13 per ton (never less than \$12 per ton) for 80 per cent. phosphate. I ask: on what hypothesis or by what method of higher arithmetic can this character of commercial traffic be satisfactorily explained other than through the medium of gross adulteration?

By the table given of Canadian production it will also appear that the Canadian phosphates would have supplied one-half the United States demand in 1883 and the entire demand in 1884.

But again, to summarize the case, it apparently shows that the average cost of Canadian crude, as paid by the foreign buyers in 1883, was \$21.67 per ton; that the average value as entered in United States customs, imported from foreign countries in 1883, is \$9.78. It was purchased in the lump, freighted to Europe, there crushed and pulverized by grinding or otherwise, and returned to the United States valued at half its original cost.

When we consider that Canadian phosphate yields 75 to 90 per cent. of pure phosphate of lime, and that its equal in purity is not found elsewhere in any appreciable quantities, is it not

surprising that its intrinsic value should be so little recognized by those who require it to the extent which characterizes the known wants of American agriculturists? And, too, when by a little effort on our part (I speak as an American) every pound needed can be mined here by American industry, placed direct in the American market in its purity, and at a largely reduced cost, quality considered.

MINES.

The Emerald and Star Hill mines, owned and worked by American capitalists, it is stated paid dividends of 30 per cent. to their shareholders last year.

The High Rock mine is owned and worked by an English company, while several smaller interests are worked by individual Canadian enterprise. Up to October 1st, 17,853 tons had gone forward during the present season.

The system of mining is constantly being improved as experience dictates its necessity, the variability of its stratification compelling frequent changes in method in the interest of economy.

The larger portion of the productive workings are on the bedded deposits; these, however, for the most part are opened only by shallow pits, a condition of things which is explained by the peculiar character and the frequency of the deposits, as also by the economic value of the apatite reached.

This mineral, unlike ordinary ores, is in its crude state a merchantable article of considerable value locally, and finds a ready sale even in small lots of 5 and 10 tons.

The average cost of mining at the better developed deposits is said to be about \$3 per ton, gross. Three to four dollars per ton will place it in Montreal for foreign shipment, or thence by the Lake Champlain route to New York; or about the same cost will put it at any of the shipping points between Montreal and Kingston, on the St. Lawrence River, for re-shipment to the frontier ports of the United States, on any or all the lakes to their western limits. It is well known that any freight of this character moving west by water is carried at nominal figures for its benefits as ballast.

USES OF PHOSPHATES.

The demand for proper fertilizers is limitless, and must remain so.

"The grain exported from Montreal alone, in a single year, has been estimated to contain 2,574 tons of phosphoric acid, which implies the total exhaustion, so far as phosphates are concerned, of 75,000 acres of wheat land, the renewal of which would necessitate the application of 6,000 tons of phosphates." If this be true—and it comes from the highest authority—what could be written of the stealthy exhaustion of the great agricultural districts of the United States, and their present and future necessities?

What possibilities through this crude mineral await the redemption of those hundreds of thousands of acres of once valuable Southern lands "corned to death," and now lying to waste in worthless "sage grass," begging for buyers at \$1 per acre and even less?

What possibilities also await the enterprising American who shall engage in this business of bringing this wealth, now hidden in these mountains, to the doors of the American agriculturists?

OPPORTUNITY FOR AMERICAN CAPITAL.

If any prejudice exists as regards Canada, its climate, or its people, I answer that it is misplaced. The people may not be quite as bold and venturesome in enterprise as Americans, but are just as reliable and industrious, and as fully appreciate the dignity of labor.

No people under the sun entertain a more friendly or more exalted regard for the Americans and their characteristic vim, push, energy and shrewdness, than do the Canadians. This is outspoken and unquestionable. There is no class of newcomers who will be more heartily welcomed than the enterprising American. The general good health is seen in the countenances and in the actions of the people. The school system is in all respects fully equal to the educational facilities of the United States. The habits, customs and social atmosphere of the Canadians will not be found uncongenial to Americans.

The cost of living is fully equal in all respects to that of any portion of the Northern States, but not greater. Taxes are a trifle lighter.

Mechanical and day labor does not materially vary from that prevailing in the State of New York, outside of New York City. Shipping facilities are first-class, and freight rates are in general keeping with the ordinary course of rates in the Northern States, which is the natural result of that grand system for transportation so liberally fostered by the Dominion government.

I cannot close this already lengthy report without calling especial attention to the apparent apathy of American capitalists towards this enterprise, which not only promises such remunerative results, individually and commercially, but which is of such vast importance to the agricultural interests of the United States.

If the statements made and statistics given are reliable, is it creditable to the alleged business sagacity and far-seeing and far-reaching proclivities which are supposed to be so characteristic of the typical American, that this apparent non-interest should exist towards this promising enterprise?

The United States Government admits this article free of duty, and the Canadian government and people are inviting us to come and get it. Neglecting to do this, we are allowing Continental Europe to gobble every pound of the production, pay the freight twice across the ocean, with all the incidental expenses attached to such procedure, and with no known check on its adulteration we complacently purchase it at last at a value that necessitates its re-sale to the agricultural community at a price that virtually amounts to prohibition.

I ask, are not national as well as commercial issues involved in this matter?

(Signed) THOS. W. HOTCHKISS.

United States Consulate,
Ottawa, November 23rd, 1885.

ASBESTOS MINING.

This has become one of the most important industries of the Eastern townships, and the annual production of asbestos of superior quality is increasing year by year. In a few years hence the shipments from the various mines will doubtless have assumed large proportions, as the deposits are sufficiently extensive to be capable of yielding this valuable mineral in much greater quantity than miners have yet attempted to produce. For the season of 1885 the shipments from the district aggregated about 1,500 tons, to which the following mines contributed, approximately, the amount set opposite their respective names:—

Johnson's Company mine..... 383 tons
Boston Asbestos Packing Co.'s mine. 379 "
King Brothers' mine..... 198 "
Ward mine..... 102 "

The ruling price obtained for the output of last season was \$80 per ton (2,000 lbs.) delivered

on the cars of the Quebec Central Railway, which runs alongside the mines, as it came from the pits, without classification of quality. Work at these mines is usually suspended about the 15th November of each year and resumed about the 15th April following. It is thought, however, that operations can be prosecuted profitably the year round, and the experiment is being tried the present winter by the Anglo-Canadian Asbestos Company at its mines at Black Lake. If this company can successfully demonstrate the practicability of mining asbestos to advantage during the winter months, other mine owners will of course follow its example and the industry will thereby be greatly stimulated. The quality of the mineral has gained a world-wide reputation, and as the production increases so will the demand expand in like proportion.

MICA IN CANADA.

It is within the past two years that mica of the best quality, known as *Muscovite*, has been discovered in Canada in marketable sizes and in paying quantity, and to-day we know of several deposits capable of being developed into fairly productive mines. Two in the county of Frontenac, province of Ontario, show well-formed, large crystals at the surface embedded in white quartz; another in Wakefield, county of Ottawa, has been uncovered and numerous crystals have been exposed, which, though small, are of excellent quality; in the Lake Superior and Lake of the Woods districts good mica has been discovered in paying quantity, and a company has been formed in Winnipeg to work an important deposit in the last mentioned locality. In British Columbia also a fairly good quality is known to exist, but no attempt has yet been made to prove the sizes of the available crystals or the extent of the deposits in that province. Some small amount of development work has been done on a deposit about 60 miles from Berthier, east of Montreal, but work has for some time been suspended at this point for reasons unknown to us. The *Villeneuve* mine in the county of Ottawa, of which mention has frequently been made in these columns, has been worked continuously during the past year and has produced many thousands of pounds of mica, perfect in quality, and in sizes varying in dimensions from the ordinary sized sheets used in stoves up to plates measuring 14x12 inches. This mine yields a steady output, and with a little more development will be capable of yielding an almost unlimited annual production. Some specimens of mica have been forwarded from the Villeneuve mine to the Colonial and Indian Exhibition, and we will be much disappointed if they are not pronounced by judges to be of equal quality to any that is produced in any quarter of the globe. Samples that were sent to the Antwerp Exhibition last year created much surprise among the mica dealers of Europe, some of whom expressed a preference for its quality before what they had been receiving from East India and North Carolina.

EXPORTS OF IRON AND STEEL FROM GREAT BRITAIN TO THE UNITED STATES.

	Eleven months ended Nov. 30.		
	1883.	1884.	1885.
	Gross tons.	Gross tons.	Gross tons.

Colonial and Indian Exhibition.

Canadians, especially those who are interested in the mineral resources of the Dominion, will be gratified to learn that their country will, in all probability, take the lead with her exhibit of the product of the mine at the great Exhibition which will open in London, England, on May 1st. During the past decade of years the mining industries in Canada have advanced so rapidly that we are able to-day to send to London upwards of 725 exhibits of ores and minerals and their products, whereas but 549 specimens were exhibited at the Centennial Exposition at Philadelphia in 1876. To this department each of the provinces, with the exception of Prince Edward Island and Manitoba, has contributed very creditable exhibits, which will, no doubt, be carefully classified and arranged on their arrival in London, so as to be seen to best advantage, under the supervision of Dr. Selwyn, Director of the Geological Survey, and his able assistant, Mr. Chas. W. Willmott, who will shortly proceed to England to take charge, under Dr. Selwyn, of Canada's mineral department in the Exhibition. As far as we can learn the different provinces have forwarded mineral exhibits as follows:—

NOVA SCOTIA.

Gold, Silver, Copper, Antimony, Lead, Manganese, Iron, Coal, Gypsum, Barite, Infusorial earth; also building materials—such as Granite, Sandstone, Brick, Drain Tiles and Lime. This province will be well represented and her exhibits will be as attractive as those from any of her sister provinces.

NEW BRUNSWICK

has forwarded exhibits of Copper, Antimony, Manganese, Iron, Coal, Albertite and Infusorial earth; besides granite columns, red and grey, from the St. George quarries, and the products of other quarries, all dressed to show tooling, etc. The province of

QUEBEC

has contributed Gold Nuggets from Beauce district, Copper, Antimony, Nickel, Manganese, Iron and Chromic Iron ores; also a fine exhibit of Apatite, Mica, Asbestos, Graphite, Celestite, Magnesite, Soapstone, Potstone, Felspar and Iron Ochre. Amongst the above are some rare and very valuable specimens—notably a solid block of graphite, forwarded by Mr. Walker of this city, weighing 3,000 lbs.; a specimen of apatite, from the McLaurin & Blackburn mine in Templeton, weighing 1,600 lbs., and a magnificent apatite crystal weighing 500 lbs., the property of Mr. W. A. Allan of Ottawa. In addition to the foregoing there are some fine specimens of marble, cut and polished, together with samples of Granite and Porphyry from various parts of the province. The Canadian Granite Company, whose extensive works are in this city, have exhibits of beautifully dressed and polished granite, marble and serpentine columns from their own quarries, and some artistically turned serpentine card receivers. Quebec also forwards a vast variety of specimens of her building stones dressed to a uniform size and showing the various dressings, thereby enhancing the value of superior stones and detracting from those of an inferior character.

ONTARIO.

This province has sent Gold-bearing and Silver-bearing ores and some very fine specimens of the Sulphide of Silver from Rabbit Mountain (Lake Superior District). Lead, Copper and Iron ores are also well represented, the latter by about 40 specimens from all parts of the province, weighing from 50 to 300 lbs. each.

A handsome specimen of Barite from Pakenham, pure white, is worthy of mention. Gypsum from Brant county and neighborhood, Salt and Brine, Apatite, Mica, Molybdenite, Pyrite, Pyrrhotite, Kaolin and Lithographic stone are among the exhibits. Besides these there are some fine columns of marble and granite and dressed building stones from a large number of quarries, many of which cannot be surpassed for beauty. Mr. Waterman of London, Ont., has forwarded a large exhibit of Petroleum and its products. Brick and Drain Tiles, for which the province is famous, are also well represented, and it is expected that a large collection of mineral specimens will be forwarded from the Thunder Bay mining district. From the

NORTH WEST TERRITORIES

there are some fine specimens of Coal, taken from the Galt and Banff mines and from other localities; and

BRITISH COLUMBIA

contributes a collection of Gold from numerous claims, Silver-bearing ores, Copper (native and sulphide) and Iron ores. She also sends fine specimens of Coal weighing from two to four tons, including anthracite from Queen Charlotte Islands. These, in addition to cut and polished blocks of marble and cubes of building stones, make for our western province a good display.

The foregoing will give some idea of the extent of the Canadian mineral exhibit. The care with which all the specimens have been selected is sure to make this department one of the most interesting of the Exhibition and should attract foreign capital to the country for the development of our vast and rich mineral deposits.

HURONIAN MINE.

Frequent reference has been made in these columns to the operations which have been in progress at this mine during the past year or more, and it will, therefore, be of interest to some of our readers to know the present condition of the mine, and to learn of the many natural advantages the property possesses as a mining location.

The *Huronian* gold and silver mine is situated 75 miles from Port Arthur, to the westward, and 50 miles from Savanne station, a point on the Canadian Pacific Railway. During the past year this mine, at which there is a ten-stamp mill, with amalgamated copper plates for free milling and Frue vanners for concentrators, has been tested by its own mill-work with most satisfactory results, and proved to be a very valuable property, capable of a large production, and for which the mine is being developed and equipped. The main shaft is down 150 feet, and a second level has been started. The aggregate of the levels already driven is 260 feet, and a winze, now being sunk to meet the first level, is down 75 feet. The mill tests have shown that the entire vein-stone of the lode is pay-ore; and the vein, which is a true fissure cutting the stratification of the Huronian talcose slates, which form the country rock, has an average width of 5 to 6 feet. In places this vein produces rich sylvanite ore, a compound of gold, silver and tellurium, which is selected for smelting without being put through the mill. The vein-stone is uniformly charged with sulphurets, besides showing a considerable sprinkling of free gold. Not long since a segregated vein, large and rich enough to be worked profitably, was discovered, running with the formation and joining the main fissure about midway between the shaft and the mill. Near the point where it intersects the main vein the winze is being put down,

it being thought desirable to find their junction in the drifts to the south-west, where an unusually rich body of ore is supposed to exist.

The property is well supplied with good timber for fuel and all mining purposes, and a saw-mill attachment to the stamp-mill produces all requisite lumber. A small stream runs through the property in a valley which forms an excellent meadow for hay and pasturage; and on the location, which covers an area of 160 acres, there is good arable land for the production of cereals and root crops. The mill is supplied with water from a small lake on high ground near by, and in every way the mine is admirably situated for working. These important advantages, together with the fact that the veins are so reliable, render it not unlikely that the *Huronian* will make for itself an enviable name as an extensive producer and a dividend-paying mine.

A company has applied for a charter for a railway to connect this mine with the Canadian Pacific Railway and Port Arthur. It is expected that the line will be in course of construction within a few months, and when completed it will not only be of great service to the owners of the *Huronian* mine, but will pass through the new silver region to the west of Port Arthur and supply the miners now working there with railway facilities, of which, at the present time, they are seriously in need.

"PAY STREAKS."

NOVA SCOTIA GOLD FIELD.

By G. Henry Kinahan, M.R.I.A., etc., Dublin, Ireland.

To the *Editor Canadian Mining Review*.

In the paper on the Nova Scotia gold mines read before the meeting of the American Institute of Mining Engineers at Halifax, Mr. Gilpin regrets that no deep sinking has ever been made below the *pay streaks* to learn whether they set on again or not in depth. I, however, would suggest that perhaps drivings or cross-cuts might be better, if made across the quartz lodes whenever the *pay streak* thins out, either in depth or length. The accompanying rough sketch will represent either the plan or the vertical section of a quartz lode:—

In its shrinkage fissures formed (A, A, A, A, A, A), to be subsequently filled with minerals or metallic ores. Such fissures are not uncommon in lodes, the so-called "strings" or "leads" in many lodes being filled up small fissures of this class. They, however, in some ground occur of a magnitude sufficient to be compared with the *pay streaks* of the gold miners, as was the case in the *Cronebane* mine, Ovoca, Co. Wicklow, Ireland. In this mining sett there is a wide mineral channel made up principally of "iron-masked" or pyritous rocks. On or along the north or "footwall" of the channel lay the "great sulphur lode" (iron pyrites), while in the ground between the sulphur lode and the south or "hanging-wall" the copper lodes occurred. The latter appears to me important, as the mode in which they occurred may bear on the nature of the *pay streaks*.

The *Cronebane* copper veins occurred in vertical lentils of various thicknesses, lengths and

depths, that, nearly invariably, gradually died out; the paying portion of one lentil seldom overlapping the paying portion of the next.

SURFACE

Longitudinal plan showing cakes of copper ore in four distinct lentils and the mode of the overlaps. In the mines the lentils were usually much greater in length than in depth.

Experience taught the miners that it was a waste of time and money to follow a lentil in depth or length; while if they drove horizontally across the ground they might come to a "copper streak," on following which they came to a paying lentil.

It is evident that the quartz veins of Nova Scotia must have shrunk, as otherwise the lentils now occupied by the *pay streaks* could not have been formed. During the shrinkage of the quartz vein one continuous fissure might have formed; this, however, does not appear to have been the case in any recorded instance; therefore it is natural to suppose that, as at the *Cronebane* mine, a number of minor fissures were formed, each one beginning in length or depth at or near the end of that in its neighborhood, as roughly represented in the sketch. To test whether the *pay streaks* are of a similar nature to the copper veins of *Cronebane* should not cost much time or money, and if the trials were successful the resources of this field would be considerably augmented.

I may mention that in depth the *Cronebane* copper lodes were cut out by the sulphur lode underlying considerably southward—a string coming into the vein from above (a "feeder") made the vein rich, while a "dropper" or one going down from the vein, made it poor.

Vertical lode with a "feeder" and a "dropper," *Cronebane* mine, Ovoca, Co. Wicklow, Ireland.

Copper Smelting at Sydney Harbor, Cape Breton, N. S.

The proposed operations of the Coxheath Copper Company at their property on Sydney Harbor, Cape Breton, include a railway, narrow gauge, about six miles long, from the mine to Sydney Harbor, a large smelting furnace, and an extensive refining and concentrating establishment. The shafts are to be deepened and levels started to yield 100 tons of ore a day. The natural facilities for smelting copper ore in Sydney Harbor are unsurpassed even by far-famed Swansea. The coal seams yield an excellent coke, one ton of which will smelt eight tons of ore. Limestone and iron ore are abundant in the vicinity of the furnace site. Already foreign miners and exporters of copper ores are enquiring about the terms on which their ores can be purchased by the Coxheath Company, who feel confident that with the natural facilities of their ores and position they can deliver *matte* or refined copper to the English or Continental markets at figures far below those now quoted.

CORRESPONDENCE.

Iron Smelting in Nova Scotia.

Editor Canadian Mining Review.

HALIFAX, N.S., January 31st, 1886.

DEAR SIR,—The question of iron smelting has, as shown by Mr. Bartlett's paper referred to in your last issue, long engaged the attention of Canadian speculators. At present I believe that in Nova Scotia only is there any iron smelting. A review of Mr. Bartlett's paper speaks of the Londonderry Iron Works as if from their start some thirty years ago large expenditures had been continuously made on them. I have always understood that the early operations for the manufacture of charcoal pig were economically and successfully conducted, and I know that the troubles did not begin until the attempt was made to erect a large steel-making plant. Owing to well understood reasons, large amounts of capital were unnecessarily expended, and the problem of steel making was not solved. For several years past the furnaces have made large amounts of excellent pig, which has been largely made into bar iron, and the present "liquidation" is for the purpose of re-arranging the company on the basis of iron, not steel making. Should the contemplated amalgamation with the Springhill Collieries be consummated it is expected that the place will be remodelled to meet the present requirements of the Canadian iron and steel trade. Experience has shown that iron can be made here at cheap rates, but the difficulty has been the low price of English pig, and the nominal freights on it from Liverpool to Quebec and Montreal, which allow it to be carried as ballast. There are also other difficulties incident to breaking in on the relations between sellers and the English makers which have retarded the progress of Nova Scotian iron in the upper provinces. However, it is certain that the quality of the Londonderry iron made from a high grade ore is gradually gaining for it a sure foothold in our various markets, and as the prices of English iron appear to have reached the lowest point, the prospects are that the Nova Scotia iron business will have a good future before it. X.

MANCHESTER, ENGLAND,
January 15th, 1886.

Editor Canadian Mining Review.

SIR,—In your issue of November, 1885, I have read an article entitled "*A new use for Asbestos*." I have used asbestos for the past four or five years in my own print works here in the manner described, viz., for covering rods where exposed to steam, and have found it to answer the purpose very well. It never wears out, but becomes so soiled with color that it would stain our goods, and we are obliged to renew it on that account.

In the same issue of your paper, as well as in the January, 1886, number, attention is called to a material known as *mineral wool*, which you have described as an excellent non-conductor, and to this I beg to take exception. *Mineral wool* does not possess "excellent non-conducting qualities." I have had steam-pipes and a steam-boiler covered with it, and in the case of the boiler I did not find it to answer the purpose as well as *saw-dust* used in the same way.

A. B.

Our correspondent's opinion of the value of *mineral wool* as a non-conductor is strangely at variance with the opinions expressed in letters from engineers and others addressed to manufacturers of this material, and on which the articles in question were based.—[Ed.]

CORRESPONDENCE.—Continued.

SOCORRO, NEW MEXICO,
January 28th, 1886.

Editor Canadian Mining Review,
Ottawa, Canada.

Sir,—In reply to your remarks on the Canada Consolidated Gold Mine, in Hastings County, Ontario, as expressed in the issue of your paper for the present month, I beg to say that I have been well acquainted with this property; also the old "Dean & Williams," the "Fiegl," "Richardson" and several others in the townships of Marmora and Madoc, and know their ores as far back as 1875. Considering their favorable situation, in the midst of an agricultural and lumber country; the cheapness of labor, fuel and material; the large size and richness of the veins, and other advantages, nothing has been needed but good practical management and economy to make these properties productive and paying mines. In the case of the "Canada Consolidated," with a fine reduction plant and plenty of working capital, it should have always been a dividend-paying property instead of a drain on the pockets of the shareholders.

As there is nothing in the ore that requires more than careful milling, elaborate and costly machinery only serves to lose that which it is supposed to save, besides making the operation expensive. In 1876, in the "Fiegl" mill at Malone, I demonstrated the fact that ores from the old "Dean & Williams" and "Gatling" properties could be profitably worked. The "Fiegl" property, which had been considered worthless, I worked successfully for more than a year with an old rattle-trap mill with no other machinery than an engine and two cracked five-stamp batteries, with little or no capital at my disposal, and the ore was not as rich as that taken from the "Gatling" and "Dean & Williams" properties.

It is very evident, by your showing, that there must be loose and extravagant management where a vein with an average width of seven feet, yielding \$15 in gold and rich in arsenic, is not worked at a profit. The arsenic alone contained in the ore would yield a profit under intelligent and economical management, and in this far-away and expensive country such a property would be considered a *bonanza*. With the facilities and advantages enjoyed by miners in the district which I have already referred to, the gold ores of North Hastings can be treated at a cost not exceeding \$6 per ton.—

DONALD McRAE.

THE ONTARIO GOLD MINING COMPANY.—This is the name under which an association has been formed and incorporated under the laws of the State of Michigan to carry on a general mining business in the United States, and starting with property located in Boulder county, Colorado, with the chief business office at Toronto, Canada, but with a branch office at Detroit. The directors are Alfred H. Page, president; James Patterson, vice-president; Clarence J. I. McCraig, secretary; Liscum R. Paige, general manager and treasurer; and Jas. S. Gavin, of Toronto and J. W. Fletcher, of Detroit. The capital stock is \$2,500,000 subdivided into 100,000 shares of the par value of \$25. Twenty thousand shares of stock have been placed in the treasury as the base of a working capital. The general manager, it is stated, has twelve years' experience in Arizona, California and Colorado.

Specimens of iron brought from Greenland, and hitherto assigned to meteoric origin, are now found to be part of the products of the country.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

How Silicates rank in the Mineral Kingdom.

One very evident fact, the mere tyro in the study of nature cannot fail to observe, namely, the constant gradation and progression of more and more perfect beings in the immense scale of the Creator's works. Take for instance the animal world. At one end of the series, what do you meet? Organisms so imperfect as to call in question their right to be classed with living beings. In them all the organs are simplified and few in number. Nutrition, sensation and motion must in turn depend upon the same organs, for nature has refused them separate means of operation. One step higher and we report progress. The process of nutrition has its own organ, the body cavity; and even in the next higher class the body cavity is reserved to more general purposes, and the animal is supplied with a distinct alimentary canal. The student in zoology can pursue this ascension into the higher grades of animal creation, till he comes to a class clearly distinct from all its predecessors—the vertebrates. In these he finds a superior system of sensation, served by a most perfect nervous organization, and protected by that most admirable of all structures, the vertebrate skeleton. Now it is evident that a scientific classification is not a classification at all unless based upon nature. Such men as Cuvier could not have ignored this elementary maxim. They were too familiar with the ways of mother nature, not to fashion their system of classification in such a manner as to bring forth as much as possible the wonderful gradation just alluded to. Hence that admirable classification which enables the youngest student to take in at a glance the whole order of the animal creation; a classification which satisfies the more advanced student and is a sure guide to the original investigator who treads unaccompanied the new and immense fields of natural science.

Can Mineralogy boast of such perfection in its system of classification. At first sight we give it credit for extreme simplicity, but we are soon impressed by its most intricate complexity. Mineralogists have adopted two different methods of classifying minerals, both based nevertheless upon the same principle so that whatever is said of the one is sure to apply to the other. All minerals are immediately grouped according to one of the elements they contain. If the acidic element be chosen we have as many groups as there are negative elements. The entire kingdom is then subdivided into oxides, chlorides, sulphates, carbonates, silicates, etc. If on the contrary we adopt the basic ingredient the number of positive elements determines the number of distinct groups; hence the calcium, the strontium, the iron, the copper, the manganese groups, etc. How different from the classification in zoology and botany! In Mineralogy there are no such divisions as sub-kingdoms, classes, orders or families. The kingdom is immediately subdivided into genera. As a natural consequence the continual gradation which we remarked in

the other system, is entirely absent. All these groups are on an equal footing. Whilst in the classification of animals, a superior class is found by adding to all the essential qualities of the inferior one, some new property which gives it its title to superiority; in Mineralogy no group borrows from another. Standing on the merits of their respective elements none of which has any right to lord it over another, each stands aloof single in its constitution, unsurpassed in its perfection without a superior or an inferior. All are equal, presenting in fact such a model as a nihilist or a communist might dream of for a democratic government.

But why complain? Is not this system the only one possible for minerals? Does it not come from nature itself? If so we must be silent, as all attempts to improve or correct nature must need prove abortive. Yet the defects of the system are painfully evident. Shall we lay them at nature's door? I say we ought not. The very fact that nature has suggested a completely different order in the other kingdoms strongly favors the presumption that she does likewise in the mineral kingdom.

But we are not trusting solely to presumptive argument. A cursory review of the mineral world will suffice to show that if the universal law of gradation is absent from the class of minerals, the fault is ours, not nature's. We should not forget that Chemistry and Mineralogy are inseparable and therefore that it is in the light of chemical principles that Mineralogy is to be studied.

The first class of mineral bodies which we meet in nature comprises the elementary bodies, consisting of atoms all of one kind. Simple in their constitution they are also remarkably similar in their mode of occurrence, and what is of still greater importance similar in this crystalline structure. One instance out of many will suffice to illustrate this observation. All the metallic elements which occur native, crystallize in cubes or octahedrons of the first system; with only three exceptions and these three: arsenic, antimony and bismuth, take the form of a rhombohedron which to all intents and purposes might be called a cube as its angles are very nearly right angles. Leaving aside the elements, we meet with minerals composed of two different elements. These are not only more complex in their constitution but they exhibit a greater variety in their crystalline forms and comprise classes of great importance owing to the number of minerals they contain and the many interesting laws both chemical and crystallographic to which they conform. The mere mention of oxides and sulphides will suffice to call attention to the vast importance and decided superiority of this second group.

But we have not yet reached the summit of mineral perfection. Heretofore we have had none but minerals of a constant chemical composition; that is, minerals containing the same elements in the same proportions so long as the identity of the species is preserved. We now come to another class in which we find that perfect chemical constitution and perfect crystalline form, which are the two only perfections that minerals are acknowledged to possess. This is the class of the ternary compound substances in which chemical affinity, no longer restricted to two elements, asserts itself in the combination of two or more binary compounds. The most remarkable of this class are the carbon compounds and the silicates, both eminently characteristic of this third and highest group of mineral substances. Between these two groups the analogy is most striking. Their fundamental elements, carbon and silicon, are closely

allied. Both have a high and varied equivalence, which is an essential condition for producing a multitude of compounds with each of the other elements. Both elements are abundantly distributed in nature. It is almost exclusively in these two series of compounds, namely, hydrocarbons and silicates, that we find that wonderful variety of chemical composition which corresponds to a single simple formula. In them, too, were first observed and afterwards perfectly established those laws of multiple proportion and replacement by mutual equivalence, which the great chemists of the latter part of this century have illustrated.

The narrow limits of this article must exclude many interesting observations that might be made upon the beauties of chemical formulas; the nice distinctions that determine the fixed boundary between bi-silicates, uni-silicates and sub-silicates; the greater perfection of crystallization in carbon and silicon compounds corresponding to greater perfection of chemical constitution, and those mysterious relations between chemistry and crystallography which they partly reveal and which very probably hold the key to the future science of mineralogy.

A cursory treatment of these very comprehensive questions would fail to do them justice, but the mere mention of them is sufficient to remind the specialist of their importance in connection with the subject of this paper. Enough has been said however, I presume, to convince the intelligent reader that the very constitution of the silicon and carbon compounds entitles them to a superior rank amongst inorganic beings. But if these two groups possess so many traits of similarity, they differ as regards the end for which they have been created. The carbon compounds being of organic origin constitute that numerous and continually increasing series which result from the union of chemical force with that other still more incomprehensible activity which is called life. The silicates, on the contrary, are almost entirely absent from organic bodies; and whilst carbon reigns supreme in every realm of life, silicon sways the sceptre in the purely mineral kingdom.

The more we study silicates, the more we are convinced that they are the minerals *par excellence*. We may be mistaken, but still we cherish the illusion. A great naturalist has said that in a certain sense the vertebrates alone deserve the name of animals, because in them solely are developed not only the essential character of animal life, but also that perfect organism which contributes so powerfully to the harmonious working of perception which is the specific property of animals. We would say that silicates alone deserve the name of minerals.

First, they have, with few exceptions, resisted the attempts which have been made to produce them by artificial methods. They are nature's own masterpiece, and she is reluctant to reveal the secret of their formation. Again, the ultimate perfection of the mineral is its crystalline structure. The more symmetrical its development, the more varied are the forms it assumes under one fixed and invariable law, and the more it approaches the ideal of a true mineral. Of course it is true that nearly all minerals show a crystalline form; and many, such as calcite, have it with a perfection and variety which is not surpassed by any silicate; but even calcite, when it becomes limestone, assumes such massive forms as to disguise its true crystalline beauty. Not so, as a rule, with silicates. Even when occurring in large dykes they preserve their crystalline structure, very imperfect sometimes, as might be expected, but asserting itself at the first opportunity in the crevices and cavities of the mass in the form of splendid little crystals,

which reveal all the geometrical beauty it had been forced to conceal.

Besides, the immense number of the silicates will always make it at least an awkward task to place divisions which include three or four species on a level with one which contains by far the majority of all the mineral species known. Nor can we ignore the important part played by the silicates in the inanimate world. What is that solid crust composed of, which, we believe, separates us from the ocean of fire which is ever rolling its huge waves beneath us? What substances have contributed most to the formation of those vast mountains which form the backbone and ribs of the continents? What material is that book of solid rock made of wherein the past history of our planet has been written by the hand of death? Silicates, yes silicates, the ubiquitous, all-enduring, grand old silicates.

It is among the silica compounds that with very few exceptions we find the gems, those marvels of the mineral world which astonish the scientific analyst still more than the proud possessor who wears them for their brilliancy and beauty.

One word more. In the animal world we divide all animals into vertebrates and non-vertebrates. All the invertebrates possess more or less of the properties peculiar to animal life; but the vertebrate adds to all other perfections that of its solid interior structure. In the same manner, in the mineral kingdom, elements either by themselves or by combination form all the various species which may be called non-silicates; but when silica enters into their constitution, combining with almost every element, it forms another and higher group of minerals, all of which contain that important factor called silica, and possess as a group such distinctive and important characteristics, that I have no hesitation, and trust my readers shall have none, in regarding them among minerals as vertebrates among animals—that is, as the highest sub-kingdom in the kingdom.

SCIENTIFIC NOTES.

Dr. J. Pelletan, writing in *La Nature*, has lately given to the scientific world a description of the Bertrand mineralogical microscope, just constructed in Paris. This instrument which is one of great accuracy is 23 inches in height. The tube does not draw out. The instrument can be moved quickly by means of a rack, and slowly by means of a screw, having a pitch of $\frac{1}{125}$ of an inch. On the head of this screw, is a division with an index estimating movements of $\frac{1}{2500}$ of an inch. In front of the tube is another rack, which moves a piece having an aperture for admitting a parallel passage of light, and one for holding an achromatic lens for convergent light. On the body of the instrument is a scale and a vernier, by which the thickness of specimens may be measured. The mirror is double—plane and concave—and may be given any position.

In the *Engineering and Mining Review* Prof. W. P. Blake describes a peculiar specimen of asphalt found in the Uintah Mountains, Utah. Its mineralogical properties are, "hardness, 2 to 2.5; gravity, 1.065 to 1.070; color, black, brilliant, and lustrous; streak and powder, a rich brown. It is a non-conductor of electricity, and is electrically excited by friction." It is easily fusible in the candle-flame, and burns with a brilliant flame. It is most readily dissolved in

the heavier and less volatile acids and fats, such as heavy, lubricating petroleum, warm oil of turpentine, etc. It is insoluble in ordinary alcohol. It is dissolved and becomes incorporated with melted wax, producing a mixture resembling "burnt wax" or ozokerite, with the latter of which this asphalt melts and unites. Prof. Blake says this kind of asphalt will probably be used in the arts, as a pigment, insulator and ingredient in lubricating, cereous and fatty mixtures.

Mr. Geo. F. Kunz, the writer of the above-mentioned article in the *Popular Science Monthly*, is also the author of a recent pamphlet on precious stones, being an abstract from the *Mineral Resources of the United States*. It is a very valuable and interesting brochure, as may be seen from the following quotations, regarding the diamonds of the United States: Early in 1855, a laborer in Manchester, Va., found a diamond in some earth he was digging. It was put into a furnace for melting iron, when it remained at red heat for two hours and twenty minutes, after which it was found uninjured, and brighter than ever. It was valued in Richmond at \$4,000. The cutting, which cost \$1,500, reduced the weight from $23\frac{3}{4}$ carats to $11\frac{1}{8}$ carats. Being an imperfect specimen, it is not worth more than \$400 to day. The first diamond found in North Carolina, was an octahedron, valued at \$100; another greenish in color, was found in 1852, in Lincoln Co.; another, a perfect crystal of white color was found in Mecklenburg Co. Other diamonds weighing from one-half a carat to over two carats are said to have been found in Burke Co.

In the current number of the *Popular Science Monthly* there is an interesting article by Geo. F. Kunz, on the famous Chalcedony Park or silicified forest, in Apache County, Arizona. This wonderful deposit consists of about a million tons of silicified trees, and covers a thousand acres. The writer supposes the manner of silicification to have been as follows: "The trees were overthrown, and covered with volcanic ashes and tufa; the heated silicified waters, either gushing from springs, or forced up by the violent volcanic action which felled the trees, percolated through the ashes, cooled on reaching the tree-level, and thus produced conditions favorable to silicification." The filtration through the tufa of waters from rains or springs would have assisted decomposition, and caused the silica to be set free. These waters, charged with silica in solution, penetrating into the cells of the wood, the cell-walls and fibres were replaced by jasper and agate, while transparent quartz filled the cells. The presence of oxides of iron and manganese in the waters of filtration produces a more rich and varied coloring in these silicified woods, than is found in those of any other part of the world. "The most remarkable feature of the park," says Mr. Kunz, "is the natural bridge of agatized wood, formed by a tree spanning a canyon forty-five feet in depth, and fifty-five in width. The tree is visible for a length of over one hundred feet. It averages three and a half feet in diameter, five feet at the thickest part, and three at the smallest." It is doubtful whether jade, jasper, or any of these ornamental stones have the richness of color, and the susceptibility of polish, which this agatized and jasperized wood possesses.

The November product of the great Venezuelan gold mine, *El Callao*, was \$211,458. The dividend for the month amounted to \$77,280, being 36½ per cent. of the product.

Proceedings of the Mineralogical Society for the Month of January.

The fifth annual meeting of the Mineralogical Society of the College of Ottawa was held on December 30th, 1885, when the election of officers took place, and the objects and prospects of the Society were discussed.

On January 5th, 1886, the regular work was resumed. Rev. Father Marsan, O.M.I., read a paper on "Silicates and their place in the mineral kingdom," in which he advocated the quite novel proposition that the silicates should be considered as a sub-kingdom. He treated the subject in a masterly manner, and in the discussion which followed disposed of the principal objections which were brought forward. Mr. W. Herckenrath read a paper on the "Mineralogy of Pliny," showing the great strides in advance made by the science since Pliny's time. Mr. D. A. Campbell gave a series of experiments illustrating the coloration of flame. Prof. Macoun, who was present at this meeting, highly praised the objects of the society and laid special stress on the importance of acquiring a knowledge of sciences by practical experiments such as he had witnessed.

On January 13th Mr. Wade Smith read an interesting paper on "sponges," and showed that though apparently quite foreign to mineralogy, they had in reality a close relation with that science. Rev. Bro. Maloney read a paper on the "Twelve Stones of the Essau." By the novel way in which he treated it he made a comparatively dry subject very interesting. Mr. C. C. Delaney followed with experiments showing the action of acids on limestone.

On February 13th Bro. Maloney continued his paper on the "Twelve Stones of the Essen." Mr. D. Phalen successfully performed several experiments illustrating the methods of testing for metals in solution. Rev. Prof. Marsan read an essay on the "lustre of minerals," which elicited an animated discussion.

BOOK NOTICES.

PRACTICAL AND ANALYTICAL CHEMISTRY: A complete course in Chemical Analysis. By Henry Trimble, Ph.G., Professor of Analytical Chemistry in the Philadelphia College of Pharmacy. P. Blakiston, Son & Co., Philadelphia.

This book supplies a want which has long been felt in institutions, where but a limited time can be devoted to the study of analytical chemistry. Most treatises on this subject are too comprehensive for an elementary course; and the result in many instances has been the elimination of analytical chemistry from the programmes of classical courses. Such a step is certainly to be regretted, as chemistry cannot be properly understood, nor students interested in it, when the subject is presented in its least practical aspect. A work was needed, elementary, yet sufficiently complete to give an exact notion of the science, and to enable the student to pursue afterward, if he so desired, a higher course of qualitative and quantitative analysis. This end has been secured by the present publication, which gives due prominence to every fundamental operation, and the most important confirmatory reactions. The whole work is written in a clear and concise style; tables are most conveniently placed at the end of each chapter, and the clear and beautiful type, distinct headings and neat illustrations, make it a very attractive text-book.

Practical Treatise on Hydraulic Mining in California, with Description of the Use and Construction of Ditches, Flumes, Wrought Iron Pipes and Dams; Flow of water on heavy grades and its Applicability, under high-pressure, to mining; by AEG. J. BOWIE, JR., Mining Engineer, New York; D. VAN NOSTRAND, 23 Murray street, 1885. pp. 313.

This handsomely printed and thoroughly illustrated work meets a want in an adequate manner and we welcome its publication. As a reference both for superintendents and engineers in charge of or undertaking hydraulic mining enterprises, it can but prove invaluable; supplying as it does, information based on the results of experience under almost every possible emergency in mining engineering, coupled with descriptions of the various mechanical appliances requisite under every possible condition. The tables which Mr. Bowie furnishes give the dimensions and cost of all the notable ditches and flumes in California; area and weight of wrought iron pipes generally employed; flow of water through pipes, with a mass of statistics regarding the operations of well known hydraulic mining operations.

The Determination of Rock-Forming Minerals by DR. EGGEN HESSACK, Private Docent in the University of Graz; translated by EUSTAS G. SMITH, Ph.D. Professor of Chemistry and Mineralogy of Beloit College, Wisconsin. New York: John Wiley and Sons, 1886.

This manual designed especially for the use of students, places before English readers a description of the optical and other physical properties of minerals in a condensed, yet exhaustive manner not found elsewhere, with the methods of investigation and rock-forming minerals; there is also given a copious table of the bibliography of the subject as well as explanation of the numerous cuts. This work may be had through the business office of the *Financial and Mining Record*, New York.

The Manufacture of Magnesium.—The problem of producing the semi-precious metals at a low price is now very actively considered in France, and in this direction small works for making magnesium have been established at Corbell. The most suitable lamp for burning wire of this metal is now the subject of investigation.

The Poetsch System.—The Poetsch system of freezing a water-bearing stratum for the purpose of sinking through it is to be applied in France to a shaft that has collapsed. This undertaking will be a peculiarly difficult one, and the result will be awaited with interest in all mining circles.

Russian Manganese Mines.—The Manganese mines of the Charapau District, 26 miles from the nearest railroad station, at Kwirila, Southern Russia, are growing in importance. In 1884, the output was 12,050 tons, and it is expected that during 1885 it will increase to 27,550 tons, of which 16,400 tons will be shipped from Batoum, and 11,150 tons from Poti. The bulk of the ore goes to England.

A productive Australian Gold Quartz District.—Charters Towers of Queensland, since the opening of its mines in 1872, has been steadily increasing in the yearly value of its quartz, crushing from 20,064 ounces of gold that year to 103,429 ounces for 1884, the value per ton of quartz crushed having been singularly uniform or about 1 ounce 13 dwts. 11 grains per ton.

NOVA SCOTIA.

Work at the Mount Uniacke mines progresses satisfactorily. The quartz carries gold in paying quantities, and a large amount of it can be mined at comparatively small cost from several lodes in the slate belt.

A good quality of fire-clay has been discovered at New Ross, also a manganese deposit of some extent. The distance from shipping point will, however, be a drawback to profitable mining.

Further work in the north cross-cut from the 150-foot level of the Coxheath copper mine has proved the existence of an additional vein four to five feet thick, the ore of which averages about 8 per cent copper.

During the year 1885 the Springhill mines raised 375,000 tons of coal. This is the largest output yet reached by any Nova Scotian mine, and it is anticipated that next year these figures will be greatly exceeded.

The Acadia and Vale Coal Companies of Pictou County have had meetings of their shareholders to complete the consolidation of all the companies operating in that district under one management.

The manganese deposit at Walton, owned by Messrs. Churchill, has proved to be more extensive than there was reason to expect. Some additional pockets have been met with which will doubtless yield a large quantity of high grade ore.

An unusually rich vein of gold-bearing quartz has recently been discovered on a property owned by Mr. C. B. Hilchey and others at Tangier, and the vein is now being thoroughly tested. Some of the quartz carries from 10 to 12 ounces of gold per ton, and it is expected the vein yield will be much above the average.

The exports of minerals from the province for the past two years have been, as nearly as can be at present estimated, as follows:

	1884.	1885.
Coal (sales) ..	1,261,650 tons	1,250,000 tons
Gold	16,069 oz.	20,000 oz.
Iron ore	54,885 tons	50,000 tons
Gypsum	111,068 "	90,000 "
Manganese	302 "	250 "
Antimony	600 "	800 "
Limestone	25,567 "	24,500 "
Building stone ..	780 "	800 "

MOOSE RIVER.—Twenty-five men are now mining in this district, most of whom are tributaries. The principal work is being done on what is known as the Little North Lead. The crushing material is composed of slate and small quartz, the thickness varying from 8 to 15 inches, and the yield 6 to 15 dwts. per ton. The new lead which was discovered last November is being worked by Mr. Toquoy with five men. Eighteen tons of quartz from this lead have been put through the crusher, yielding 17 ounces of gold. The ten-stamp mill, which is run by water power, is kept busy night and day, and even with this it is found difficult to crush all the quartz that is being taken out.—*Critic.*

The past year's production of gold in the province shows an increase over that of 1884, the output being estimated, approximately, at 20,000 ounces, as against 16,060 ounces for the preceding year.

The gradual but steady growth of the coal sales in Nova Scotia may be represented by decades of years as follows:

Years.	Tons.
1791—1800	51,048
1801—1810	70,452
1811—1820	91,527
1821—1830	140,820
1831—1840	839,981
1841—1850	1,533,718
1851—1860	2,399,819
1861—1870	4,927,319
1871—1880	7,377,428
1881—1885 (5 years)	6,094,366

NEW BRUNSWICK.

A deposit of *stibnite*, carrying sixty per cent. of *antimony*, has been discovered in Albert county, and miners will be at work on it in the spring to test its extent.

Discoveries of rich deposits of *manganese* have been made during the past few months in several localities in the province, and it is expected there will be a large production of this mineral during next summer.

It is probable that mining operations will be resumed in the spring at the manganese mine at Hopewell, Albert county. The mine has been inspected by a competent mining engineer, who has pronounced it capable of yielding a large annual output under intelligent and efficient management.

QUEBEC.

The Anglo-Canadian Asbestos Company are proceeding with active operations at their mine at Black Lake, and will not, hereafter, suspend work during the winter months as has been the custom.

The *Villeneuve* mica mine in the township of the same name, Ottawa county, is yielding a steady output of very fine mica. The mine is now fairly opened and is capable of producing a large annual supply.

Dr. James Reed has purchased the South Ham mines, Lake Nicolet, Wolfe county. This property includes asbestos, antimony, copper, iron and chromic iron deposits, and embraces an area of 2,000 acres.

The phosphate mines in the du Lièvre district and in Templeton are giving employment to a large force of miners and laborers, and ore is being brought to the surface in great abundance. The mines were never so productive as at the present time.

Good work has been accomplished during the past few months by the St. Onge Gold Mining Company at their mine on Slate Creek, Beauce. The drift from the bottom of the shaft is now in ground that carries coarse gold in paying quantity and is some feet above bed-rock. This company's prospects are very bright.

ONTARIO

Phosphate mining in the Kingston and Perth districts has not been engaged in during the past two years as actively as formerly; the attention of miners having been attracted to the larger deposits in the county of Ottawa.

The only mica mine now being worked in this province, that we know of, is near Sydenham, in the township of Loughborough, county of Addington. The mica is dark amber in color and is produced in quantity.

A new mining company composed of Toronto, London, Ont., and United States capitalists is being organized for the purpose of purchasing mining options on claims in the Thunder Bay district, and placing them on the market.

Ontario has sent to the Colonial and Indian Exhibition the largest and best exhibit and the greatest variety of iron ores that will be forwarded by any other province of the Dominion. It would be difficult to collect a better display of iron ores from any part of the world.

(Thunder Bay District.)

Some good silver ore has been taken from the *Porcupine* mine, and we hear that *Silver Creek* mine is producing a quantity of native and black silver.

The proposed line of the Lake Superior Mineral Railway runs through the silver district passing close to all the working mines on its way to the Huronian mine in the gold region.

The Beaver and Rabbit Mountain companies have given contracts for the erection of mills at their respective mines. It is expected that the mill will be in operation at the *Beaver* by the 1st July next.

The vein of the *Rabbit Mountain* is said to be dipping, with a strong incline, under the *Rabbit Mountain Junior* property, while the vein of the latter dips towards the former property. It is a question which will carry the other when the two veins meet.

Within twenty-five miles of Port Arthur there are five working silver mines, viz.: the *Rabbit Mountain*, *Beaver*, *Silver Creek*, *Twin City* and *Rabbit Mountain Junior*. They are within three miles of each other and are connected with Port Arthur by wagon and winter sleigh roads.

Gold and silver were discovered last summer on the east shore of Lake Nepigon. A winter road has been made from Nepigon Station on the line of the C. P. R., a distance of 15 miles, to the location, and miners are now at work proving the discoveries. A car load of ore will be shipped to New York for a practical mill test.

BRITISH COLUMBIA.

About four tons of quartz from Ireland mountain, Cariboo district, have been crushed and found to yield \$20 per ton.

The total exports of gold from the province for the year 1885 amounted to \$594,782.52 as reported by Wells, Fargo & Co.

It is expected there will be considerable squabbling over claims on Granite Creek and tributaries in the spring if they should prove valuable, as no doubt many are held illegally.

Work was shut down on Granite Creek towards the end of November. Extensive preparations have been going on during the winter for spring work, which will be resumed about the end of the present month and continued until the June or July freshets set in. When the water again subsides there will be no interruption for the balance of the year.

If capital were forthcoming to develop the quartz ledges which exist in Kootenay district there is little doubt as to the result, the richness of these ledges being well known.

The Quesnelle Quartz Mining Company are doing good work in Cariboo. They have twenty men employed, including an expert and many practical quartz miners.

The total yield of the Cariboo district for the year 1885 is in the neighborhood of \$350,000. It has been said by some that Cariboo is played out. Others, however, are of opinion that it has not yet seen its palmiest days.

Upwards of \$100,000 worth of gold has been accounted for as having been taken from Granite Creek the past season. There are now wintered in the district about 800 white miners and 300 to 400 Chinamen, and there is no poverty among them.

At Lorne Creek authentic reports show that the yield for 1885 has been considerably less than for the previous year. Gold mining was first started in 1884 on Lorne Creek, which is a tributary to the Skeena River, and the gold taken out of it is valued at \$17 per ounce.

Fresh discoveries have been made on what is known as the South Fork of Granite Creek and in some smaller creeks. Champion Creek is also a recent discovery, emptying into the Talaquen river, about twenty miles above the mouth of Granite Creek. Several claims have been located on it and the prospects for gold are very promising.

The following is the total output of coal from the Wellington and Vancouver mines for the year 1885:

Wellington mines (tons)	220,000
Vancouver " "	137,548
	357,548

These two mines furnish employment for over a thousand men.

UNITED STATES.

The production of copper in the United States in 1885 reached about 155,000,000 pounds of fine copper, as against 145,000,000 pounds in 1884.

The product of copper ingot from the Calumet and Hecla mine from 1875 to 1883, both years inclusive, was not more than 4.80 per cent. of the ore mined.

A short time ago a shaft was sunk to a depth of 1,100 feet in Livingston County, N.Y., when a vein of pure rock salt was struck 18 feet in thickness. The salt produced from the seam is 99.37 per cent. of rich chloride of sodium.

The gold bullion produced by the mines of the Plymouth Consolidated Gold Mining Company, California, for the year 1885, was \$880,527.44; operating expenses amounted to \$319,750.91, leaving a profit of \$560,776.53.

It is now an established fact that the Calumet and Hecla Copper Company is to have smelting works at Lake Linden. The new works will be erected by the Detroit and Lake Superior Copper Company, for the smelting of Calumet mineral.

Welland Canal Enlargement.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for the Welland Canal," will be received at this Office, from mechanical, skilled practical contractors, until the arrival of the Eastern and Western mails on TUESDAY, the NINTH day of MARCH next, for raising the walls of the locks, weirs, &c., and increasing the height of the banks of that part of the Welland Canal between Port Dalhousie and Thorold.

The works throughout will be given in sections.

A map showing the different places together with plans and descriptive specifications, can be seen at this office on and after Tuesday, the 23rd February instant, where printed forms of tender can be obtained. A like class of information relative to the works will be supplied at the Resident Engineer's Office, Thorold.

Parties tendering are requested to examine the locality and bear in mind that the season and circumstances under which the works have to be done, render some of them of an exceptional nature.

Tenders will not be considered unless made strictly in accordance with printed forms and, in the case of firms, except there are attached the actual signatures, the nature of the occupation, and place of residence of each member of the same; and further a bank deposit receipt for the sum of Two Thousand Dollars or more—according to the extent of the work on the section—must accompany the respective tenders, which sum shall be forfeited if the party tendering declines entering into a contract for the works at the rates or prices stated in the offer submitted. The amount required in each case will be stated on the form of tender.

The deposit receipts thus sent in will be returned to the respective parties whose tenders are not accepted.

This Department does not however, bind itself to accept the lowest or any tender.

By order
A. P. BRADLEY,
Secretary.

Copies on Tracing Linen 1.50

ON SALE AT THE
OFFICE OF THE "MINING REVIEW"
OTTAWA

AND THE
GEORGE BISHOP ENGRAVING & PRINTING CO.
169 St. James St., Montreal.

FOR SALE

Valuable Phosphate and Farming Property,

In the Township of Templeton, County of Ottawa, Province of Quebec, adjacent to the celebrated phosphate mines of Melanin and Blackburn, Jackson Rae, J. H. Post, and others, consisting of

LOT 14, RANGE 13 AND N^o 14, RANGE 9,
CONTAINING 300 ACRES.

Dwelling-house, Barns, Stables and Out-houses, in good order, on the property, in proximity to a good phosphate opening from which several tons of high-grade phosphate have been raised, and where mining operations can be at once started.

The property has been partially prospected and several promising out-croppings of phosphate have been exposed. It has been pronounced a valuable phosphate location by miners working in the vicinity, and satisfactory reasons can be given for offering it for sale.

The owners, Messrs. Pearson, who hold a clear title to the lots, will sell them in fee simple, or the mining rights only.

Cost of transportation from the property to point of shipment will not exceed \$2 per ton.

For terms and full information apply on the premises, or to

THE POSTMASTER,
East Templeton, Pro. Que., Canada.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned, and endorsed "Tenders for Ice, Public Buildings," will be received at this office until Thursday, the 24th of February next for supplying the ice required during the season of 1886 for the Public Buildings, Ottawa.

Sealed tenders, endorsed "Tenders for Ice, Government House, &c.," will also be received at the same time for filling the ice house at the Rideau Canal Basin, Ottawa, and that at Government House.

Tenders to state price per block of the following dimensions, viz:—3ft. by 1ft. by 1ft., which price must include cost of packing and of the saw-dust required for that purpose.

The ice to be measured before being packed in the ice house and payment to be made accordingly.

N. B.—The ice must be taken from the Ottawa River, above the Chaudiere Falls.

By order,
A. GOBEL,
Secretary.

Department of Public Works,
Ottawa, 20th Jan., 1886.

GRAND COLONIAL

Exhibition in London, Eng.

1886.

FIFTY-FOUR THOUSAND FEET RESERVED
FOR CANADA.

First Royal Exhibition Commission Since 1862.

THE Colonial and Indian Exhibition to be held in London, England, commencing May 1st, 1886, is intended to be on a scale of great magnitude, having for object to mark an epoch in the relations of the parts of the British Empire with each other.

In order to give becoming significance to the event, a Royal Commission is issued for the holding of this Exhibition, for the first time since 1862; and His Royal Highness the Prince of Wales has been appointed President by Her Majesty.

The very large space of 14,000 square feet has been allotted to the Dominion of Canada by command of the President, His Royal Highness.

This Exhibition is to be purely Colonial and Indian, and no competition from the United Kingdom or from foreign nations will be permitted, the object being to exhibit to the world at large what the Colonies can do.

The grandest opportunity ever offered to Canada is thus afforded to show the distinguished place she occupies, by the progress she has made in Agriculture, in Horticulture, in the Industrial and Fine Arts, in the Manufacturing Industries, in the Newest Improvements in Manufacturing Machinery and Implements, in Public Works by Models and Designs; also in an adequate display of her vast resources in the Fisheries and in Forest and Mineral wealth, and also in Shipping.

All Canadians of all parties and classes are invited to come forward and vie with each other in endeavoring on this great occasion to put Canada in her true place as the premier colony of the British Empire, and to establish her proper position before the world.

Every farmer, every producer, and every manufacturer, has in every assisting, it having been already demonstrated that the extension of trade always follows such efforts.

By order,
JOHN LOWE,
Sec. of the Dept. of Agriculture.
Ottawa, 1st Sept., 1885

Notice to Contractor

SEALED Tenders addressed to the undersigned, and endorsed "Tender for Infantry School, London," will be received at this office on MONDAY, 29th proximo, the several works required in the erection and completion of

Infantry School, London, Or

Plans and specification can be seen at the Department of Public Works, Ottawa, at the office of Messrs. Durand & Moore, Architects, London, Ont., on and after Monday, 15th proximo.

Persons tendering are notified that tenders will not be considered unless made on printed forms supplied, and signed with actual signatures.

Each tender must be accompanied by an accepted bank cheque, made payable to the order of the Honourable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If a tender is not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

A. GOBEIL,
Secretary

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Early in the present month an influential deputation, composed of representative men, waited on the Minister of the Interior to call his attention to the dissatisfaction that prevails among those who are interested in mining in Canada by reason of the past indifference of the Geological Survey to the collection of statistics and information connected with our mines and minerals, and urged upon him the importance and necessity of establishing a Bureau of Mines in connection with the Survey. A short account of what was said and done by the deputation is reported in another column, and it will be seen by reference to the list of names that the gentlemen who have taken up the subject are for the most part members of Parliament representing constituencies largely interested in mining, and all of them, twenty in number, are directly or indirectly interested in the development of Canada's mining industries. This is not the first time that the central government has been requested to establish a Bureau of Mines and Mineral Statistics, nor is it the first time that its attention has been called to the lack of some such means of collecting and classifying facts as to the sites and yield of our economic minerals. What is desirable is a complete series of statistics relating to the minerals of the Dominion, issued at regular intervals and corrected and enlarged as new information is obtained. It is worthy of note that at the meeting in Montreal in 1884 of the British Association, the President stated

that the collection of statistics was of very great importance, and he thought it would be a good thing if the Canadian Government would take the matter into their serious consideration and find a way to the establishment of a Bureau for the purpose.

MR. CLEMENT Le NEVE FOSTER, of Wales, at the meeting of the British Association above referred to, said that the system in vogue in England for the collection of mineral statistics was the result of a meeting of that Association, and he considered that their visit to Canada will not have been thrown away if the only outcome of it is to be the establishment of a system for the collection of statistics of the mining interests throughout the Dominion. He suggested that a similar system to that in England might be adopted by the Canadian Government, and stated that at the last meeting of the inspectors of mines, in England, a table of the mineral statistics of the British Colonies was compiled for the Home Office, and great difficulty was experienced in collecting any statistics of the Canadian minerals.

Surely it is right that a country with so much wealth of the mine such as Canada possesses should have a proper system for the collection of its mineral statistics, and it is fervently hoped that a suggestion on that head, coming with all the weight of the economic section of the British Association, shall not have been made in vain. Any suggestion supported by such authority should not be without its influence on our central government, and now that this need has received the confirmation of the representatives of our mining communities, and has been brought by them so forcibly to the notice of the Minister of the Interior, it is expected that through him it will receive the early attention of the Government, and that a Bureau of Mines and Mineral Statistics will shortly be announced as a recognized and permanent feature of the Geological Survey of Canada.

Some weeks ago there appeared in one of the leading Ontario morning papers the following paragraph, which should be of especial interest to the mining community:

"WHY PROF. SELWYN IS DISLIKED."

"Professor Selwyn, in charge of the Geological Museum, will leave on Tuesday next for England to make preliminary arrangements for Canada's geological exhibit. From what can be learned from reports made against Prof. Selwyn, it would appear they have been prompted by those who, having personal interests to serve, were thwarted by this officer. During the coming session of Parliament some startling revelations are likely to be made, in which it will be shown that several individuals occupying seats in the House of Commons have endeavoured to tempt Prof. Selwyn with bribes to report favorably on mineral properties they held, and which they wished to develop. Hence the attacks on the Professor."

This appears to have been inspired on good authority and has not been contradicted. It is a serious charge, insidiously and vindictively made, and the paragraph has probably escaped the notice of those who would be most interested in reading it.

In our last issue, referring to the cause of the strike at the Springhill coal mines, Nova Scotia, it was put down as owing to the unsafe condition of part of the workings. We are informed that this was not the case, but that the trouble arose through the alleged harder quality of the coal in certain working places. These mines have hitherto been noted for the care and attention given to the safety of the workmen, a praiseworthy character, which has been frequently commented on by visitors, and notably on the occasion of a visit recently paid to them by an English Inspector of mines, who remarked that the occupation of mine inspectors would be dispensed with if all English mines were conducted with equal care.

Elsewhere we give a short account of what transpired at the meeting in Hull, called for the purpose of pressing the Gatineau Valley Railway Company to resume the work of construction and to push it vigorously with a view to the early completion of the road. If the President's promises and assurances are to be realized it will be necessary that the Quebec Government proceed at once to locate the land grant, on which, according to Mr. Mackintosh's statements, depends the consummation of his negotiations for the building of the road. The Gatineau Valley Railway would be an important factor in opening up and stimulating great mining industries in the county of Ottawa, and we earnestly hope that the Government will, so far as it lies within their power, remove every obstacle that serves as an excuse for the incompletion of the road.

The advisability of grinding Canadian phosphate rock and shipping it in a pulverized state has for some time occupied the attention of mine owners, and the experiment is about to be put to a practical test by the Portland, P.Q., Phosphate Mining and Milling Company. This company have erected and furnished a mill at the Basin du Lièvre, near Buckingham, and will grind and ship a large quantity of phosphate during the coming season. The mill is very conveniently situated for shipping as regards railway and water communication, and the water power for driving purposes is unlimited. The Portland, P.Q. M. & M. Co. have everything in their favour, and if this branch of our phosphate industry is practicable from a commercial point of view, and can be profitably carried on under any circumstances, their enterprise should and no doubt will be rewarded by successful results.

If this first attempt to establish a separate branch to our phosphate industry proves a success it will give an impetus to mining in the district and will be an incentive to others to erect mills for crushing and grinding phosphate rock. We are not informed as to what description of mill the Portland company has procured, but we have seen samples of the rock it has ground to an impalpable powder, from which we judge

that it does good work. Our attention has been directed recently to the many advantages the "Sturtevant" mill possesses for this particular class of work. It has been designed for crushing and grinding phosphate, emery and all hard and refractory ores, and practical mill superintendents who have used it on all descriptions of ores have attested to its unquestionable merits. The "Sturtevant" is a crusher and stamp-mill combined, and it is of extremely simple construction. It is arranged to grind to any fineness desired, from one and one-half inch mesh to an *impalpable powder*, and is so compact in its construction that it occupies less space than any other mill we know of having the same capacity. It is a powerful, efficient and durable machine, and can be operated with great economy, which, in addition to its simplicity, execution and capacity, should recommend it to people who are engaged in crushing and grinding ores. We would advise those who contemplate engaging in grinding phosphate to examine the "Sturtevant" mill, as we deem it a very suitable machine for this purpose.

We are indebted to Mr. Chas. W. Willimott, Curator of the Geological Museum, for a copy of his paper on the *Minerals of the Ottawa District*, read before the Ottawa Field Naturalists' club. In dealing with this interesting subject, Mr. Willimott confines himself to the three neighbouring townships, Templeton, Hull and Wakefield, as his own observations had extended only over that portion of the county of Ottawa. He enumerates the various minerals that occur within that area, and gives an intelligent, general outline of the more important characters of each, dwelling more particularly on the features of the deposits of Apatite, Iron and Graphite. Mr. Willimott informs us that about sixty minerals are known to occur in the three townships referred to, many of which are unrivalled in the Dominion, and adds that it is doubtful if the same extent of country elsewhere in Canada can claim one-half that number.

THE PHOSPHATE TRADE.

There is no disposition on the part of mine owners to check the output of their mines—on the contrary, they are working their properties to their utmost capacity, and many thousands of tons of ore are now awaiting transportation. The present appearance of the mines and the activity which has characterized operations since the close of the shipping season of 1885 justifies us in predicting, as we did in our last month's issue, that the quantity of phosphate that will go forward this year will be several thousand tons in excess of the shipments of any former year since this industry was inaugurated in Canada. The accumulation of ore at the various mines also indicates that this will be the case, and close inspection of the contents of the orebins leads to the conviction that this year's shipments will be of superior grade, and will average, as they did for 1885, over 80 per cent. Careful dressing of the ore is a

sine qua non to the success of Canadian phosphate mining, and mine owners having learned by experience how necessary such precaution is, if they wish to obtain high prices for their output, it is not likely they will retrograde and become careless on this essential point.

The principal contributors to the general output of Ottawa county for this year will be The Phosphate of Lime company, the Union Phosphate company, the Dominion Phosphate company, the Ottawa Phosphate company, W. A. Allan, Ottawa, the Du Lièvre River Phosphate company, the Glasgow-Canadian Phosphate company, and Messrs. McLaren & Blackburn. Of these it is not improbable that the Dominion Phosphate company will be the heaviest producers, while all the others will undoubtedly send forward large shipments. Another powerful corporation, the Anglo-Canadian Phosphate Company, will engage in active operations in Ottawa county and in the Perth district early in the spring, and will help to swell the general output. This company has been recently organized in England under most favourable auspices, and will henceforth engage extensively in phosphate mining in Canada. Every day, we might say, brings us fresh evidence of the expansion of this important industry, and a few remarks from us on

THE FUTURE OF CANADIAN PHOSPHATE

may interest our readers.

When Canadian phosphate first entered the English market, it encountered much disfavor and some serious objections. Its hardness made it difficult to grind; the fluorine that it contained gave out offensive odors and injured the workmen's throats; after being made soluble by sulphuric acid it became partially insoluble again, or in technical phrase "went back;" in fact every manufacturer had his pet grievance against it, and for some years it was difficult of sale. Its high quality and comparative cheapness after awhile enforced attention, and the assurance of steady supplies, owing to enlarged working and the low rates of freight obtainable by vessels that required ballast under their deal cargoes, made it an object for manufacturers to overcome the difficulties connected with its use. The result is that although the shipments for the past year were the largest ever known, a month after the season had closed there was not a ton of Canadian phosphate to be had in England in answer to the demands of buyers, the whole having gone at once into the hands of consumers. The largest manufacturer in England states that he now uses as much Canadian as Carolina rock. He not only uses it largely with Belgian and other low grade phosphates to serve as an enricher, but he makes a high class superphosphate from Canadian rock alone. His chemist is said to have a "wrinkle" by which he gets better results than some others obtain and his success leads to further experiment.

In Germany Canadian phosphate has likewise been winning its way and all the 80 per cent. phosphate that Canada can produce with the present facilities can be readily sold in that market.

In spite of the favor it has gained, prices are exceptionally low; this is partly due to the competition of Curacao and Aruba phosphates from the West Indies, but chiefly is owing to the intense agricultural depression that now prevails. Much land has been thrown out of

cultivation and many farmers are too poor or too discouraged to buy fertilizers. This leads the numerous manure manufacturers into sharp competition to dispose of their products; the prices they sell at leave no profit and their efforts become intensified in the direction of cheapening the raw material. It is, however, significant that the Chemical Manure Manufacturers' Association, which is a combination of all the leading manure makers in Great Britain, at its annual meeting proposed combined action, not to buy cheaper, but "to keep phosphates at their present low level," showing that in their opinion bottom prices for raw material had been reached.

In Europe Canadian phosphate must always meet with strong competition, but there is a hitherto neglected field where it is destined to reign without a rival. The report of the National Fertilizer Association of the United States shows that over a million tons of fertilizers were made in the United States in the past year and that the output is increasing at the rate of 100,000 tons per annum. About three-fourths of the whole was used in the States adjoining the Carolina phosphate beds, while but little was used in the extreme Northern States, although the lands there equally demand it, and almost none was used in Canada in spite of the utter impoverishment of the once prolific wheat fields of Quebec. As knowledge of scientific farming extends, artificial fertilizers will be largely used in these sections and Canadian phosphate is the natural source of supply. By the return grain vessels from Kingston phosphate can be sent through the great lakes to the northern cities of the United States for a freight of \$1.50 to \$2 per ton, whereas the Carolina phosphate must pay \$5 to \$6 per ton by rail to these points, besides which the Carolina contains only about 55 per cent. of phosphate of lime as against 80 per cent. in Canadian phosphate.

The establishment of fertilizer works in Canada and the Northern States will doubtless be speedily accomplished, and a large market must open for Canadian phosphate in addition to the expanding demand in Europe. These facts and considerations show that a good future awaits this industry, and as the output of Carolina phosphate has grown from 20,000 tons in 1870 to over 430,000 tons in 1885 with an ever widening market, so we may expect a similar increase in the output of Canadian phosphate.

Phosphate Quotations.

The most recent advices from abroad report the phosphate market sluggish, although 1s. $\frac{1}{2}$ d. is freely offered for future delivery for 80 per cent, with *one fifth of a penny rise*. The present condition of the phosphate market is owing to the depression in all branches of trade, but it is expected to be more buoyant after the opening of navigation, and when shipments begin to arrive at Liverpool, London and European ports.

Large Phosphate Contracts.

Two weeks ago we reported sales of Canadian phosphate for spring shipment, and we have now to note contracts to the extent of 8,000 tons for shipment at this port (Montreal) during the coming season. It is understood that these large contracts have been made by the Dominion Phosphate Company, through Messrs. Lomer, Rohr, & Co., mostly for Continental ports. The prices are strictly private, but it is believed that the sales of Canadian apatite mentioned in the *Trade Bulletin* of March 5th had reference

to a portion of the above contracts, which was on a basis of 13½d per unit with a fifth of a penny rise for 80 per cent. rock delivered at Hamburg. The shipments of the above phosphate company last year were about 3,000 tons, so that the output this year will show a remarkable increase in one mining company alone.—*Trade Bulletin.*

Anglo-Canadian Phosphate Company, (Limited).

We are pleased to announce the organization of this corporation and to acknowledge the receipt of the company's prospectus. The Anglo-Canadian Phosphate Company has been formed for the purpose of consolidating Captain R. C. Adams' interests in phosphate lands in the Perth district, with those of some Englishmen owning phosphate locations in the same neighbourhood, and the entire interests of the Lièvre River Land and Phosphate Company, whose properties lie in the Lièvre district of the county of Ottawa. The company has been incorporated under the Companies Acts of Great Britain, 1862 to 1883, with a capital of £65,000 (about \$325,000), in 6,500 shares of £10 each, and is composed of wealthy and influential English capitalists and merchants of Montreal, as follows:—

Directors.

SIR JOHN MORRIS, Wolverhampton.
JOSEPH THOMPSON, Esq., Manchester.
WILLIAM CROSFIELD, Esq., Liverpool.
P. MOIR CRANE, Esq., Manchester.
R. A. JOB, Esq., Liverpool.
W. T. COSTIGAN, Esq., Montreal.
CAPT. ROBERT C. ADAMS, Montreal.

Bankers.

THE CITY BANK, London, E.C.,

Solicitors.

Messrs. LAYTON & STEEL, Liverpool.

Auditors.

Messrs. LEWIS & MOUNSEY, Liverpool.

Secretary and Agent in England.

BRAINERD RADCLIFFE, Esq., Liverpool.

Offices.

3 Chapel Street, Liverpool.

Much credit is due to Captain Adams who has been most active in organizing this powerful company. He has been one of Canada's most enterprising phosphate miners for the past ten years, and although he has been deservedly successful since he first engaged in the industry he has always been of the opinion that operations conducted on a large scale would be more profitable. The Anglo-Canadian company will shortly proceed to do extensive work in the Perth and Lièvre districts, where Captain Adams and the Lièvre River L. & P. company have been merely prospecting awaiting this enlargement. We have no doubt this new company will prove the theory of extensive operations to be a correct one and we wish them every success.

BRITISH AND CANADIAN MINING AND MICA COMPANY.

Application has been made by this company for Letters Patent of Incorporation, under the Canada Joint Stock Companies Act, with power to mine for mica, feldspar, asbestos, phosphate of lime, plumbago, iron and other metals and minerals in the Province of Quebec. The incorporators are Messrs. W. A. Allan, L. H. Shirley, and B. H. Buckstone, London, England. The company have secured some valuable mining locations, and will engage in active operations without loss of time.

The Phosphate Mines of Canada.

BY DR. SMALL.

(In the Mining Journal, London, England).

This is a common mineral in the limestones of the Laurentian rock, sometimes disseminated in minute blue or green crystals, and at other times so abundant as to make up a great proportion of the rock, and in some cases to form beds of a nearly pure crystalline apatite. Of late years the increasing demand for phosphates as fertilisers of the soil has drawn attention to the use of this mineral in a prepared form, and the large supplies existing in Canada are now receiving considerable attention. In the "Geology of Canada" the apatite deposits of the district lying back of Kingston are described as beds. Dr. Sterry Hunt, in his early reports of 1863-66, when attention was first called to the existence of this mineral in Canada, stated that though it did occasionally occur in beds, the workable deposits were "with few, if any, exceptions confined to the limestones." His reasons for regarding most of the deposits as concretionary veinstones depended upon such facts as "banded structure," the "presence of drusy cavities," and the rounded forms of certain crystals, indicating, as he styles it, "a process of partial solution succeeding that of deposition." Professor Harrington says in his report on the apatite district of Ottawa, as a rule the apatite-bearing veins are characterised rather by "a want of regularity or order in the arrangement of their constituents than by any degree of symmetry." Instances do occur, however, where they show a banded structure. Veins with sharply defined walls, as in metaliferous lodes, are rarely seen, the vein and counter rock merging into each other. Dana says such a blending of a vein with the walls is a natural result when its formation in a fissure takes place at a high temperature during the crystallization of the containing rock. Dr. Sterry Hunt regards many of the apatite veins as fissures or cavities which have been filled by the deposition of materials derived from the adjacent strata. In reply to the question so often put "what is the nature of phosphates, and how have they been formed?" it may not be out of place to mention the two sources of supply given by Dr. Dawson, an eminent authority on this point—the concentrated deposits of phosphatic matter known as guanos, which form two subdivisions, nitrogenous and phosphatic, such as the bird excrements occurring only in the exceptionally dry climates of the South American coast, and the crystalline deposits of Canada, Norway, and elsewhere. In the nitrogenous phosphates the organic matter converted by decomposition into ammonia salts remain as part of the mass. In phosphate guanos the rain has removed the soluble ammonia salts, but has left the phosphatic material. This class of guanos is met with in the West India Islands, and Dr. Dawson thinks the deposits in the South of France known as Bordeaux phosphate are of a similar nature, and may be also traceable to mussel mud, or the accumulations in shallow tidal estuaries of molluscs and other marine organisms. Coprolite beds, such as those of the eastern countries of England and of South Carolina, have resulted from concretionary action, the slow process of drawing together of like particles in the mass, fragments of shells, bones, &c., serving as a nucleus, and when the material is abundant such concretions coalesce, and form layers. The word coprolite, however, should be confined to the fossil excrements existing in abundance in certain localities on the eastern

coast of England of various animals, notably the saurian monsters of the antediluvian shores. In the Laurentian rocks of Canada, says Dr. Dawson, are a great volume of sediments deposited in the earliest ocean of which we have any trace, but which originally, resembling those of later seas, have been so completely altered that their materials have entered into new combinations, and have become entirely crystalline, resembling now the original deposits as little as do the crude ingredients of glass the finished product. There can be no doubt of the original sedimentary origin of these Laurentian rocks, mussel muds, sands and coprolite layers being changed by volcanic or igneous action to wholly crystalline rocks. To substantiate this it is shown how limestones thus acted on would assume a crystalline character as marbles, beds of a peaty or coaly nature would pass into crystalline carbon or graphite, and phosphatic layers would appear as crystalline calcic phosphate or apatite. All these substances are found in close contiguity in the Ottawa district, an evidence pointing directly to the correctness of the theory. The greatly disturbed character of the Laurentian rocks explains the great irregularity of the apatite deposits, layers and veins, which may, before the great folding and kneading together of these rocks, have possessed regularity and uniformity, but through excessive disturbance have been dislocated in every sense, leading to the production of large pockets and irregular masses connected only by narrow and twisted seams; they may even appear to occupy completely isolated portions. The broad zones containing workable deposits of apatite and intervening belts offering little encouragement for the miners are shown in a map published by the late Mr. Vennor in the Geological Survey Report of 1876-77, and a reliable clue is thus given to prospectors where to direct their researches.

Mr. Torrance, lately on the Geological staff, states that the heaviest apatite deposits lie along the valley of the Lièvre, but proceeding eastward or westward from this river the deposits become more and more mixed with calcite, until they finally cease to be profitable for mining. The various forms in which apatite presents itself in the Ottawa district are as crystals sometimes of large dimensions, in masses varying from compact to coarse granular, in strata of a lamellar texture, and in a friable variety which is abundant, known as "sugar phosphate." The latter on account of its friability is much easier to grind than the compact masses, but is more apt to undergo loss in handling. This could be obviated by barrelling, or by putting it up in coarse bags. The color varies, being various shades of green, blue, red and brown of different shades, yellow and white. Hoffman, the analyst of the Geological Survey, says that from its usual high percentage of phosphate of lime, Canadian apatite may be regarded as a most eligible material for the manufacture of superphosphate. Generally speaking it contains only small quantities of oxide of iron.

ONTARIO.—In his report on the county of Hastings Mr. Vennor, of the Geological Survey staff, in 1871, called attention to large workable deposits of phosphate existing there that had been quarried on and off for over 20 years, which he denominated as "the North Burgess Phosphate Basin," and "the Bedford, Storrington and Loughboro Basin." The former of these extends through the townships of North Burgess, South Crosby, and Bedford, and was found to have a thickness of from 2,600 to 3,000 feet, forming a belt or zone running from the north-east to the south-west corner of Burgess, south-westward through Crosby; the latter runs

through the south-east corner of Bedford township and on through the townships of Storrington and Loughboro. The width of basin is about 6 or 7 miles, and narrows in places to half that width. The available deposits of phosphate appear to occur towards its outer side. The richest deposits of this mineral occur in the townships of North Burgess, where a large number of phosphate mines, or "openings," are worked with very fair returns. Of these, 145 in number, are described in Mr. Vennor's report. (Geological Survey, 1873-74). Phosphate is met with, more or less, all through the district lying north of Kingston and Belleville, and analyses made from specimens taken in different localities gave on an average 88 per cent. of phosphate of lime.

QUEBEC.—The Laurentian mountains of the province of Quebec seem to offer greater advantages than elsewhere for mining this mineral, especially in the Ottawa district of the province of Quebec. Here, however, this industry is of comparatively recent date, and is carried on for the most part in the townships of Buckingham, Templeton, Portland, Hull and Wakefield, in the county of Ottawa. There is no doubt that this mineral is to be met with in a much wider district than the townships above mentioned; but mining it has so far been confined to these localities running in a north-easterly direction from the Blanche river across the Lièvre river into the adjoining country east of the latter. This belt is very productive, yielding a very fine quality of apatite.

(To be Continued.)

COLONIAL AND INDIAN EXHIBITION.

The Government of Nova Scotia by special arrangement with Sir Charles Tupper, have secured the privilege of exhibiting a collection of the minerals of that Province *en bloc*. This will show the mineral wealth of Nova Scotia in a much more satisfactory manner than the more scientific but less practical arrangement adopted by Dr. Selwyn for the general exhibit of the Geological Survey. The exhibit of the Provincial Government will be strong in coal and iron, and some fine gold samples will be shown, but as the work of collecting was not begun until the last of December, it is far short of a complete representation. There will be over one hundred exhibits, all of which have been shipped. The annual report of the inspector of mines will contain a short account of the minerals of Nova Scotia, in addition to the annual summary of mining progress, and an extra edition will be sent to London for distribution at the exhibition.

Among the most important and interesting exhibits that have been forwarded from Canada to the C. & I. E., went from Ottawa city. The Canadian Granite Company have sent many exceedingly handsome designs in serpentine, granite and marble, as well as specimens of the stone in the rough from their quarries.

The Dominion Plumbago Company have forwarded a very creditable exhibit, consisting of prepared stock for pencils, lubricating, electrotyping, crucibles, stove polish, foundry facings, refractory goods, pencils in the various stages of manufacture from the lowest to the highest grades—also specimens of crude graphite, including one solid block, weighing 3000 pounds.

Mr. W. A. Allan has contributed a very valuable collection of apatite crystals, one weighing upwards of 500 pounds; his exhibits of mica will not be excelled, as regards its lustre and transparency, its refractory nature or the size of the plates, some of which measure 13x8 inches; while his contribution of gold from his

mines at St. George East, Beauce County, will surprise visitors at the exhibition. It consists of a large number of beautiful nuggets, weighing from several pennyweight up to 1½ ounce, a quantity of coarse gold, and a fine display of gold dust.

AN INFLUENTIAL DEPUTATION.

**Representative Men Interested in Mining
Wait Upon the Minister of the Interior.**

THEY WANT A BUREAU OF MINING AND MINERALOGY ESTABLISHED

For a long time it has been felt by those immediately concerned in the development of our mineral resources that insufficient attention has been given in the past to the collection of statistical and other information relating to these resources and the mining industries of Canada. The eminent geologists, mineralogists and mining engineers, who visited us in 1884, as members of the British Association for the Advancement of Science, expressed surprise and regret that some such desirable records did not exist, and strongly urged that prompt steps should be taken towards supplying this want.

This has been felt to be a well-merited reproach, and prompted by a desire to see it removed a large and influential deputation, composed of representative gentlemen from the mining sections of Canada, from the Atlantic to the Pacific, waited on the Minister of the Interior on the morning of the 4th inst. for the purpose of pointing out to him the necessity of establishing a mining and mineralogical department in connection with the Geological Survey for the purpose of collecting and compiling, under an organized system, information and statistics regarding the important mineral deposits and mining in Canada. It was clearly shown how valuable public records of this nature would be to every one interested in the mineral development of the country, to whom the same should be always available. The members of the deputation, numbering 21 in all, were a unit on all points raised, and the Minister, who is ever ready to listen to and act on the suggestions of practical men, gave assurance that the matter would receive careful consideration, and practically concurred with the deputation on the essential points that were brought up in the course of discussion.

The following gentlemen composed the deputation and left with the Minister the subjoined memo., on which they desired that prompt action should be taken:—S. J. Dawson, M.P., Algoma; R. N. Hall, M.P., Sherbrooke; Jas. Reid, M.P., Cariboo, B.C.; C. H. Tupper, M.P., Pictou; Dr. G. T. Orton, M.P., Wellington, E.R.; C. J. Townsend, M.P., Cumberland; C. A. Everett, M.P., St. John; John McDougall, M.P., Pictou; H. F. McDougall, Cape Breton; T. S. Spronle, M.P., Grey, E.R.; Wm. McCraney, M.P., Halton; B. Allen, M.P., Grey, N.R.; H. Cameron, M.P., Inverness; H. N. Paint, M.P., Richmond, N.S.; C. E. Kaulbach, M.P., Lunenburg; Murray Dodd, M.P., Cape Breton; M. B. Daly, M.P., Halifax; R. G. Leckie, Spring Hill, N.S.; W. Hamilton Merritt, M.E., Toronto; David McKean, Manager Glace Bay Mines; E. Grant Powell, Ottawa.

"Whereas, it is believed that the information and statistics regarding mining and mineral developments in Canada furnished by the Dominion Government are not in keeping with the desire of those interested in such developments, and are neither sufficient nor accessible enough to supply the public with full, authentic and prompt information on these subjects; we do, therefore, wish to respectfully bring to the attention of the

Government the following desires of a section of our community:—

"1. To have full and reliable information of the mining and mineral developments, and statistics connected therewith, for the whole Dominion, published each year, as soon after the end of the year as possible.

"2. To have a medium through which information relating to our miners in all parts of Canada can be given to the public—such medium to be a monthly publication.

"This would have a tendency to bring our mining industries constantly before the public and to educate them to take an interest in sound and legitimate mining enterprises, besides giving to the world at large constant information about mineral development in Canada compiled from records and reports of a mining bureau under Government control which would be authentic and reliable."

SUGGESTIONS.

1. That a mining and mineralogical branch of the Geological Survey be established which will publish its reports separately and annually, such a branch to be presided over by an independent officer.

2. That separate reports be published at the beginning of each year of all work accomplished during the preceding year under this head throughout the Dominion.

3. That agents be appointed in the mining districts of all the provinces for the purpose of collecting and forwarding to Ottawa a monthly report containing information and statistics in connection with mines and minerals in their respective districts; also, that such information should be given in advance sheets to the public.

4. That a clause might be inserted in the Census Act, compelling miners to make periodical returns to the Government, annually or more frequently.

5. That a public assayer be appointed with residence at a central point for the convenience of prospectors in Dominion Territory in the North-west, and railway belt of the Rocky Mountains, whose duty it would be to forward to Ottawa monthly reports of the work done.

Mr. Dawson, of Algoma, stated to the Minister that Mr. W. Hamilton Merritt, Mining Engineer, had given this matter attention for some years back, and he, therefore, called upon him to explain the purpose and desire of the deputation.

Mr. Merritt stated that the important deputation was composed of gentlemen who were personally interested in mining development, or represented constituencies having large mineral interests, and that they wished to draw attention to the advisability of organizing a mining bureau or a separate branch of the Geological Survey, to give exclusive attention to mines and minerals, which had been much neglected in the past, and of which there were practically no records available at present. He also drew attention to the memorandum submitted to the Minister, and reminded him of the opinions expressed at the meeting of the British Association held in Montreal in 1884, when some of the leading members of the Association regretted that there existed no available records of Canadian mining and minerals, or statistics connected therewith, and spoke very strongly in favor of prompt steps being taken to supply this want.

Mr. Dawson, of Algoma, followed by stating that as he represented a constituency interested in mining he was in a position, as a result of many years experience, to know the great necessity of devising some policy that would advance the mining interests of Canada more or less in the direction as set forth in the memorandum which had been submitted.

Mr. Hall, of Sherbrooke, stated that this influential deputation had waited on the Minister more for the purpose of introducing this important subject to him than of dictating any definite policy. He said that the information he had received while acting on the Committee on Geological Survey convinced him that it was necessary to take some steps toward advancing the development of our mining interests.

Mr. Leckie, manager of the Spring Hill, N.S., coal mines, and Orford Copper mines in the Eastern Townships, pointed out the benefit of a

law compelling miners to make returns of mining statistics as practised in Nova Scotia.

Mr. Reid, of Cariboo, B.C., made some forcible remarks and expressed himself in sympathy with those gentlemen who had spoken before him.

Each gentleman present said something in favor of the movement, and after a few cordial remarks from the Minister, the deputation withdrew.

GATINEAU VALLEY RAILWAY.

The President of the Company Reports Progress.

CAUSE OF DELAY REMOVED.

WORK TO BE CONTINUED IN MAY.

A meeting was convened in the City Hall, Hull, on the 11th inst., to discuss the present position of the affairs of the Gatineau Valley Railway Company and the prospects for the early completion of the road.

The meeting was attended by quite three hundred persons, mostly residents of the district, among whom were many of the leading men of the County and City of Ottawa, including Messrs. Alonzo Wright, M.P.; C. H. Mackintosh, M.P.; Dr. Duhamel, M.P.P.; F. McDougall, Mayor of Ottawa; A. Rochon, Mayor of Hull; Rev. Father Guay, of Wright; Rev. Father Harnois, O.M.I.; Rev. Father Faure, of Masham; and Aldermen Heney, Cox, Durocher, and City Engineer Surtrees, of Ottawa.

The chair was occupied by Warden Cormier, who stated that the meeting had been called for the purpose of giving the representatives of the Gatineau Valley Railway Company an opportunity to explain what was being done towards resuming the work of construction, and added that he hoped, in the event of the company showing that they were prepared to proceed with active work in the spring, the county would give them substantial assistance and encouragement.

On motion of Mr. Joshua Ellard that Mr. C. H. Mackintosh, M.P., President of the company, be heard, that gentlemen addressed the meeting. After giving a resumé of the company's past history, Mr. Mackintosh referred to his constant and earnest appeals to the Provincial Government to locate the lands granted as subsidy, and pointed out how impossible it had been to establish a value for this important subsidy until the lands had been definitely located. He was gratified, however, to be able to inform the meeting that the Premier, Mr. Ross, had become convinced that the location of the lands must precede the survey, and had, jointly with Mr. Lynch, Commissioner of Crown Lands, written him a satisfactory letter on this question. Mr. Mackintosh concluded by saying that he had promised to carry the enterprise through, and that he firmly believed the completion of the road would be an accomplished fact within a year and a half.

Mr. Alonzo Wright, M.P., followed with some practical suggestions and reminded the meeting that works of this magnitude could not be constructed without obstacles presenting themselves. He was aware that the delay had been largely due to the Quebec Government's action in refusing to locate the lands, and said that from what he had learned from Mr. Mackintosh he felt confident that this important scheme would shortly be carried to a successful issue. He thought that if Mr. Mackintosh did not realize his expectations within a reasonable time he would be willing to hand over the charter.

Rev. Father Guay wished to know what might be considered a reasonable time, and was informed by Mr. Mackintosh that a reliable company had entered into a binding agreement to begin the work in May if the Quebec Government would but locate the lands.

Dr. Duhamel, M.P.P., expressed his pleasure at hearing that the Quebec Government had at last consented to locate the lands, and added that if the government subsidies were insufficient he hoped the people of Ottawa county and the cities of Hull and Ottawa would do all in their power to induce the Government to give more aid.

After some remarks from Mayor McDougall, McLogne and others, Mr. Joshua Ellard moved the following resolution which was carried unanimously:

Resolved, that after having heard the explanations of Mr. C. H. Mackintosh M. P., and his promise to continue the construction by the 15th of May, 1886, and to rapidly complete the road, this meeting and the inhabitants of the Gatineau will be satisfied and gratified if that promise is carried into execution, and that this meeting warmly and earnestly urges the Provincial Government to finally locate the land subsidies, and to prepare a map showing the same."

THUNDER BAY SILVER MINES.

A St. Paul Co'y at Silver Mountain.

AN ENCOURAGING OUTLOOK.

The representative of a St. Paul syndicate, Mr. P. M. French, arrived in Port Arthur on 23rd February to prepare for early mining operations in the Silver Mountain district on a location in which he and several St. Paul capitalists are interested. They have ample capital and every confidence in the future of this mining section. Supplies and heavy freight will be taken in before the winter roads break up and buildings are already in course of construction. As soon as navigation opens a large force will be engaged in developing a promising lode, and mining will be proceeded with uninterruptedly. Some prospecting work has already been done, the result of which has determined the gentlemen now interested to prepare for permanent and systematic operations.

Regarding the Rabbit Mountain group, a correspondent of the *Montreal Herald* has written an interesting account to that paper of his observations during a comparatively recent visit to that locality. He says: "Referring to the mining district of Thunder Bay, Lake Superior, I have recently visited the Rabbit Mountain series of mines and beg to submit these notes of personal examination and enquiries about the mining industries in that section, first premising that I went there purely from curiosity, and have no personal interest in the country.

RABBIT MOUNTAIN,

so-called, is on a cluster of hills and bluffs located about 25 miles from Port Arthur and 12 miles from Murillo station, on the Canadian Pacific Railway. I found in this vicinity, and within a radius of three miles, five working silver mines, viz, the Rabbit Mountain, Beaver, Silver Creek, Porcupine and the Rabbit Mountain Junior, the latter doing prospecting work on an adjoining claim or location, which carries the original Rabbit Mountain vein (which is exceed-

ingly rich), and is owned and quietly operated by a company composed largely of St. Paul gentlemen. The main shaft of this company is down 140 feet, which is as far as they can operate it with the machinery on the ground. They are about erecting a stamp mill, and have a large quantity of good stamp rock in the dump ready for its operation. They have selected the high grade smelting ore, which will pay the expense of hauling to the station, and rail to smelting works at New York, and have already shipped several car loads, which have returned a handsome profit, and have several more ready to ship, although the fact is apparent that they have only been playing with the property thus far.

A share of

THE BEAVER MINE.

has been recently purchased by a wealthy lumberman of Manistee, Michigan, who is developing it in earnest and is already getting the machinery on the ground for steam drills, and the Manager is in New York purchasing stamp machinery. The "Beaver" vein, which cuts a bluff 240 feet high, seems to be most admirably and conveniently situated for working. On the northern slope of the bluff the vein has been uncovered downward a distance of fifty feet, showing rich silver ore all the way from the first fifteen feet, where the vein is in the trap rock. At the bottom of this open cut, fifty feet from the top of the bluff, is the first "adit level," which has been cut into the hill some sixty feet and has produced good stamp rock all the way. At the base of the bluff a tunnel has been driven 265 feet, the last twenty feet being on the vein which is very clearly defined between the slate and is here apparently rich in silver. On the southern slope of the bluff another level has been started to meet the upper level on the northern side before referred to. This level is in forty-five feet and produced good stamp-rock all the way, so there is plenty of material for the mill as soon as it can be erected. It does not require an expert to see that the "Beaver" vein is a good one, as its extent is so plainly visible and it has paid its way upon every working, and the location seems to possess every natural advantage that could be desired for cheap mining.

THE SILVER CREEK VEIN

also cuts a bluff which is now being penetrated by an adit level driven on the vein in the silver slates immediately under the trap rock of the surface. It is now producing good stamp rock in considerable quantity, which will be treated by the Beaver mill, and has also produced quite an amount of high grade ore in native and black silver. This property seems well situated for cheap and extensive mining, with Silver Creek flowing through it and furnishing abundance of good water.

The picturesque and convenient location of

THE PORCUPINE MINE

is within a mile of the Whitefish River and very much resembles the Silver Creek Mine, and, like it, is producing rich smelting ore in both native and black silver, and all of its vein rock will pay for working. It has a large dump of stamp rock ready for the mill, and a large value of high grade smelting ore has been shipped away. I was informed that an interest could be purchased in this mine, but did not learn the figure.

Around this cluster of working mines there are said to be several other outcrops of veins which are not yet developed. The good results which have been obtained from the work now going on at these mines have increased the interest in them by their respective owners to

that extent as to probably lead to a decided improvement in their manner of working and correspondingly rich results the coming season.

Further to the west again, about fourteen miles from the Porcupine mine, and in the same geological formation, is

THE SILVER MOUNTAIN,

which the writer did not visit, and will, therefore, say nothing about, or about the gold country still further west, and about 70 miles from Port Arthur. There seems to be every requisite for successful mining in this section of Canada, and it seems very strange that Canadians do not investigate its value. Investments so far have been mostly by capital from the States, and the investors appear particularly satisfied, as none of them wish to sell.

It was a surprise to find so much land in the vicinity of these mines which was apparently well adapted

FOR AGRICULTURAL PURPOSES.

With a miner's market for his products, the farmer who locates here will find a better investment than any prairie land, provided he has energy enough to clear the timber, which alone would pay for his farm. It is said that this country has been but little explored. It certainly warrants a careful examination, and what is already developed indicates great mineral resources which are only awaiting capital and better highway and railway facilities to compete with Colorado production."

Mr. A. F. Fletcher, M.P., who has had a wide experience in mine development in the principal mining centres of the world, has recently visited the Silver Mountain district in the interest of New York capitalists. On his return to Port Arthur, he expressed himself to a *Sentinel* reporter in the following terms:

"I am much pleased with the very rich showing of silver ores I have seen at the mines during my visit to Silver Mountain, and consider that capital, under the management of wise and experienced mining men, is all that is required to make the locality a flourishing and prosperous mining region in a short time.

The rock formation consists of slightly inclined strata of trap and sedimentary black, argillaceous and silicious slates, intercepted by true fissures, in which the silver occurs. The character of the formations is such that more than ordinary knowledge of formations is required by the management of mining development, otherwise much waste of capital is likely to result.

I may also mention that considering the much need of capital to open up these mines, and the undeveloped state and character of the same, I consider that the owners of mining claims in general are placing too high an estimate on their properties to induce the desired capital into the district."

Owners of mining claims will find it to their advantage to seriously consider the wisdom of Mr. Fletcher's opinion and the justice of his rebuke. It should be always borne in mind that a *prospect* is not a *mine*, that a mining claim does not possess intrinsic value until developed, and that to carry on development work requires capital. Owners will, therefore, find it greatly to their advantage, and it certainly would be an advantage to our mining industry in general, if they will be but reasonable in their demands, and hold out inducement to capitalists to come forward and develop their claims in order that they may become productive and profitable. — [Ed.]

NOVA SCOTIA GOLD FIELDS.

"PAY STREAKS."

The Editor Canadian Mining Review:

DEAR SIR—I have been much interested in Mr. Kinahan's letter on this subject in your last issue. I think that he does not quite understand the peculiarities of our gold districts. We have an immense number of comparatively small veins, running almost without exception parallel to the beds of slate and quartzite composing our gold measures. Thus a trench 150 feet long has exposed twenty veins, and similar results have been observed at depths up to 400 feet. These veins occur along the denuded crests of anticlinal folds, and it is considered that they occupy the fissures and lines of minimum pressure presented during the progress of the folding. It will be noted that our worked veins seldom exceed fifteen inches in width, and a pay-streak occupies the whole width of the vein. Thus each of these veins is practically a separate lead, and I cannot recall an instance of two neighboring veins having pay-streaks at all parallel. I gather from Mr. Kinahan's remarks that he refers to wide ore grounds. We have instances of this in the large vein of ankerite carrying limonite at Londonderry, and in the Precambrian of Cape Breton where lenticular bodies of copper pyrites occur in a thick bed of felsite. In both these mines the arrangement of the ore bodies is as described in the mine of Ovoca,—and the system of prospecting by cross-cuts is regularly practised. The pay-streak in our gold veins may be described as a line or point of maximum richness surrounded by somewhat less auriferous quartz, which gradually becomes poorer until the pay-streak ends at the line of profit. Such pay-streaks, with occasional exceptions, have a dip approaching the vertical, and in one instance at least have been followed for about 600 feet. As the veins are those of segregation, and possibly contemporaneous with the folding already referred to, the source of the gold must be looked for in the surrounding rocks. It is well known that the slates are frequently, the quartzites occasionally, auriferous; and that in each district there is a rule that all the pay-streaks dip either to the east or to the west, (the veins having an approximate east and west course.) The cause, therefore, producing these pay-streaks must be uniform throughout each district. With an apparent uniformity of distribution of gold through the encasing beds the enrichment of the veins might be sought for in local lines of comparatively greater transverse disturbance having a uniform dip due to the conditions of folding and upheaval in each district. By this means gold might be concentrated more readily along certain favouring lines and the enriching effect of feeders and flat leads lends ground to this view. If, however, the gold has been originally precipitated, possibly through the effects of organic matter, along certain lines, e.g. of a shore or beach, in comparatively narrow and frequently limited zones, then in each district, after the beds had been hardened, elevated, folded, etc., it might be assumed that portions of the veins nearest to this rich ground would receive the gold in a concentrated form. However such original causes may have laid the foundation of pay-streaks, subsequent faults, movements, etc., have in all probability greatly modified them. Practically, cross-cuts have been repeatedly driven across the measures when these rich zones have been worked out, but hitherto unsuccessfully. And now the miners agree that the chances of

success lie in trying for the possible downward extension, after a barren interval of the pay ore.

Possibly, Mr. Editor, some of your readers better qualified than I am, may throw some light on this subject of pay-streaks which is exciting a good deal of interest in our mining circles at present, and I remain,

Yours very truly,

E. GILPIN, JR.

SELL COAL BY ASSAY, LIKE ORES.

Mr. C. A. Ashburner has given, in a paper read before the American Institute of Mining Engineers, an interesting discussion of this subject.

The figures obtained by Mr. Ashburner from average samples of anthracite coal just as it is shipped to market are very interesting, as showing that the percentage of ash is always much higher than is generally supposed, and as showing that the commonly received analyses must be taken as representing only picked samples. It would be a very easy matter to sample the coals as they are shipped by an automatic sampler that would give a correct average. And we hope something of the kind will be done. In the meantime, Mr. Ashburner's sampling and analyses are extremely instructive if not startling, and show the advisability of buying coal by analyses, as ores are purchased. This is the only way in which the purchaser will be sure of getting what he wants. There would be no difficulty in establishing a scale of fuel ratios that would represent the actual economic value of coals containing given percentages of ash and fixed carbons, and the sampling and analyses could be very cheaply and easily made.

It is certainly very remarkable that so important and expensive an article as coal should be purchased without any test whatever of its value, and merely on the "say so" of the vendor.

The company that will introduce this system of selling coal by analyses, or by its economic value as determined by actual test, will be a public benefactor, and will certainly gain a large business.—*Engineering and Mining Journal*.

On next page will be found an article, by Mr. A. Tournet, on this very subject, descriptive of the practice of purchasing coal by analysis which has been rigorously adhered to by the large railway corporations of France for many years back.

The discovery of gold in Honduras is likely to prove as important as any of the great placer districts of California. The new gold field is in the eastern portion of the republic of Honduras, about 150 miles from the Atlantic coast and adjacent waters of the Gnyope River. In some places the ground yields \$7 to \$10 per cubic yard.

La Trinidad (of Sonora): We regret to see that the English promoters of this property persist in paying dividends that are not derived from the product of the mines, one having been declared on the 28th of January, 1886, of \$1.25 per share on the capital stock, or \$125,000. We once more warn our English friends against being gulled in this transparent way. Including this dividend, this company now stand before the English public as having paid the shareholders three dividends, each of \$125,000, or in the aggregate \$375,000, an amount that we confidently assert was not derived in bullion from La Trinidad mines in 1885 over and above cost of extraction.—*Financial & Mining Record*.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

Descriptive and Determinative Mineralogy.

The science of mineralogy has few students and fewer proficient; it is certainly one of the most neglected amongst the natural sciences. Yet its influence and importance would be obvious if public attention were once drawn to the many services our science renders to modern society. In fact, without mineralogy it is difficult to conceive what would become of our boasted civilization. Lack of beauty and interest cannot be consistently urged as a plea for the surprising neglect to which this science is consigned by otherwise well educated persons.

In our opinion the only reason why mineralogy is so little appreciated is the in attractive form in which it is presented to the beginner. Many a study once deemed unbearable to the youthful mind is now to be found in every programme of studies, even those of public schools. Why? Simply because skilled educators discovered the proper method of instruction in that particular line of study. Sooner or later the same success must attend the teaching of mineralogy.

Two methods dispute the field of mineralogical teaching, the descriptive and the determinative. The former presents at a single glance the complete system of the science, ranges each species in its natural order, and then enters into the details and characteristics of each; the latter at the outset only draws certain lines of classification, and opens up many divergent paths, which if faithfully followed, will finally lead the mystified student by numerous ramifications and cross-roads, to this or that species without a single kindly allusion to its place in the mineral kingdom. The one throws at once upon the subject the full light of classified knowledge, and lays at the feet of the student the treasures painfully acquired by toiling generations of scientists; the other ushers the tyro into the dark labyrinth of determinative tables, presents him with a smoky taper and a frail thread and with a sparing hand doles out to him only such information as he has manfully battled for. The descriptive method is a beautiful list of answers richly illustrated; the determinative a series of knotty problems with jet black interrogation points for answers. The first is universally adopted in classical courses, and whenever only a limited time can be devoted to the study; the second is a favorite with all practical men and scientific students in general.

Now, which of these methods should be preferred for the young man who enters upon the elements of the science, for the man of the world who once in a while diverts his attention from daily duties to direct it to the study of nature? Which is preferable for the student for whom mineralogy is only one stone in the stately building of our high school and college educational systems? As we have already said, the descriptive method has been heretofore preferred in these circumstances; and many reasons tend to justify that choice. Clearness and precision are the two important qualities looked for in teachers and text-books, and in this respect descriptive mineralogy has an uncontested advantage. After laying down the general prin-

ciples of the science, explaining what is meant by the crystallographic, chemical and physical characteristics of minerals, it describes the species, each in the particular group in which its analogies have placed it, and after a uniform plan which permits the student to find immediately any property of such minerals as he may want to study.

Yet this method is objectionable in more than one respect. First, chemistry, the source of all the laws which regulate the intimate relations of matter, the ground-work of all natural history, but in a greater degree of mineralogical science, has been almost totally excluded from our text-books of descriptive mineralogy. The result of such omission can easily be anticipated. The description of minerals becomes little else than a long and tedious catalogue of species, with no other binding link than the heading of the group, the reason of which is no better understood than many of the characters which are so minutely detailed.

Again, if mind culture must be considered in the choice of a method, the descriptive, precisely because it removes all difficulties from the student's path, proves very defective; for it is the maxim of all educators that everything must be presented to the young in the interrogative form, and the solution be given as a reward for patient inquisitiveness. Without that, the learning of mineralogy is simply a work of the memory which tries to store away in the shelves of the mind those long lists of cacophonous names and obnoxious figures which, though they may represent hardness, specific gravity, fusibility, etc., are without an acquisition of doubtful utility for the young mind. Be that as it may, mineralogy thus presented is totally devoid of interest, and experience teaches that if a student preparing for examination or otherwise is compelled to learn this kind of science, he soon rids himself of such a burden the moment the pressure is removed from his mind.

What adds to the aridity of this method is the absence of personal experimentation on the part of the student. For even though you should place in his hands the necessary instruments and reagents, he is not inclined to verify properties so clearly affirmed by the learned author. But give him a specimen to determine, then as the solution depends upon the accuracy of his observations, curiosity, the inheritance of all men, gives a lively interest to every test and experiment. In this Determinative Mineralogy has a decided advantage. Must we, however, on that account, give it the preference? We hope, in our next issue, to give a satisfactory answer to this question.

Organization of Testing Departments in Railroad Companies.

The need and necessity of determining the value of everything, of ascertaining the purity of products or of metals, or of discovering falsifications or frauds, have been so generally recognized in France and in several other European countries, that all great companies, manufacturers and merchants, buy or sell nothing except on a bulletin of analysis, signed by a well known chemist.

The great railway companies that have their central administrations in Paris, have a very complete organization.

The testing department renders a continual service to these establishments, by causing such substances to be accepted as answer by their purity, or degree of purity, to the requirements and to the conditions imposed on the contractor; or again, by causing all defective substances to be rejected.

Each railroad company has a perfectly organized laboratory, and an experienced attendance charged with the chemical tests, and mechanical trials.

Railroad companies, as is known, consume a great quantity of fuel,—coal, coke, etc.; and consequently make important contracts with their suppliers.

Each contract is made by indicating the quantity of fuel to be delivered daily or by the month, at determined points: and the quantity of ashes, for a thousand parts, that these combustibles should leave after incineration, the quantity of gas produced, and that of coke obtained from the combustibles, as well as their calorific power are equally determined and stipulated in the contract.

What is more, the ashes are tested to determine the quantity of potash they contain; the ashes rich in potash are called fusible, they attack by corroding the bars of the grate of a locomotive and thus greatly diminish their durability.

When the fuel delivered is of better quality than stipulated for in the contract, the supplier receives a premium calculated according to the richness and price of the combustible; if on the contrary the combustible is inferior to what it should be, the contractor incurs a fine which is deducted from the payment, and which, like the premium, is calculated so much per cent. below the value that the fuel should have.

It is seen that this system is very equitable, as much so for the vender as for the buyer; everything encourages the contractor to deliver good combustibles.

As soon as the fuel arrives at the ports or stations, a sample is taken from each shipment and put in a special case which is then sealed and forwarded to the laboratory to have it appraised.

For those combustibles transported by cars, a sample is taken from each car; for *briquettes* a brick is taken from each car; for coal or coke a basket; each brick bears an inscription indicating the name of the contractor, the date of delivery, the number of the car, and the name of the station at which it was received; the *briquettes* as well as the coal and coke, are put in boxes and forwarded to the laboratory of the company where the chemists proceed to examine them.

The laboratory addresses every day to the principal inspector of the company, a detailed report on the combustibles tested, and every quarter a general table is drawn up, so as to settle with each contractor.

When a new contractor is accepted by a company, the laboratory is charged to seriously examine the value of the combustible that he offers, to see whether it does not contain property injurious to the working of the machine; in a word, the laboratory makes a complete analysis, and a thorough examination; it is this report that serves as the base for the conditions of the contract.

A. TOURCHOT.

Mineralogical Society.

There is not a city in the Dominion which, in proportion to its population, affords more facilities to the lover of science than Ottawa.

Apart from its many other advantages, its literary and scientific societies are so numerous and prosperous as to deserve special recognition. One of these in particular, the Mineralogical Society of the College of Ottawa, cannot fail to interest the readers of the MINING REVIEW.

To the kindness of its Director we owe the following interesting details concerning its object and constitution.

The general object of that association is to promote the study of mineralogy and the allied sciences, chemistry and geology. It attains that object in a twofold manner—first, by encouraging personal investigation and discovery, and affording persons already conversant with scientific subjects an opportunity of exchanging and discussing ideas on the same; secondly, by fostering a taste for these studies among the students of the college and other young men, and, at the same time, acquainting them with the fundamental principles of mineral chemistry and geology.

The membership of the Mineralogy Society is open not only to students of the University, but to all outsiders interested in science. It includes Professors of the Faculty and other scientific gentlemen, as well as students and other young men standing on more or less advanced steps of the scientific ladder. Persons wishing to become members should apply to the secretary.

Meetings are held every Wednesday at 5 p. m., at which original papers are read and discussed, and popular science lectures are given, accompanied by experiments. Admission to the meetings is free, and a general admission ticket may be obtained by applying to the President of the Society. The chemical and mineralogical laboratory and museum of the College, which will soon be completed, are put at the disposal of members; and all necessary apparatus and reagents are furnished on special conditions.

In order to increase its sphere of usefulness, the Mineralogical Society respectfully requests the co-operation of the science-loving public, and particularly of those interested in mines, quarries, etc. Information of any kind and specimens of minerals, rocks and fossils are thankfully received; in return, the Society makes a determination of such specimens when requested and inserts the names of the donors in its publication. The society, having secured the services of the College Professor of Chemistry and of an eminent French chemist and analyst, is now in a position to supply the daily increasing demand for mineral analyses.

The Society was formed in March, 1880, by the Rev. C. F. Marsan, O.M.I., M.A., Professor of Chemistry, Mineralogy and Geology in the College of Ottawa, with the assistance of Mr. (now Honorable) P. S. Poirier, and other scientific gentlemen. Hon. Senator Poirier, whilst Postmaster of the House of Commons, occupied the presidential chair of the Society till the beginning of the present year, when his removal to the Maritime Provinces made it impossible for him any longer to conduct the business of the Society.

The following are the officers for the present year:—

Director: Rev. Prof. C. F. Marsan, O.M.I., M.A.

President: Mr. Walter A. Herckenrath, of Mamaroneck, N. Y.

Vice-President: Mr. Wade Smith.

Recording Secretary: Mr. Jas. Foley.

Scientific Secretary: Mr. Alfred Lussier.

Treasurer: Mr. Patrick Griffin.

Chemist: Mr. Anatole Tourchot.

Librarian: Mr. David Phalen.

Curator of Museum: Mr. Duncan Campbell.

Scientific Committee: Rev. James Moloney, O.M.I.; Rev. Germain Gauvreau, O.M.I.

Pennsylvania made 68 per cent. of all the Bessemer steel rails, and 65 per cent. of all the ingots produced in the United States in 1885.

SCIENTIFIC NOTES.

SULPHUR.—It is reported that large deposits of sulphur have been recently discovered on the southern slopes of the Caucasus Mountains.

QUARTZ.—There seems to be a dispute, at present, as to whether the permanent polarity of quartz, lately discovered by Dr. Tumlirz, is diamagnetic or paramagnetic.

VESUVIUS.—After the late eruption of Vesuvius, on Feb. 6, the chloride crusts of lava in the vicinity were found to be very rich in copper, so that the bootnails of visitors to the spot became thickly plated with it.

WATER GAS.—A series of experiments in the reduction of iron ores, carbon monoxide, superheated steam, and water gas being employed as reagents, gave the following total results of oxidation for one series of specimens: Carbon monoxide 81.12 degrees, steam 84.75 degrees, water gas 86.48 degrees, thus giving water gas an advantage of 5.38 degrees over carbon monoxide, and 1.73 degrees over superheated steam.

HEAT.—A recent writer in the *Geological Magazine* ventilates an idea that is certainly novel and original, viz.: that the interior heat of the earth will yet be utilized by man. He is of opinion that the crust, which separates us from the molten mass below, is not so thick as is generally supposed, and considers it one of the possibilities of the future that we shall 'bore down to the liquid layer, and conduct our smelting operations at the pit's mouth.'

MINERALOGY.—The author of the *Rudiments of Mineralogy*, recently published by Crosby & Lockwood, London, has devised a new torment for beginners. In addition to the specific gravity of elements as compared with water, which learners usually find sufficiently difficult to remember, Mr. Ramsay gives the specific gravity taking hydrogen as the standard unit. As an example of what students are required to tax their memories with, the specific gravity of native silver is given as ranging from 115, 123 to 117, 369.

GEOLOGY.—The latest as well as one of the most important contributions to geological science is, *Geology, Chemical, Physical and Stratigraphical*, by Prof. Prestwich, of Oxford University, the first volume of which has just been issued from the Clarendon Press. Those portions of work are particularly valuable, which embody the results of the learned Professor's original researches. Prof. Prestwich belongs to the non-uniformitarian school of geologists, holding that the action of physical forces in the geological periods constantly varied in degree and intensity.

BOOK NOTICES.

AN INTRODUCTION TO THE STUDY OF THE COMPOUNDS OF CARBON, OR ORGANIC CHEMISTRY, By Ira Remsen. Ginn, Heath & Co., Boston, 1885.

This excellent text book, though published a few months ago, is very little known in Canada, we have therefore much pleasure in bringing it to the notice of our readers. It is impossible, in a brief sketch, to enumerate all the merits of this book. The author has evidently written it for students beginning the study of the com-

pounds of carbon with or even without a teacher. He carefully avoids, in the beginning, long theoretical considerations from which the beginners can derive no benefit. Throughout the book the relations of various series, the general properties of groups, and important laws of formation, are indicated only after the facts illustrating them have been described and experimented upon. Nothing so confuses the student as the grouping together of a mass of laws and speculations before acquainting him with facts, thus giving him the very false notion that natural science is a kind of castle in the air, too distant for clear observation. Another very common defect, from which Mr. Remsen's work is free, is excessive comprehensiveness. All cannot be told in a text book, so that if an author attempt to give the abridged history of every compound, his work becomes nothing but a dry nomenclature of facts and formulas. It is far better to choose some typical compound in each series, and give a full description of it; the knowledge then conveyed will be complete in its kind, and the student may afterwards, by himself, repeat the same work upon each of the other members of that series. To those acquainted with Wentworth's *Geometry*, or any other of the classical publications of Ginn & Heath, it is needless to say that this edition is a masterpiece of typographical neatness and beauty.

OTTAWA FIELD NATURALIST'S CLUB: Transactions No. 6; Vol. II, No. 2.

We have just received this, the best publication yet issued by our local scientific club. It has only one defect, it comes too late, and the reader cannot but feel disappointed when he finds out that all the papers included in that volume were delivered before March, 1885. Many of those papers are very interesting. We published in our issue of February, 1885, the paper of Mr. Chas. Willmott, "Minerals of the Ottawa District." Among other valuable papers Mr. William Lett's very interesting essay on the "Canadian Otter" deserves special notice. Mr. Latchford's "Observations on the Terrestrial Mollusca of Ottawa and Vicinity," must necessarily be in the hands of all students of our shells. Finally, geologists will find a valuable addition to our knowledge of the Trenton fossils in the notes on "Two New Species of Crinoids," by Mr. Walter R. Billings.

MINING NOTES.

NOVA SCOTIA.

It is reported that a rich gold lead has been discovered in Yarmouth county, not far from Pubnico.

Active prospecting was carried on in Lunenburg and Queen's counties last autumn, and the discovery of some important gold-bearing quartz veins was the result.

During the past month gold was discovered at Carlton, Yarmouth County, and applications for licenses to work have been made to the mines department at Halifax.

Early in February, two gold bricks were brought to Halifax from the Salmon River and Rawdon mines. That from the former weighed 1,297 ounces, and from the latter, 155 ounces.

The discovery near Nictaux, Annapolis County, made some months ago has led to the discovery of several other quartz veins showing free gold.

A stamp-mill is to be established at the McGuire gold mine at Whitburn, Pictou County, and owners of adjoining areas have consented to co-operate in defraying the cost of its erection and equipment.

Mr. James Fraser is making a determined effort to have the mining laws of the province amended. As they stand at present, they are in some respects inconsistent, although generally liberal and equitable.

The Pleasant River gold mine has been sold to a Duluth firm for \$19,000. The property has been fairly developed and promises well. The main shaft is down 35 feet, and some of the quartz now being taken out, carries 2 oz. in gold to the ton.

Recent operations by the Kempt Gold Mining Company at their mine at Little Lake, near Kemptville, have disclosed a remarkably rich lead. This has had the effect of establishing the value of Yarmouth County gold mines and the shareholders of the Kempt Company are much encouraged.

In the Oldham district there are 40 gold-bearing leads, and the output, up to the present time, has been about 2,500 oz. For many years, gold-mining in Oldham was carried on in a primitive style, trenches being made to the depth of 20 feet, which, after the quartz was taken out, were allowed to fill with water.

NEW BRUNSWICK.

There is every prospect that activity will be seen during the coming summer at the Manganese mines in this province, notably in Albert County.

Development work will in all probability be started shortly on some important leads of stibnite discovered last autumn. Samples of the ore were assayed in New York, and found to carry 65 per cent. of antimony.

A sample of quartz from a three inch lead recently discovered near Sackville, Westmoreland County, has been analyzed in New York, and found to contain 5 oz. of gold to the ton. Experts believe that the lead increases in width below the surface.

QUEBEC.

An average of 65 men have been employed at the "Emerald" mine, Ottawa County, during the winter, and by the time navigation opens there will be upwards of 3,000 tons of phosphate ready for shipping.

The Phosphate of Lime Company have given employment to 120 men during the winter at their "High Rock" mine in Portland West, Ottawa County, and will have 3,200 tons of ore on hand for shipment when navigation opens.

Since the shipping season closed last autumn the Dominion Company have raised 3,000 tons of phosphate from their "North Star" mine in Portland West, Ottawa County, and have given employment to an average of 75 men.

We are informed that the Union Company have done good work during the winter at their mines in Portland West and have a large quantity of phosphate ready to go forward, but we have not received further particulars.

Great activity prevails at the Colrairie Asbestos Mines. The Anglo Canadian Asbestos Company have a large force at work and are putting in air-compressors, steam-pumps and drills, and other expensive machinery, with a view to equipping their mine for permanent and extensive working.

At the St. Onge Gold Mining Company's Mine, at St. George East, Beauce, work has progressed rapidly during the past month. A drift is being run from main shaft towards the centre of the old river bed. Much rich ground has been crossed by the drift and a quantity of coarse gold taken out. The objective point is now but a short distance from the end of the drift, and when reached it is confidently expected that marvellously rich ground will be found on bed rock.

ONTARIO.

(Thunder Bay District.)

Many specimens of rich ore from the east end of Silver Mountain have been forwarded by the mineral committee to the Colonial and Indian Exhibition.

Surveyor McDougall and party have returned from a new discovery which they have surveyed and Surveyor Russell is now engaged in laying out still another.

Work has been resumed on the east end of Silver Mountain and it is stated that silver is visible in the ore taken out and lying in the drift made by the Cleveland company.

It is currently reported that the Crown Point mine, a quarter of a mile north of the east end of Silver Mountain, has been sold to American capitalists who intend erecting a stamp-mill without delay.

The Peerless Mining Company, of Lake Linden, Michigan, affirm that they will soon begin to operate a claim located by their agents last year about 3 miles S. W. of the Porcupine mine.

The Algoma Mines Company have received estimates for crushing and concentrating machinery to be erected at their mines near Black Bay, about 35 miles east of Port Arthur, and will, it is thought, proceed with active mining and milling early in the spring.

Medicine Bluff, at the southwest end of Whitefish Lake, is described as a valuable location, 400 feet in height, slate capped with trap, and having veins carrying silver, gold, copper, iron, alum, etc. A tunnel some thirty feet in length has been driven into the hill to cut the vein about 250 feet below the summit.

BRITISH COLUMBIA.

There are over 1,500 miners in the Granite creek, Colville and Similkamien districts, and it is expected that the number will reach 20,000 before the middle of summer.—*Yakimer Signal*.

Twenty odd white men and a number of Chinamen have started in to prepare for active mining on Scotch Creek. Reports from this camp are very favourable, and the Shuswap drift is progressing well.

The advisability of establishing a trail between Yale and Granite Creek mines is being seriously considered. It is claimed that a practical trail can be found from Yale to the mines that will not be more than half the length of the present route.

Miners have started in to work on Granite Creek and are getting good returns. Other creeks, viz., Slate, Cedar, Champion and Collins, are nearly all taken up and active preparations are going ahead for mining as soon as the ground is clear of snow.

The Tulameen river seems likely to be the principal mining ground during the coming season. The Chinese last year took out a large amount of gold; but the whites got in too late to allow of working their claims—they were, however, all well prospected.

NEWFOUNDLAND.

Capitalists have taken up the Placentia mines and will work them to some extent in the near future.

A new and valuable discovery has been reported at Bett's Cove, where the copper mines have been comparatively idle of late.

The Briggs gold field has been favourably reported on by mining experts, and as auriferous quartz occurs in quantity in that region, it is expected that gold mining will be engaged in ere long.

At Little Bay copper mine, operations have been resumed under a new management. Two hundred men are now at work, and when spring opens, it is not improbable that 600 to 700 men will be employed.

Last summer Newfoundland was visited by a number of mining engineers for the purpose of inspecting certain mineral deposits. They were favourably impressed with the prospects for the future of mining industries on the island.

UNITED STATES.

All of the iron mines in the vicinity of Hillarton, Lehigh Co., Pa., are in active operation.

The present outlook for ignot copper is favourable, there being very little spot coppers now on hand.

Dividends to the amount of \$1,152,450 were paid by United States mining companies in the month of January.

Of the 4,529,869 net tons of pig iron produced in the United States in 1885, Pennsylvania made 2,445,496 tons, or over 56 per cent. of the total.

The report of the Father de Smet mine, presented at the annual meeting, shows that 106,855 tons of ore, of an average value of \$3.57, were milled during 1885. The receipts were \$381,697.41; disbursements \$226,100.66, leaving annual profit of \$155,596.75.

NOTICE TO CONTRACTORS.

CHANGE OF TIME.

THE time for seeing the plans and specifications for the

INFANTRY SCHOOL

—AT—

LONDON, ONT.,

Is hereby changed to TUESDAY, the 23rd instant, and the time for receiving tenders to WEDNESDAY, the 7th APRIL.

By order,
A. GOBEIL,
Secretary.

Department of Public Works,
Ottawa, 12th March, 1886.

SEALED TENDERS, marked "For mounted Police Clothing Supplies," and addressed to the Hon. the President of the Privy Council, Ottawa, will be received up to noon Thursday, 18th March, 1886.

Printed forms of Tender, containing full information as to the articles and quantities required, may be had on application to the undersigned.

No tenders will be received unless made on such printed forms. Patterns of all articles may be seen at the office of the undersigned.

Each Tender must be accompanied by an accepted Canadian bank cheque for an amount equal to ten per cent. of the total value of the articles tendered for, which will be forfeited if the party making the tender declines to enter into a contract when called upon to do so, or if he fails to complete the service contracted for. If the tender be not accepted the cheque will be returned.

No payment will be made to newspapers inserting this advertisement without authority having been first obtained.

FRED. WHITE,
Comptroller,
N. W. M. Police.
Ottawa, Feb., 24th, 1886.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with,—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein,—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section,—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

NOTICE

TENDERS will be received by the Department of Inland Revenue until Monday, 12th April, prox., from parties desirous of leasing the privilege of ferrying across the Ottawa River, between the village of New Edinburgh, in the Province of Ontario, and the village of Waterloo or Gatineau Point, in the Province of Quebec, in accordance with the terms and under the conditions set forth in the Regulations, copies of which can be procured at the Department of Inland Revenue, Ottawa.

Each tender must state the amount which the party tendering is willing to pay per annum for the privilege referred to, which amount will be payable in advance, the terms of the lease being for four years and eleven months, from 1st May, 1886.

Each tender must be accompanied by a cheque marked "Good" on one of the chartered banks doing business at Ottawa, for one-half the amount of the per annum tender. This amount will be credited on account of the first year's rent in the case of the accepted tender, and all other cheques will be returned except in the event of withdrawals, in which cases no refunds will be made.

All communications must be addressed to the undersigned and endorsed on the envelope "Tender for the New Edinburgh Ferry."

By order,
WM. HIMSWORTH,
Secretary.

Department of Inland Revenue,
Ottawa, March 18th, 1886.

NOTICE.

TENDERS will be received by the Department of Inland Revenue until Monday, 12th April prox., from parties desirous of leasing the privilege of ferrying across the Ottawa River, between the City of Ottawa, in the Province of Ontario, and the City of Hull, in the Province of Quebec, in accordance with the terms and under the conditions set forth in the Regulations,—copies of which can be procured at the Department of Inland Revenue, Ottawa.

Each tender must state the amount which the party tendering is willing to pay per annum for the privilege referred to, which amount will be payable in advance, the terms of lease being for four years and eleven months from 1st June, 1886.

Each tender must be accompanied by a cheque marked "good" on one of the chartered banks doing business at Ottawa, for one-half the amount of the per annum tender. This amount will be credited on account of the first year's rent in the case of the accepted tender, except in the event of withdrawals, in which case no refund will be made.

All communications must be addressed to the undersigned and endorsed on the envelope "Tender for the Ottawa and Hull Ferry."

By Order,
WM. HIMSWORTH,
Secretary.

Department of Inland Revenue,
Ottawa, March 18th, 1886.

North-West Mounted Police TENDERS FOR HORSES.

SEALED TENDERS, marked "Tenders for Horses," and addressed to the Hon. the President of the Privy Council, Ottawa, will be received up to noon, Monday, March 29th, 1886, for supplying 100 SADDLE and 100 TEAM HORSES for the Mounted Police, to be delivered at Regina, North-West Territories, not later than April 24th.

Tenders to state the price per horse in each class, team or saddle, and may be or any number not less than one car load.

An officer of Police and a Veterinary Surgeon will examine the horses prior to shipment from Ontario and Quebec, but they will be at Contractor's risk and expense, and will not be paid for until delivered at Regina. Horses injured or falling sick in transit will not be taken over at Regina until fully recovered.

Parties tendering must state the date on which their horses will be ready, and the Railroad Station in Ontario or Quebec they select for inspection.

DESCRIPTION.

Team Horses, age 5 to 7 years, about 1,250 lbs., short-legged, active horses, sound and free from blemish, well broken, and good walkers.

Saddle Horses, age 5 to 7 years, height 15 to 15-3, well-bred sound horses, free from blemish, with good substance, appearance, and action, and well broken.

Each tender must be accompanied by an accepted Canadian bank cheque for an amount equal to ten per cent. of the total value of the horses tendered for, which will be forfeited if the party making the tender declines to enter into a contract when called upon to do so, or if he fails to produce suitable horses for inspection on the date specified in his contract, or to deliver them at Regina not later than the 24th April. If the tender be not accepted the cheque will be returned.

No payment will be made to newspapers inserting this advertisement without authority having been first obtained.

FRED WHITE,
Comptroller,
N. W. M. Police.

Ottawa, March 13th, 1886.

NOTICE.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Indian Supplies" will be received at this office up to noon of TUESDAY, 20th APRIL, 1886, for the delivery of Indian Supplies during the fiscal year ending 30th June, 1887, consisting of Flour, Bacon, Beef, Groceries, Ammunition, Twine, Oxen, Cows, Bulls, Agricultural Implements, Tools, etc., duty paid at various points in Manitoba and the North-west Territories.

Forms of Tender, giving full particulars relative to the Supplies required, dates of delivery, &c., may be had by applying to the undersigned, or to the Indian Commissioner at Regina, or to the Indian Office, Winnipeg.

Parties may tender for each description of goods (or for any portion of each description of goods) separately or for all the goods called for in the Schedules.

Each tender must be accompanied by an accepted cheque in favour of the Superintendent General of Indian Affairs on a Canadian Bank for at least five per cent. of the amount of the tenders for Manitoba and the North-west Territories, which will be forfeited if the party tendering declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted the cheque will be returned.

Tenders must make up in the Money columns in the Schedule the total money value of the goods they offer to supply, or their tender will not be entertained.

Each tender must, in addition to the signature of the tenderer, be signed by two sureties acceptable to the Department, for the proper performance of the contract.

In all cases where transportation may be only partial by rail, contractors must make proper arrangements for supplies to be forwarded at once from railway stations to their destination in the Government Warehouse at the point of delivery.

The lowest or any tender not necessarily accepted.

L. VANKOUGHNET,
Deputy of the Superintendent-General
of Indian Affairs.

Dept. of Indian Affairs,
Ottawa, 3rd March, 1886.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

We understand a start has been made towards preparing a statistical report of Canadian mines, and while we welcome this information we would express the hope that this very important work will be proceeded with without interruption.

It now looks as though the collection and publication of mining statistics will receive some attention from the Geological Survey, but we fear the staff which has been told off for this special work, with the meagre assistance at its command for collecting and compiling statistics, is quite inadequate to do justice to this important work. The ability of Messrs. Coste and Ingall, the two Mining Geologists of the Survey, to whom this special work has been assigned, is not brought into question, but it is unreasonable to expect that these two gentlemen, in addition to performing their professional duties in the field, as heretofore, can organize and conduct the mining and mineralogical branch of the Survey, and collect and compile statistics in connection therewith in a manner that will do themselves justice or satisfy the mining public. If the information that this work is to supply is to be of any value it must be full and complete. That it may be so, it will be necessary to thoroughly organize a special branch of the Survey with an efficient and adequate staff under a competent and distinct head. Proper organization will produce valuable results, and it will be money well spent if a certain sum be set aside annually for the support of a useful mining and mineralogical department. It has been argued by the Director that the present appropriation for the Geological Survey is not more than sufficient to carry

on strictly scientific work and research. If this be so it would not be unreasonable to expect the Minister of the Interior to ask Parliament for a special appropriation to defray the expense of conducting a mining and mineralogical department in the interest of the mining public.

We have refrained from commenting on the Morrison tariff bill for the reason that it must be clear to every one interested in the production of coal and iron ore in Canada that they would be benefited by reciprocity between the United States and this country in these two articles. We would of course be much pleased to hear that Mr. Morrison had succeeded in carrying his bill as originally presented to Congress, but we have felt at the same time that nothing we could say would convince those who have so strenuously opposed the bill that they would derive substantial benefit by removing the duty from foreign iron ore, and that we advocated its removal with a purely unselfish and disinterested motive. We prefer that our cause should be taken up by Mr. Morrison, Mr. Shriver, Secretary of the New York Metal Exchange, backed by Mr. Herbert W. Griffiths, Editor of the London (Eng.) *Iron Trade Exchange*, and other able champions of free trade; but, so far, these gentlemen have not been able to befriend us against such a powerful combination as the representatives of the iron ore industries of the Lake Superior region, supported by Mr. James M. Swank, of the *Bulletin* of the American Iron and Steel Association, Mr. Wilson Day, of the *Iron Trade Review* (Cleveland, O.) and other red-hot protectionists.

If it has been proved conclusively that the manufacture of iron cannot be profitably carried on in the provinces of Ontario and Quebec, and if the vast ore deposits of these two provinces are ever to become remunerative to their owners, something must be done towards developing them. There is a market in the United States for all the ore we can produce suitable for steel making, and at a price that should return a fair margin of profit to the miner. The present duty on iron ore imposed by the United States is not a prohibitory one for the higher grade ores, and by a reasonable expenditure in improving the handling and shipping facilities, the cost of transportation could be so reduced that the reduction from present freight rates would be sufficient to cover the duty. It is childish to sit and gaze at our extensive ore deposits and wait for reciprocity or removal of the duties from iron ore by the United States.

We are not disposed to admit that iron cannot be manufactured to great advantage in central Canada. The ore is, for the most part, such as few countries can boast of, and the deposits are surrounded by dense forests of wood suitable for charcoal, and limestone beds are close at hand. In the western and eastern provinces, British Columbia and Nova Scotia, the iron ore deposits and coal seams lie almost alongside each

other, yet, where in these provinces is iron profitably manufactured? The cause for this should be searched for until discovered and then overcome. Proper encouragement should be given to those who are disposed to work out the problem and are prepared to demonstrate that iron can be profitably manufactured in Canada, and such encouragement must come from the Government in the form of a bounty on pig and bar iron, and steel, for a term of years which will be equivalent to what would be considered a reasonable duty on the same, and when it had been conclusively demonstrated that Canada is capable of supplying her market with these articles of home manufacture, then let the bounty be withdrawn and a protective duty be imposed. In his budget speech this session the Finance Minister read to the House a list of articles, which, being raw material, as he described them, would be admitted free of duty. Pig iron appears on this list, and while we object to it being classed as raw material, we would not advocate a duty being levied on imported pig until such time as we are sure of a fair portion of our requirements being supplied by home manufacturers.

THE PHOSPHATE TRADE.

The annually increasing importance of this industry in Canada is very marked. Canadian phosphate has gained high favour amongst British manufacturers of superphosphate, and if the high standard of last year's shipments is maintained the demand for it will continue to rapidly increase. These assertions are emphatically endorsed by Mr. John Dyke, the Liverpool agent of the Department of Agriculture, who, in his annual report to the Minister of Agriculture, dated Liverpool, 31st December, 1885, says: "I have had a large number of enquiries from British and continental manufacturers in reference to Canadian phosphate, for which there is an annually increasing demand. Phosphate being a new but important interest in Canada, and destined to become one of the leading industries of the Dominion, I have obtained some special information on the subject from one of the leading merchants of England, and indeed of Europe, in this particular mineral. The shipments of phosphate during the past year from Canadian mines have been of an improved quality. The grade in percentage has been well maintained, even above the average, due chiefly to the greater care taken in dressing and cleaning before the ore has been milled. Previous to last year (1884) the percentage of the ore ran about 80 per cent. to 82 per cent., while some parcels received this year (1885) have come up to 85 or 86 per cent. of tribasic phosphate of lime. There is no reason why the regular output of Canadian phosphate, or, at any rate, a larger proportion of it, should not run to 85 per cent. It might be shipped continuously as pure as that, if proper care were taken in dressing and in separating it from foreign matter. The Canadian phosphate has, during the past few years, been in great favor amongst

manufacturers, and if producers can continue, and it is thought they can, to maintain the grade shipped during the past season, there is no reason why it should not take the lead of favour for prime phosphate. Although the volume of business done during the past year has been on the increase, and above the average, prices have receded, and closed 2d. per degree lower than they began the year, the ruling rate at the close of the season being 1s. for 75 per cent., with one-fifth of a penny rise. This price ruled for the last three months of the year, and it may be anticipated that if any change does take place it must be an advance.

With regard to ocean freights, the average for phosphate shipments from Montreal to London over the past season (1885) was 5s. 6d., having varied from 3s. to 7s. per ton. To Hamburg 12s. 6d. was the ruling rate."

Up to within a very recent date no definite action had been taken in Canada for the manufacture of superphosphate. Steps, however, have now been taken which may lead to the establishment of that industry. At the Basin du Lièvre, a point convenient to the mines, a mill has been erected, and is now in running order, for crushing, grinding and pulverizing the raw phosphate rock. A bolting apparatus is affixed to the machinery by which the pulverized material is reduced to an impalpable powder. This mill has a capacity equal to the production of forty tons per day, of ten hours, and to it there are blowers attached by use of which extraneous matter is separated. It is to be hoped that before long agriculturists in Canada will see the necessity of retaining in our own country a portion of the product of the mines, so valuable for renewing lands worn out by perpetual cropping.

THE MINES.

The mine which has attracted the most attention in the district during the past year is owned by the Dominion Phosphate company, and known as the "North Star." The Dominion company were the first to engage in deep mining in the phosphate deposits of Canada, and were actuated in doing so by a desire to prove a theory advanced by eminent scientists, including Prof. Wm. Boyd Hawkins, of Manchester, England, one of the leading geologists of the day, who, in 1884, visited the phosphate mines and did not hesitate to publish his opinion that at none of the mines visited by him had a sufficient depth been reached at which it should be expected that the main body of the deposits would be met with. His theory was that the larger bodies of ore would be found at depths varying from 300 to 1,000 feet below the surface. This theory has been practically proved correct. At the "North Star" mine the main shaft, from which upwards of 5,000 tons have been raised, has reached a depth of 300 feet, at which level it is penetrating a body of ore much larger than anything ever before met with in the district, and having the appearance of the main body of the deposit.

The "Union," "High Rock," "Emerald" and "Little Rapids," as well as the "North Star," mines, are producing high grade ore in large quantity and have already upwards of 14,000 tons awaiting shipment. This, together with the output of the McLaren & Blackburn mine in Templeton, and the

less important mines of the phosphate district makes a total of about 17,000 tons which has been mined since the close of navigation last year and is now ready for shipping. As we have already stated, more attention than formerly is being given to deep mining, and those who have so directed their operations have been much encouraged.

TRANSPORTATION OF ORE.

Among the important improvements which have recently been made for the more economical and expeditious transportation of ore, may be mentioned the completion of a tramway by the Phosphate of Lime company from their "High Rock" mine to the bank of the du Lièvre River. The company will begin to forward ore over the tramway early in May and will be enabled to deliver their entire output at point of shipment without interruption and at a much reduced cost. Five new ore scows have been launched since the ice left the du Lièvre river, and Messrs. Lomer, Rohr & Co. have put on another steam tug, the "Kate," which is the best boat now on the river. There are now a sufficient number of ore vessels to supply transport accommodation that will insure the delivery of the entire output of the mines at the railway terminus during the summer months.

Transportation of ore has not yet begun on the river on account of the unusual force of the spring freshet, and ore will not begin to move until the water has sufficiently receded, which is not likely to be the case before about the 10th of May.

GRINDING PHOSPHATE ROCK.

This is the first year that this branch of our phosphate industry has been engaged in. The Portland Phosphate Mining and Milling Company's mill at the Basin du Lièvre is now working and turning out about forty tons a day of ground phosphate. About 4,000 tons of the product of the mill have been contracted for by manufacturers of fertilizers in Chicago, Buffalo and Cleveland; the two former taking low grade and the latter the higher grade phosphate. It is not unlikely that the principal market for Canadian ground phosphate will be in the United States and that for sometime to come the lower grades will be most in demand, until manufacturers have come to appreciate the value of the high grade fertilizers such as can be produced from the better quality of Canadian phosphate rock.

The Portland M.M. & P. Co. have it in contemplation to erect sulphuric acid Works alongside their mill and to establish a factory for the manufacture of superphosphate in connection therewith. This company's operations will be watched with much interest, and it is to be hoped they will make a success of this new enterprise.

Phosphate Quotations.

It would appear from the most recent quotations received from abroad that Canadian phosphate rules in London and Liverpool at one shilling a unit for 80 per cent. mineral with a fifth of a penny rise, and in Hamburg at one shilling and five-eighths of a penny per unit with a fifth of a penny rise. This is not quite so good a price as was being offered at this date last season, but it will, nevertheless, admit of a very handsome margin of profit. One shilling a unit for 80 per cent., with a fifth of a penny rise, is equivalent to \$17.25 per ton for 80 per cent. and \$18.50 per ton for 85 per cent., delivered on board ship in Montreal, with freight between Montreal and Liverpool and London at the same rate which ruled last year.

Villeneuve Mica Mine.

The British and Canadian Mica and Mining Company are now systematically at work in their Villeneuve mine and are taking out a large amount of excellent mica, but owing to a scarcity of cutters a large quantity has accumulated which awaits being cut into plates and otherwise prepared for market. As this is the first mica mine which has been opened in the district the company have found it difficult to procure additional hands, experienced in cutting, cleaning, sorting and packing, to keep abreast of the output since the force of miners has been increased, and have been obliged to send to North Carolina for this description of skilled labour. Several men of long experience in the North Carolina mica mines have been engaged and are on their way to the Villeneuve mine. There is now a rapidly increasing demand for this mica, and the mine is capable of supplying all the consumers. The drifts and cross-cuts are developing some strong micaceous leads, carrying large and perfectly formed crystals, and it may be said that the mine is now being practically worked. The feldspar, one of the by-products of this mine, is of a very superior quality and commands a market value which is nearly sufficient to pay all the mining expenses. It is very white and quite free from iron, and has been pronounced suitable for the manufacture of porcelain. The British and Canadian Mica and Mining Company are to be congratulated on having acquired so valuable a property and on the satisfactory way it has developed since they became its proprietors and took possession.

MINERAL RESOURCES OF NOVA SCOTIA.

There are in this province extensive deposits of coal and iron ore, and her gold fields are increasing in importance with each year's development. Copper, manganese, antimony, barytes, gypsum, marble, etc., also occur in abundance, and the deposits have been worked to some extent. These resources are being gradually developed, and offer a promising field to the miner and capitalist.

The Inspector of Mines for Nova Scotia, in his annual report, recently published, gives a summary of the mineral production of the province for the year 1885, compared with that of the previous year, as follows:—

	1884	1885
Gold.....Ounces	16,079	22,203
Iron Ore.....Tons	54,885	48,129
Manganese Ore....."	302	353½
Copper....."	110
Lead....."	100
Barytes....."	300
Antimony....."	600	*758
Coal raised....."	1,389,295	1,352,205
Gypsum....."	111,068	87,644
Building stone....."	780	3,827
Coke made....."	40,085	30,185
Limestone....."	25,567	16,429
Grindstones, etc....."	2,200	2,208

* Amount exported.

COAL.

Nova Scotia coals belong entirely to the bituminous system of Dana, and may be sub-divided into coking, free burning and cannel coals. It may be remarked that the coals of this country belong to the same geological horizon of the carboniferous system as those of England and the Eastern United States, and present many points of intimate connection in fossil remains and in the associated strata.

The Sydney coal field occupies the eastern shore of Cape Breton County. Its land area is estimated at 200 square miles, and it now forms the rim of an extensive coal field extending under the Atlantic. Experience has proved that nearly all the seams can be followed in their subaqueous extension. Estimates based on the system of enquiry adopted by the Royal Commission on the duration of the coal supply of Great Britain, put the amount of available coal in these submarine areas, after making proper deductions for waste, etc., at not less than 2,000,000,000 tons. The amount of available coal contained in the seams now opened in this district, in the areas leased for the purpose of working them, is estimated at 212,000,000 tons. This estimate does not include the coal in the seams which are unopened in the land areas in operation, nor the value of the seams in the leases which are at present awaiting a favorable opportunity for development, which items would swell the coal supply of this district to figures representing many years' output greatly exceeding any yet obtained.

The following analyses show the general character of the seams of the district:—

COMPOSITION.	NAME OF SEAM.		
	Sidney.	Phalen.	Harbor.
Moisture	1-260	921	80
Vol. Comb. Matt. Fast Coking	35-514	30-312	29-40
Fixed Carbon	59-111	62-334	65-50
Vol. Comb. Matt. Slow Coking	33-840	28-625	27-85
Fixed Carbon	60-785	64-021	67-05
Ash	4-115	6-433	4-30
Sulphur	1-705	1-105	1-29
Theo. Evaporative power	8-33	8-78	9-19

The Springhill coal field lies north of the Cobequid mountains, in Cumberland County, the northern edge of which has been traced from the Joggins shore of Cumberland basin, about 18 miles, to the Styles mine, but its deflection to the south to join the Springhill coal mines district has not been followed. On the southern or Springhill side of the basin there is a large and important development of coal seams. The productive measures stretch for many miles in a westerly direction to the Cumberland basin at Apple river, but have not yet been prospected. The chief development has been at Springhill by the Cumberland Railway and Coal Company, whose output is now at the rate of 350,000 tons per annum, and is largely used for steam purposes on Canadian railways, steamboats, etc. The coal is also adapted for domestic purposes, and its coke is extensively used at the Londonderry iron works.

The following analyses show the quality of the coal of this district:—

CONTENTS.	North Seam.	Main Seam.	South Seam.
Moisture	1-625	78	1-39
Vol. Comb. Matt.	28-672	31-32	31-32
Fixed Carbon	65-431	62-54	61-58
Ash	4-272	5-34	5-79
Sulphur	783	1-38	80
Evaporative power	8-99	8-46

The extent of country underlain by the productive measures is not yet clearly known, but has been estimated at 300 square miles. The district is intersected by the Intercolonial Railway, and a branch railway runs from the Springhill collieries to Parrsboro, on the Bay of Fundy, where extensive shipping docks are being constructed.

The principal collieries now in operation, and the respective output of each for 1885, are as follows:

Name of Colliery.	Situation.	Output for 1885.
		Tons.
Chignecto	Cumberland County.	6,084
Joggins	" ..	17,664
Minudie	" ..	7,702
Springhill	" ..	335,055
Acadia	Pictou County	98,150
Albion	" ..	129,195
Intercolonial	" ..	109,139
Vale	" ..	76,125
Sydney	Cape Breton County.	124,274
Victoria	" ..	47,614
Liugan	" ..	21,761
Reserve	" ..	83,276
International	" ..	67,959
Bridgeport	" ..	13,178
Little Glace Bay	" ..	39,400
Caledonia	" ..	58,859
Block House	" ..	11,075
Gowrie	" ..	74,414
Unimportant collieries		31,281
Total		1,352,205

The sales of Nova Scotia coal for 1885 were as follows:—

	Tons.
Provinces of Nova Scotia	444,652
New Brunswick	148,634
Newfoundland	74,322
Prince Edward Island	52,770
Quebec	493,917
West Indies	5,732
United States	34,483
Total (long tons)	1,254,510

(To be Continued.)

Improved Hoisting Engines.

We have received the most recently published catalogue of the Lidgerwood Manufacturing Company, whose extensive works are in Brooklyn, N.Y., and offices and salesrooms in New York city and Boston. This company are manufacturers of the most modern high-speed hoisting engines, and boilers, for marine service, contractors, miners and railway corporations. A great variety of their engines are illustrated by beautifully finished engravings, and are fully described in the catalogue. All the work of this company is done on the *duplicate part system*, enabling them to fill orders promptly for duplicate parts, which are made to gauge and will fit without trouble. Their system for testing is very complete, and all engines are run with steam on before being shipped, and boilers are thoroughly tested by steam, as well as by the usual hydrostatic test. As will be seen by their advertisement in another column, this company give special attention to engines for mining purposes, and will furnish estimates, &c., on application.

Gold Mining in British Columbia.

The official annual report of the Minister of Mines for 1885 shows a falling off in the year's production of \$22,427 from that of 1884, and the statistics show a large increase in the number of miners engaged in gold mining in some of the gold districts of the province. The total amount of gold known to have been exported by banks, etc., amounted to \$594,782 for the year, and the amount estimated to have been carried away in private hands \$118,956,

making a total yield of \$713,738, as against \$736,165 for 1884. The number of miners employed during the year was 2,902 and the average yearly earnings per man was \$246, as against 1,858 miners employed in 1884 with an average yearly earning of \$396 per man. The decrease in the average yearly earnings is accounted for by the rush to Granite Creek towards the close of the mining season, and by an increased number of Chinamen rocking during the autumn months on the bars of the Fraser (already worked and re-worked) with but little return for their labour. The statistics show that the increase in the number of miners occurred chiefly in the Yale district, where towards the close of the season there were 998 at work, and the year's yield of gold was only \$146,500. This had the effect of reducing the general average earning for the year, but as nearly nine-tenths of the miners did not reach the diggings in the district until shortly before the season closed, it is reasonable to suppose that next year the total yield from the Yale district will be largely in excess of these figures, and that the general average earning for the province will be increased in like proportion.

The Gold Commissioner of Cariboo states that in his district another year passed without any material development of the quartz ledges, and with the exception of the efforts put forth by the Quesnelle Quartz Mining Company, nothing had been attempted in this direction. The Quesnelle company were, he states, making a most laudable attempt to prove the value of their mine at Hixon Creek and had purchased an engine and other machinery at San Francisco and engaged the services of experienced Californian quartz miners. The Commissioner estimates the gold yield of the district for 1885 to have been \$347,700, and adds that Cariboo has not as yet derived any benefit from railway construction. Freight rates are still high, and Cariboo prices have undergone but little change during the year.

GRANITE CREEK.

This stream, to which there has been a great rush, is a tributary of the Tulaneen, or north fork of the Similkameen, and falls into that river on its right bank, about twelve miles above its junction with the South Similkameen at Princeton—better known as the "Vermillion Forks," and "Allison's." About five miles from its mouth Granite Creek is joined by a small creek from the south-west, which point is called the "Forks." With the exception of a few hundred yards at its mouth, Granite Creek runs from the forks downwards in a deep V shaped gorge, through which the yearly freshet, evidently of great volume, has washed everything except the gold and some gravel—in fact this portion of the creek has been ground sluiced by nature. Mr. T. Elwyn, Deputy Provincial Secretary, visited Granite Creek last autumn, and reports that from near its mouth to a point something over half a mile below the "Forks," a distance of about four miles, no claim which has been tested on either side of the bed of the stream has failed to yield good returns, the ground for that distance averaging over an ounce a day to the hand. On 31st October, on lower Granite Creek, there were 62 companies owning creek claims, averaging probably 300 feet to the company, who were working. Of these, 34 were taking out gold and 28 either preparing to do so or prospecting. The gold admitted to have been taken out by the several white and Chinese companies, from 5th July to 31st October, 1885, amounted to \$90,000, which, considering the great loss of time caused by the freshet, and the difficulty of obtaining lumber

for sluice-boxes, is a creditable showing. On the morning of November 1st one company washed up \$750, the result of the labour of eight men for thirty hours. Mr. Elwyn believes that the discoveries on Granite Creek will lead to the opening up of an extensive gold field which will be of more benefit to the province than any yet discovered, except, perhaps, Cariboo. He states that he was particularly impressed with the fact that those who were warmest in praise of these new diggings were amongst the most experienced miners who had gone into the district.

CANADA'S IRON TRADE.

We are indebted to the publishers, Messrs. Dawson Bros., of Montreal, for a copy of a very interesting work entitled "The Manufacture, Consumption and Production of Iron, Steel and Coal in the Dominion of Canada, with some notes on the manufacture of iron, and on the iron trade, in other countries." Mr. James Herbert Bartlett, Associate Member of the Institute of Civil Engineers, &c., &c., &c., the author of this work, is deserving of much praise for the careful manner in which he has compiled the information it contains. The author's aim has been to bring into prominent notice the importance to the Dominion of Canada of the manufacture of iron within her borders, and to show how this industry would benefit the country and develop her resources. The subject suggests many important questions which are ably dealt with by the author, whose researches in the direction of statistical detail have been of an exhaustive character, and it is evident no pains have been spared in tabulating the same in an intelligent and comprehensive manner. Mr. Bartlett appears to appreciate the fact that reliable, practical information in connection with the manufacture of iron in Canada has been much needed, and, in treating the subject from a commercial rather than from a scientific point of view, he points out the conditions under which other nations have succeeded and gives the value of the manufactured articles imported into Canada and the quantities consumed.

Statistics of the imports and exports of iron and the manufactures thereof have been compiled from the Dominion Trade and Navigation Returns, and show that the value of the imports, including duty paid thereon, for the seventeen years since Confederation—1869-1884, inclusive—has reached the enormous sum of \$252,638,613.44, or an average of about \$14,860,000 a year. The classification and tabulation of statistics in connection with the various branches of the iron and steel industries represent a remarkable amount of patience and perseverance on the part of the author and have been so arranged by him as to be easily available for reference. As a statistical work the book will prove very valuable, and besides being replete with interesting and useful information it will undoubtedly draw attention to the very important subjects on which it treats. The book reflects great credit on the author and we feel ourselves much indebted to Mr. Bartlett for having put into our hands so much information in so concise a form.

In the Smithsonian Institution at Washington is the small nugget of gold, a little larger than a pea, that first met the eyes of James Marshall in the sawmill raceway at Sacramento, and was the beginning of those discoveries in California that have added nearly \$1,500,000,000 in gold to the world's stock of the precious metals.

CANADA —AT THE— COLONIAL & INDIAN EXHIBITION. Her Natural History, Mineral & Fisheries Exhibit.

In the west transept of the exhibition building at South Kensington, will be found the collection of natural history specimens, which must prove to visitors one of the leading features of the Canadian display. The Canadian Geological and Natural History Survey has, in itself, enough to form a separate display, though supplementary to it are the Hudson's Bay, the Renfrew and Hubbard collections, thus representing adequately the whole game of the Dominion. The centre of this west transept is, correspondingly with the east transept, occupied by a commanding trophy of game and game birds, and even those of the migratory class, arranged with no little tact and judgment. From this point the west gallery is reached. *Here the mineral resources of Canada are set out in full array. So rapid has been the growth of the mining industries of the Dominion during the past decade, that the 549 specimens exhibited at Philadelphia have increased to 725 at South Kensington, contributions coming in large numbers and great variety from the mines of Nova Scotia, New Brunswick, Quebec, Ontario, the North-West and British Columbia, and including many specimens of considerable value shown in the process of various dressings from the simple ore. The practical results likely to follow from this mineral exhibit are considerable. One may, perhaps, be not too sanguine in anticipating that so powerful a witness to Canada's vast and rich mineral deposits will even do much to overcome the prejudice of English capitalists against embarking in enterprise in this direction—a prejudice not altogether unnatural, when one remembers the hands into which some Canadian mining ventures have fallen in recent years. Intimate knowledge, such as the present exhibit will encourage, must, however, bring about a different state of things.* In the west gallery the shafting provided will be used for the display of machinery in motion—always an interesting feature to visitors. Here the skilfully-designed agricultural and general products of the Birmingham of Eastern Canada will undoubtedly be the object of much curiosity to English mechanics, agriculturalists and manufacturers. Beyond the west gallery is the west arcade, in which Canada has been provided with some 2,000 feet for the display of the products of her fisheries. The exhibit made in London three years ago is here brought into requisition, with, of course, large additions of stuffed and preserved specimens of fishes and marine invertebrata, as well as schooners, models of salmon hatcheries, fishing tackle and all utensils for sea and lake fishing. The National Fish Culture Association is taking charge of the oval until a fitting receptacle is ready for it. An interesting feature of this part of the Canadian display will be the intended shipment of fish periodically, from Canadian waters, under the refrigerator process, not for sale, but to demonstrate the practicability of direct shipments of the fish of Ontario, Manitoba and British Columbia by direct Canadian rail to the Atlantic port, and thence to England.—*Canadian Gazette, London, Eng.*

The Drum Lamont mine of Montana distinguished itself during January by the largest production on record. Sixty stamps working thirty days crushed 3,456 tons, yielding \$100,831.19.

Notes on the Progress of Mining and Metallurgy in Europe.

BY E. J. BALL, PH. D.

(Assistant in Metallurgy at the Normal School of Science and Royal School of Mines, London.)

Written specially for the Canadian Mining Review.

The action of coal-dust in colliery explosions continues to excite considerable discussion, notwithstanding the attention it has already received, and R. Schneider, in remarking on the results of some experiments made at the Segen-Gottes Colliery, Moravia, which showed in direct opposition to those obtained in Dr. Hilt's experiments with dust from the same colliery in the Neunkirchen level—that free-lying dynamite would always explode the Segen-Gottes dust—states that Dr. Hilt suggested that this was probably due to the detonators that were used being too weak, and to their consequently not exploding the dynamite properly, and that it would be therefore well to repeat the experiments with the triple force detonators manufactured by A. Barnhardt, of Brunswick. This was done, but the results were the same as before, the dust being exploded every time without any gas being present. Schneider is consequently of opinion that the difference in the results of the experiments made at the colliery and at Neunkirchen were due to the excessively fiery nature of the dust, which, he considers, must either have been damp or not sufficiently powdered when used in the trials at Neunkirchen. The general conclusions derived from his experiments have, however, tended to confirm those obtained by Dr. Hilt, and attention is drawn to the fact that in all cases where dry and dusty fiery pits are worked the present method of shot firing cannot possibly be practised without danger.

In referring to the investigation recently made at the Gabriel Colliery in the Karwin district, Austria, on the influence of the changes in barometric pressure on the escape of fire-damp, the results of which confirmed those obtained in previous experiments, showing that the danger increased with a falling barometer, J. Mayer remarks that although this may be true in some respects, the chief danger lies in accumulations of coal-dust.

J. Haller has described the method of treatment adopted in working the brown-coal deposit at Liescha, Austria, which is 25 feet thick, and he states that the one originally employed—stopping—caused the ventilation to be so bad, and the temperature so high, that it was abandoned, and a modified post and stall work introduced in its stead. The result was that not only was the ventilation greatly improved, but the work done per man and per shift increased by 39 per cent. The drawing engines in the pit were, until two years ago, worked by steam brought down to them in pipes; this has now been replaced by compressed air with very satisfactory results. The wooden timberings, which had to withstand considerable pressure, and, in consequence, to be frequently renewed at certain places, has been replaced by steel rails, and although their first cost is greatly in excess of that of the wood, they have proved in the long run much more economical.

With regard to the sinking of shafts, J. H. Poetsch has taken out additional patents in Germany, and elsewhere, in which he proposes to employ the pipes he has used in freezing the quicksand through which it was desired to sink the shaft, after it has been sunk and the ground thawed again, either in connection with pumps to partially remove the water or as supports by

filling them with cement, or by otherwise strengthening them.

H. Thomas, of the French Geological Survey, discusses in the *Génie Civil*, the size of the pillars which should be left to support the roof in underground workings, and he gives some figures relating to building stone, calculated from the resistance offered by the materials to crushing stress.

The mineral wealth of Spain is exceedingly great, and its natural advantages are such, that should the country ever succeed in obtaining a settled form of government, its mineral resources are sure to receive considerable attention, and this tends to endow the description by R. A. de Yarza of the mineral deposits of the Province of Guipúzcoa (*Revista Minera of Metalúrgica*, 1886, Jan. 17 and Jan. 24) with considerable interest. The ores found are chiefly those of lead, zinc and iron, as although copper ore has been found it has only been in small quantities, and up to the present is of no importance. No coal beds have been discovered, but some lignite deposits exist in the cretaceous rocks. The galena occurs principally in lodes in palæozoic measures, those occurring in the cretaceous being of far less importance. Zinc blende is also found both in the palæozoic and cretaceous rocks, and calamine also occurs in considerable quantities. Iron ore deposits are abundant, and would be of great importance were they not so close to those of Biscaya, with which it will be difficult for them to compete successfully. The ores, which are of good quality, occur partly as contact deposits between granite and palæozoic rocks, partly in the palæozoic rocks themselves, and occasionally also in the cretaceous.

H. Tweddle describes in *Engineering* the petroleum regions of Europe and Asia, and he states that they extend from the north-western extremity of Great Britain diagonally across Europe, the Crimea, and the Caucasus, and that they terminate in Central Asia. This zone embraces nearly all England and Scotland south of the Grampians, Hanover, Bohemia, Galicia, Moldavia, Roumania, Transylvania and Hungary, the Crimea, the Caucasus chain, and in the trans-Caspian regions, the Island of Tchelenken, Krasnovodsk, the Neft Gora, the Heri Rud, and Tashkent, the last explored petroleum region in Central Asia. He remarks on the great similarity of the geological measures where petroleum is known principally to exist, viz., in the cretaceous, though it is found in every formation from the granite and volcanic rocks to the highest and most recent deposits of the Aral-Caspian, and he considers that the zone may fairly be regarded as more or less similar to the petroleum fields of North America. These, it may be mentioned, have been recently described at considerable length by C. Zincken, of Leipzig, Germany.

Turning from mining to the kindred subject metallurgy, the iron and steel industry first claims attention. The chief object of discussion at present is as to the relative advantages of large and small Bessemer converters, and it would seem to be the general opinion, that however advantageous small converters may be under certain conditions, yet, that under ordinary circumstances, it will be impossible for them to compete successfully with large ones.

The basic process is making rapid progress on the continent of Europe, but the progress is somewhat slower in Great Britain, where the abundance of pure ore renders it unnecessary to work deposits of ore which are of lesser purity. Magnesite is coming into considerable use in the manufacture of basic bricks.

Arrangements for the collection of the waste products from coke ovens are gradually being

made use of in the case of those already constructed, and a considerable number of the more modern forms of ovens have been lately erected, the tendency being to employ almost solely horizontal ovens of the modified Coppée type. Compressing the coal by means of rollers after charging, has, it is stated, enabled, in the case of certain German coal, a much better coke to be produced than would otherwise have resulted. It appears to be generally considered that the collection of the ammonia from the waste gases of blast furnaces using coke as fuel is not likely to prove very profitable.

The Manhès process for the Bessemerizing of copper regulus is assuming considerable importance, and the latest form of converter proposed by Manhès, and exhibited by him at the Antwerp Exhibition, resembles in shape the boiler of a horizontal engine. It is cylindrical, and rests on a truck. The tuyère box runs along the side, and holes in its back facing each tuyère permit of rods being inserted through them to keep the nozzles free. The converter is revolved by means of a tooth-wheel and gearing, and the throat is in the centre of the upper portion.

Electrolytic processes are also making considerable advance, though their progress has not been so rapid as was at one time anticipated, the chief reason being that the comparative abundance of fuel and of skilled labor renders it impossible for processes which rely chiefly on the saving effected in these respects at the expense of time to compete with others which enable the capital invested to be turned over far more rapidly. In the case of copper, too, although electrolysis enables the gold and silver present in the material treated to be collected, and a metal to be produced which commands a higher price in the market, still the great majority of the ores contain such small percentages of the precious metals that they, and the higher value of the copper produced, would not compensate for the loss of interest on the capital invested. In countries, however, where fuel is either scarce or costly, and labor expensive and unskilled, electrolytic processes certainly deserve a far greater consideration than they usually receive, more especially in such places where water-power can be made use of, or where the materials to be treated contain an appreciable amount of the precious metals. Electrolytic plants for the treatment of cupriferous materials are, however, being built in various parts of Europe. There are several in the United Kingdom, and they chiefly use metallic anodes, concentrating the silver and gold in "bottoms," which are afterwards cast into the desired shape; anodes of regulus have also been tried, but, I believe, without marked success, although works have recently been erected at Stolberg, in Austria, and in the neighborhood of Genoa, where regulus alone is intended to be used.

Scarcely any attention has been paid in Europe to the employment of electrolysis in the case of lead, but attention is beginning to be directed to its use in the case of zinc ores, though I am unacquainted with any works employing as yet such a process on a commercial scale.

Very many different types of dynamos are in use at works, and in choosing one it seems customary to select that which converts the greatest percentage of energy into electricity; but, however correct this may be from the point of view of an electrician, from that of a metallurgist this perfection of the machine should be by no means the sole consideration, as simplicity of construction and the ease with which repairs can be carried out should receive careful consideration, more especially in such cases where the position of the works will render it impossible

to obtain skilled assistance in case of a breakdown, and where the machine will have to be entrusted to persons who, it may be, have had no experience in its management, and who are wanting theoretical knowledge. Of course no machine should be chosen unless it gave fair results, but I lay stress on the advisability of it being as simple as possible in construction, as this is very frequently overlooked, and my attention was drawn to the subject in the Works where I studied the process.

Two or three adoptions of electricity to the treatment of gold ores have been more or less discussed of late, but opinion is still very much divided as to their merits.

Numerous so-called improved forms of amalgamators, &c., have been proposed, but most appear worthless, and the great majority of the others have scarcely advanced beyond the patent stage.

CORRESPONDENCE.

MINING RECORDS.

Editor Canadian Mining Review.

Experience in the old world may be of use in the new. In Ireland, the earliest written record I can find is one A. M. 3656, and since then they are few and far between. There are, however, other records, in the old attics and other waste heaps; but who were the miners? and when were they worked? or what they did, underground it is impossible to say. The latter is even the case with works carried on within the present century, not a record having been kept except in a few cases, and if an adventurer starts a mine in or near an old sett, he has to take chances, while after he has come on a good lode and made all preparations for working a mine, he may find that the "old men" have been before him and cut out all "the riches." This has been the case over and over again in our modern mining operations; "old men's workings" have spoiled many a good mine. Yet what can be done? Out of the thousands of mines that, from time to time, have been in operation in Ireland, I believe there are not the records of fifty, if of half that number.

I read with great interest the evidence given before the Enquiry held some times since in Ottawa, and had a fellow feeling with the geologists examined, as no matter how zealous, anxious or painstaking a geologist may be, unless he has the power to say—stand and deliver! he cannot get records from unwilling hands.

At the present time, according to the new act, mining agents must annually return records of their working—but not of old workings which are those of most importance in connection with further research. During the last 30 years or more, I have been endeavouring to get copies of these old plans and sections, and in no important mine have I perfectly succeeded. In some few small workings I was able to do so, but invariably in the large ones I was unsuccessful. In most cases the mines had gone through different hands, and at each successive sale of the property, the sellers had either kept back or destroyed all records, except those that they considered advantageous to themselves; consequently to get full plans and sections would necessitate expensive surveys that the company or I could not undertake—or the agent or company might be unwilling to allow the extent of the works to be made public—they might let you look at the plans and sections and say you might copy them, but invariably I found it hard to accomplish the latter,

and never without an amount of tact. When an agent pretends to be willing and at the same time intends to prevent you getting copies of his plans, it takes a great deal of stratagem to circumvent him.

These are my experiences. Some agents cannot give statistics unless he went to great expense in new surveys, while others will not, as they are afraid it might possibly be hereafter detrimental to their interest. To get statistics, therefore, it is necessary to make it compulsory that plans and sections of all mining operations should be furnished to an authorized official, as otherwise no one, no matter how energetic or painstaking, can procure them. The great losses due to unrecorded mines in the "old countries," British and foreign, ought to be a lesson to the new, and teach them to "take time by the forelock." Let them have properly appointed officers whose duty it is to record all mining operations, and to whom all statistics of such operations must be given. In a new country this could be easily managed by insisting on all mining adventures being registered. The register fee might or rather ought to be merely nominal, but coupled with it should be an obligation to furnish, at specified times, full accounts of all mining operations, the neglect of complying with the latter subjecting them to severe penalties. Such a law would not prevent individual research, while it would protect subsequent adventures and the losses so often due to bogus companies.

J. HENRY KINAHAN.

NOVA SCOTIA GOLD FIELDS.

PAY-STREAKS.

Editor Canadian Mining Review.

Not having had the advantages of a personal knowledge of the "Pay-Streaks," I was led, from the descriptions that I had seen, to suppose they were the filling in of vertical shrinkage fissures. Mr. Gilpin's very instructive description of them in March number of the REVIEW, however, seems to suggest that they are the shrinkage fissures on the arch of an anticlinal curve, dipping or "hading" more or less at a high angle at the line of axis of that curve; and these in each district in accordance with the strike of the line of axis, occur in local systems having similar strikes and underlie, the strikes being parallel to the line of axis. If this is the case the fissure ought invariably to decrease in width gradually in depth; the decrease in width being more gradual the more perpendicular the streak—that is, the less the angle between the dip of the streak and the vertical of the axis of the curve, the less the variations in the width of the fissure—that is, the fissures at or near the crown of the arch of the curve, ought to be more uniform in width as followed down than if away from the line of the crown of the arch; the farther from the crown the greater the opening at the surface. This can be seen in sharply folded strata, the quartz veins filling such shrinkage fissures when nearly perpendicular thinning very gradually, while, if underlying at lower angles, the change in their widths is much more rapid. If "Pay-Streaks," are the filling in of fissures of this class they must die out in depth and finally end. There is, however, the converse to this: What are the shrinkage fissures in the sides of a synclinal curve? Ought they to open in depth? Is the tension in the strata forming the anticlinal curve similar to the tension in the strata forming the synclinal curve? Of the latter, however,

I cannot speak, as my experience has never furnished an example.

NORTH SHORE MINES.

LAKE SUPERIOR DISTRICT.

Editor Canadian Mining Review,

SIR,—Seeing in your valuable paper for frequent accounts of the tests at the silver mines in this district, also at the Huronian Mine in the gold region, during the past year, I think a word would not be out of place respecting some of the silver mines upon this shore which were worked more or less twelve years ago.

I speak as a miner who worked in most of the mines mentioned below, and can vouch for the facts in each case.

I will first take the "Silver Harbour" mine. The main shaft at this mine was sunk 120 feet, and another some 30 feet. There was a large amount of black sulphide of silver and silver ore taken out, sufficient, if the mine had been properly handled, to pay working expenses; and when the work was stopped the mine looked well, so much so that an American gentleman would have worked it right along if he could have procured the property on reasonable terms and without restrictions. The company who worked this mine literally squandered their money by erecting a splendid building, which cost some fabulous sum, and was wholly unnecessary; they also spent a large amount for engines and machinery for stamp-mill, which were never used and subsequently went to ruin, instead of opening up and testing their mine at the outset—which has never been done. It is my belief that had the company been mining men, or their manager a practical mining man, this mine would be working and paying large dividends at the present day.

I will next take the "3 A" mine, which is upon the adjoining location to "Silver Harbour," but a distinct vein. The main shaft is down 140 feet, and another about 40 feet. There was a large amount of native silver and nickel silver taken out at this mine; certainly some of the largest specimens of native silver ever taken out on the North Shore were from "3 A," and there was a very fair show of silver when work was suspended. "3 A" may be classed with "Silver Harbour" as regards mismanagement, for there was sufficient silver taken out to pay all expenses and leave a handsome balance had it been properly taken care of.

Should the owners of either "Silver Harbour" or "3 A" mines place their properties upon the market as assessable stock, I am assured the people in this district would readily take them up.

At "Thunder Bay" mine there was only one shaft sunk, about 100 feet in depth, from which a large amount of native silver was taken out, sufficient to pay working expenses if the mine had been worked economically; but here again the company incurred the expense of valuable machinery and stamp-mill, which were afterwards left to ruin, before proving their mine in any way. It is my opinion that should a strong company take hold of this mine and have it thoroughly tested it would turn out well.

"Jarvis Island" was worked and tested to a depth of 130 feet, and found to carry some native silver and silver ore, and when abandoned there was a good show of silver. The

owner of this property intends, I believe, to start work again this spring.

"Spar Island" has not been worked for some 40 years, though it is said to be one of the best mines on this shore. The main vein carries grey copper ore and native silver, a large amount of each, and is 12 feet wide; there is also another vein four feet wide. Some few years ago a gentleman in Port Arthur, who has the control of this estate, had some very fine specimens taken out. The vein shows equally good upon the mainland.

The only mine which has in any sense been tested in this district is "The Duncan." The main shaft was sunk 900 feet, and another shaft 150 feet; the longest drift is 400 feet. The company was a good one, the best upon this shore to the present day, and for 700 feet along vein from main shaft the mine was very fairly tested. They obtained a large quantity of native silver for about 400 feet upon surface, and considerable at a depth of 100 feet, and the core from diamond drill usually assayed silver wherever tested upon vein. The testing upon this 700 feet of the main vein was considerable, but the company did no work or exploring except upon this one vein, although there are several others upon the location all carrying good mineral. It has been reported that a large deposit of silver has recently been discovered upon the location by one of the men who previously worked at this mine.

All the above mines are easy of access, either water, road or rail facilities being excellent, and there are numerous other locations around this district which could be profitably worked under efficient and economical management.

There is no doubt that the owners of the properties in the new silver district and gold region have taken warning from the previous experiences of mining upon this shore and have gone to no unnecessary expense until assured of an adequate supply of mineral to pay for expensive buildings and machinery; but as I see in your paper that capital is seeking investment in mines and mineral lands, I am sure it would amply repay the capitalist to visit and take note of the mines above mentioned, in addition to the new mines which are being opened up all around us.

Yours truly,
"A MINER."

Port Arthur,
Lake Superior.

FOSSIL HUMAN FOOTPRINTS.—Herr H. E. Low has obtained and forwarded to the Imperial Museum in Vienna twelve large stone slabs bearing the foot-prints discovered last year in the solid rock in the quarry over Lake Managua, in the territory of Nicaragua. The interest was increased by the statement that those foot-prints had been overlain by eleven different layers of stone, extending to a depth of four meters, and indicating an antiquity for our race quite transcending all conjectures hitherto hazarded. They are about three quarters of a meter square. They can now be inspected by European geologists. The foot-prints are sunk into the stone to a depth of from eight to ten centimeters. The stone itself is a porous tufa, and the superincumbent layers, which had been removed for building purposes, were all of a more or less solid volcanic conglomerate. The foot-prints are very conspicuous, and seem to be those of three distinct persons, one of whom was a child.

The proprietor of Montvale Springs in Blomet County, Tenn., has sunk a shaft ninety feet deep on his property and claims to have found a rich vein of silver ore.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

Mineralogy of Pliny.

To a student who is following a course of science and literature, many questions of strange interest present themselves. In his scientific studies, on the one hand he becomes aware of the latest discoveries of the day; he is perfectly acquainted with the physical structure of the globe, and seems as conversant with what is written in the records of nature, as the book-worm is with the productions of his favorite author. On the other hand, his literary pursuits transport him into the far past, into the ages of antiquity, and bring before him the simplicity of men of by-gone days, with their odd superstitions and quaint beliefs. He cannot fail to remark the striking contrast between the opinions of the most intelligent and learned of the ancients, and those of the mere student of science of our day.

To exemplify this general idea, we may consider a particular case. See what difference there exists between the knowledge which we have to-day of mineralogy and that which the ancients possessed. A mineralogist who has been so happy as to fall in with Pliny's treatise of mineralogy cannot fail to be amused. During the days when Pliny flourished, a scientist was far different from what he is at present. Whatever was known at Pliny's time, Pliny knew; and whatever Pliny knew is to be found in his admirable works. By reading this author, therefore, we can have an adequate knowledge of what the ancients knew, and in Pliny we can study the light in which mineralogy was once regarded.

Five lengthy books of his "Natural History" are devoted to minerals. But, gentle reader, were you to peruse a work on moral philosophy or a volume of rhetoric, you would then know nearly as much mineralogy as you would after the perusal of Pliny's dissertations.

What, indeed, are these five books if not mere rhetorical dissertations, replete with moral reflections? Admirably written, indeed, his works cannot fail to interest. He has paid great attention to his style and choice of words. He discourses on the ill effects of gold and silver and of the precious stones, and does not hesitate to denounce them as the bane of Roman society. He is loud in his lamentations because of the introduction of these "articles of luxury," the cause of effeminacy, the corrupter of morals. This is his unceasing strain while he is speaking of gold, and occasionally he is strong in his invectives against the unknown inventor of such and such a perfidy.

In the first of his five books he treats of metals, beginning with gold. After a severe criticism of Roman luxury, we are presented with a complete history of rings, then of crowns, and lastly of gold coin, the invention of which "was an enormous crime against humanity." A slight allusion to the ductibility of gold and the manner of procuring this metal is what comes nearest to the subject of mineralogy. Read what he says about silver, and you have a good idea of ancient mirrors, vases, plates and statues of silver. Read his second book, on copper, and you have a perfect knowledge of bronze statues and chandeliers. We must not

omit medicine; this is a strong point in Pliny's works. He delights in dwelling on the medicinal properties of the metals, most of which were used for that purpose in his time. In fact, iron and lead are scarcely treated under any other head.

The third book is an excellent treatise on painting; the fourth is devoted to marble sculpture, while the fifth treats of precious stones. This is by far the most useful part of Pliny's work. He displays in it a wonderfully extensive knowledge of the gems which had become at that time very extensively used in Roman society. It is needless to state that, in a strictly mineralogical sense, his vast erudition fails to give even a clue to the science of gems. His classification is entirely artificial. Gems which, for instance, are varieties of quartz are given as totally different species; whilst others, widely different in composition and crystallographic characters, are brought together with regard solely to their external properties. But we are inclined to be indulgent towards the old Roman *savant* when we consider the amount of invaluable information he imparts and the graceful diction he employs, and we willingly admit that science would soon become popular if all scientists could and would imitate Pliny's attractive style.

W. A. H.

Aluminum.

"The metal of the future" is the designation given to aluminum by the President of the Scranton Board of Trade, in an address before that body. Possessing all the good qualities of iron without its weakness, it will, he thinks, in time totally replace that, at present, most useful of metals. Aluminum is now principally used in alloys. But its resistance to oxidation eminently fits it for household utensils, its lightness compared with its bulk makes it very suitable for architectural purposes, and its use in building steamships, and furnishing railways with their rolling stock, would revolutionize present rates of travel. It is a much better conductor than iron, and would replace that metal in telegraph wires; knives, swords and axes made of alloys of aluminum receive a much better temper than the finest steel. The great objection to the use of this metal, which is so abundantly diffused, has hitherto been the cost of reducing it from its ores. But President Price asserts that the price of aluminum is now only \$15 a pound, which is 50% less than it was thirty years ago; and a company in Cleveland claims that within the past year, by a new process, they have made it possible to reduce the price to \$4 a pound. If aluminum really possesses all these qualities in such a high degree, we may indeed prepare to witness new achievements, which will throw those already accomplished into the shade.

D. PHALEN.

Germanium.

Prof. Clemens Winkler, writing in a recent number of *Nature*, announces the discovery of a new element by himself. In the summer of 1885 a new mineral was discovered at Himmelsfurst, near Freiberg, in Saxony. This mineral was a rich silver ore, and received the name of *argyrodite*. Before the blow-pipe it yielded sulphur, silver, and a little mercury, in the following percentage: mercury 0.21 per cent., silver 73 to 75 per cent., sulphur 17 to 18 per cent. A small quantity of iron and traces of arsenic were also present. But there was always 6 or 7 per cent. un-

accounted for. Prof. Winkler claims to have discovered that this portion of the mineral contains a new element, which, in honor of his country, he has named *Germanium*. Germanium resembles antimony in its properties. The presence of arsenic and antimony in the minerals accompanying argyrodite made the discovery of the new element very difficult. On heating argyrodite in a current of hydrogen a black, crystalline and moderately volatile sublimate is formed, consisting of the sulphides of germanium and mercury. Germanium sulphide dissolves in ammonium sulphide and is precipitated in a pure state by hydrochloric acid. On heating germanium sulphide in a current of air, or warming it with nitric acid, a white oxide, non-volatile at a red heat, is produced. This oxide is readily reduced by hydrogen, but the reduction of the sulphide is more difficult on account of its volatility. Germanium, like arsenic, has a grey colour, and a moderate lustre. It is volatile only at a full red heat, but much less so than antimony. Its crystals could not be mistaken for those of the latter metal. The atomic weight of germanium, when ascertained, will show whether this element is to occupy the vacant place in the periodic system between antimony and bismuth.

COAL GAS.—It has been lately discovered that the heat value of coal gas has been rated too high, up to the present. A French chemist has ascertained that the real heat value is 15 per cent. below what it was thought to be, or 5,200 instead of 6,000 calories per cubic meter at 0°.

TIN.—Some of the supposed causes of the disintegration of tin are discussed in the *Mining and Scientific Press*. The idea of a dimorphesin is suggested by the fact that the disaggregated tin is of a lesser specific gravity than was the tin in its former state. The presence of mercury in the metal is another possible cause of its disintegration.

GEMS.—The *Jewelers' Journal* gives the following chemical directions for making artificial gems. To make the *sapphire*, heat 4 oz. of aluminum oxide and 4 oz. of red lead to a red heat. When smelted add 10 grs. bichromate of potassium and 17 grs. cobalt oxide. Stir up well and keep cool. The *ruby* is produced by the following process: Heat 4 oz. of aluminum oxide and 4 oz. of red lead to the smelting point, and add from 7 to 16 grs. of potassium bichromate. For the *emerald*, to the same quantity of oxide of aluminum and red lead, add from 8 to 12 grains of sodium uranite, and treat as above. Parisian or Alaska *diamonds* are made by heating 65 per cent. of pulverized crystal quartz, 20 per cent. of red lead, 8 per cent. of pure carbonate of potash, 5 per cent. of boric acid, and 2 per cent. of white arsenic. The brilliancy of the diamonds depends upon the purity of the red lead and of the carbonate of potash.

COPPER AND NITROGEN.—M. Blendlot, of the French Academy of Sciences, has observed a curious phenomenon with respect to the action of nitrogen on copper. A disk of platinum and a disk of copper, 0.03 meter in diameter, were placed 3 or 4 millimeters apart, under a bell jar of porcelain open below, and were fixed vertically in front of each other by means of platinum stands. The whole apparatus was then heated for three hours by a gas furnace.

At the end of that time, although there had been no electric current, the face of the platinum disk was found blackened with a deposit containing copper and platinum. In short, the copper had crossed over to the platinum. By repeating the experiment in a different gas, M. Blendlot ascertained that the nitrogen of the air had been the agent of the transfer by combining with the copper, which it afterwards deposited on the platinum.

MELDOMETER.—Prof. Joly, of Trinity College, Dublin, has described, in *Nature*, an apparatus contrived by himself, by which he can determine or compose the melting points of minerals, and their behaviour at high temperatures, either alone or in the presence of reagents. To this apparatus, which is to be attached to a mineralogical microscope, he gives the name of meldometer. He says, "As I now use it, it consists of a narrow ribbon of platinum (2 mm. wide), arranged to traverse the field of the microscope. The ribbon, clamped in two brass clamps so as to be readily removable, passes bridgewise over a little scooped-out hollow in a disk of ebony (4 cm. diam). The clamps also take wires from a battery (3 grooves cells), and are adjustable; the resistance being placed in circuit, the strip can be raised in temperature to the melting point of platinum." The platinum strip is placed in the field of a 1" objective, and a wedge of tainted glass is used in photometrically estimating the temperatures, by extinguishing the field. Approximate estimations of the temperature are made in terms of the resistance of the platinum strip. These observations may be compared with the readings on the wedge, which are then used for ready determinations. The mineral is placed in small fragments near the centre of the platinum strip, and the current increased till the melting point is apparent. By means of this apparatus, Prof. Joly has melted beryl, orthoclase, and quartz, and discovered for the first time that the last fuses below the melting point of platinum.

BEAUTIFUL MARBLES IN ALGIERS.—The re-discovery of the ancient quarries where the beautiful antique marbles were obtained is interesting. An extensive quarry, covering two thousand acres, has been quite recently discovered in the province of Oran, near the Mediterranean coast, in Algiers. The deposit has been obtained by an Italian who has constructed roads and begun operations. The deposit contains giallo antico, breccia, and cipoline, besides black and white marble. These fine colored stones can be laid on the wharf at Oran for about one dollar a cubic foot. The beautiful yellow marble, giallo antico, has, until this late re-discovery, been unknown, save by the fragments found in Roman ruins two or three years ago.

AN IMPORTANT EXPERIMENT.—The mining public will be much interested in the results obtained from the experiments which are to be made by means of a dynamo to be set up on the Truckee river in Nevada to transmit thence the whole motive power of that stream—furnished by a Laffel turbine, with a full head of water, with 100 feet fall—to a receiving dynamo at Virginia City. Those engaged in this operation claim that in this way a motive power can be furnished at Virginia City for a hundred-stamp mill for \$200. At present, the daily cost of transporting Constock ores from the mines to the mills on Carson river is \$1,000, nearly all of which will be saved by having the mills directly at the mines.

NOVA SCOTIA.

Considerable attention is now being directed to Lunenburg county as a promising gold field.

The Empress mine in Renfrew district produced 284 ounces of gold during the month of March.

Miners have been working on tribute at the Mount Uniacke mines and have been earning about \$75 per month per man.

It is stated that a rich streak has been struck in the Rawdon mines, and that one thousand ounces of gold were taken from it during the first two weeks of March.

The first clean up at the Crow's Nest mine, in the Sherbrooke district, Gaysborough county, showed a yield of 75 ounces of fine gold from 37 tons of quartz put through the mill.

At the Antimony Mines at West Gore, Hants County, two inclined shafts and one perpendicular have been sunk. The ore is at present hoisted by horse power, but it is the intention of the owners to put in steam hoisting gear. Forty men are now employed in the mine, and their number will be increased to 60 or 70. 100 tons of ore, valued at from \$50 to \$55 a ton, are shipped monthly to England via Halifax.

Those interested in the development of the gold mines of this province are anxious that the local government should incur the expense of sinking a shaft to the depth of 1000 or 1200 feet for the purpose of proving the continuity or recurrence of the "pay-streaks" in quartz veins. As no practical test has yet been made, and as there is good reason to believe that deep mining would pay, it is not unreasonable to ask for government aid in settling the question. The government receives a royalty on all the gold mined in the province, and would, therefore, be warranted in incurring the expense of so practical a test, in view of the possibilities which might result therefrom.

ONTARIO.

(Thunder Bay District.)

It has been reported that the miners at *Rabbit Mountain* have come upon a very rich vein, but the report has not been verified.

At the *Huronian* mine the shaft is now down 200 feet and at this level the vein is six feet wide, and producing ore that mills \$20 a ton.

A mica deposit, situated about fifty miles west of Port Arthur, will probably be developed this Spring and its actual value ascertained.

At the East end of Silver Mountain a branch vein is being followed alongside the main one. It carries rich ore and is eighteen inches wide.

Steam drills, air compressors and miscellaneous machinery, arrived at the *Beaver* mine in March, and are probably in working order by this time.

Some fine ore is now in sight at *Silver Falls* mine but the work of development is not being driven as actively as the location deserves.

The main vein has been reached at East End Silver Mountain mine. It shows very rich and work is being vigorously pushed ahead.

Work is progressing favourably at *Crown Point* mine and the promising character of the ore warrants continued efforts being made towards further development.

The site on which the mill for the *Beaver* mine is to be erected is on Silver creek, in a position convenient to the *Beaver* and *Silver Creek* mines, and a tramway has already been located thereto.

Mr. Richard Crow has been engaged to operate the mill at the *Beaver* mine. This gentleman was employed last year by the *Huronian* Gold Mining Company, and proved himself a competent mill man.

Preparations have been in progress to open up four mining locations in Black Bay country along the line of the Canadian Pacific railway, between Loon Lake and Black Sturgeon river. These include three argentiferous galena veins.

BRITISH COLUMBIA.

About six miles of McGulloch creek is available for mining and it is thought several hundred miners will make good pay there during the coming season.

A large amount of eastern capital is finding its way into Big Bend country, and it is expected that the placer and quartz claims will be vigorously worked.

The Homestake company, who are working on the Tulameen fifteen miles above Granite creek, took out \$523 in gold for three days work the last week in March.

Until the water lowers in the creeks of the Semilkameen district it will be impossible to resume mining operations, and this is not looked for until the end of May, or later.

Mining on Granite Creek received a check in the beginning of April. Work had been in progress for some weeks when a warm spell caused a freshet, necessitating the suspension of mining for an indefinite time.

Camp creek, Cairn creek, French creek, Gold creek and McCulloch creek, in the Big Bend district, will be worked to some extent this season, and it is expected a lively camp will spring up near the mouth of McCulloch creek.

It was expected that bed-rock would be reached about May 1st on the Barrett claim which is located on McCulloch Creek, higher up than the Ophir Bed-Rock Flume Company's. The tunnel is in 600 feet.

Mr. D. Jordan, of San Francisco, who recently purchased a tract of coal lands contiguous to the Wellington mines, has been superintending the sinking of prospecting bores and the extension of the slope. He is well satisfied with the result of these operations up to the present time.

In accounting for the failures in quartz mining in the Cariboo district heretofore, it is said to be due to improper treatment of the pyritous quartz which is said to carry \$20 to the ton in

finely disseminated gold locked up in the sulphuret and which has been worked as free milling ore. Thus, for the want of concentrating machinery, the pyrites passed off, carrying the gold with it.

At a public meeting in Farwell in February it was decided to petition the Local Government to aid in improving the means of communication between the Big Bend mines and Farwell, including the construction of a waggon road from La Porte to Ground Hog Basin, at the head of McCulloch's Creek, so as to facilitate the transportation of machinery and supplies to the various mining camps.

The Ophir Bed-Rock Flume Company propose constructing a flume the entire length of their ground which extends for a mile and a half along McCulloch Creek, in the Big Bend district. Into this will be hydrauliced the gravel for 100 feet in width down to bed-rock, 60 feet below the surface. The flume will be seven feet wide, through which it is intended that 1000 yards of earth will pass each twenty-four hours. The gravel prospects ten cents to the pan.

UNITED STATES.

Colorado is credited with a bullion product for 1885 of \$22,800,000, of which \$13,000,000 was silver, \$5,000,000 gold, \$4,000,000 lead, and \$500,000 copper.

The Ropes gold mine, Michigan, for the month of February, produced from bullion and concentrates, about \$3,000 in precious metal, averaging about \$6.50 per ton of rock treated.

The shipments of last season from the Quincy mine, Mich., to Detroit smelters, aggregated 7,091,765 pounds of mineral which yielded about 82.47 per cent., or 5,848,197 pounds, of refined copper, and gave a mining profit of \$229,895.45.

**MINING REGULATIONS**

To Govern the Disposal of

Mineral Lands other than Coal Lands.**1886.**

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed twenty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labour during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES, AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, &c., &c.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

A. M. BURGESS,

Deputy Minister of the Interior.

THE INTERCOLONIAL RAILWAY OF CANADA. and Freight Route,

BETWEEN

CANADA AND GREAT BRITAIN, AND

direct route between the West and all points on the Lower St. Lawrence and Baie des Chaleurs, also New Brunswick, Nova Scotia, Prince Edward Island, Cape Breton, Newfoundland, Bermuda, and Jamaica.

New and elegant Pullman Buffet Sleeping and day cars run on through Express trains. Passengers for Great Britain or the Continent, by leaving Toronto at 8.30 A.M. Thursday, will join Mail Steamer at Halifax A.M. Saturday.

Superior Elevator, Warehouse and Dock accommodation at Halifax for shipment of grain and general merchandise.

Years of experience have proved the Intercolonial in connection with Steamship lines to and from London, Liverpool and Glasgow to Halifax, to be the quickest freight route between Canada and Great Britain.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with,—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein,—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section,—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers", is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,

Commissioner.

NOTICE.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Indian Supplies" will be received at this office up to noon of TUESDAY, 20th APRIL, 1886, for the delivery of Indian Supplies during the fiscal year ending 30th June, 1887, consisting of Flour, Bacon, Beef, Groceries, Ammunition, Twine, Oxen, Cows, Bulls, Agricultural Implements, Tools, etc., duty paid at various points in Manitoba and the North-west Territories.

Forms of Tender, giving full particulars relative to the Supplies required, dates of delivery, &c., may be had by applying to the undersigned, or to the Indian Commissioner at Regina, or to the Indian Office, Winnipeg.

Parties may tender for each description of goods (or for any portion of each description of goods) separately or for all the goods called for in the Schedules.

Each tender must be accompanied by an accepted Cheque in favour of the Superintendent General of Indian Affairs on a Canadian Bank for at least five per cent. of the amount of the tenders for Manitoba and the North-west Territories, which will be forfeited if the party tendering declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted the cheque will be returned.

Tenders must make up in the Money columns in the Schedule the total money value of the goods they offer to supply, or their tender will not be entertained.

Each tender must, in addition to the signature of the tenderer, be signed by two sureties acceptable to the Department, for the proper performance of the contract.

In all cases where transportation may be only partial by rail, contractors must make proper arrangements for supplies to be forwarded at once from railway stations to their destination in the Government Warehouse at the point of delivery.

The lowest or any tender not necessarily accepted.

L. VANKOUGHNET,

Deputy of the Superintendent-General
of Indian Affairs.

Dept. of Indian Affairs,
Ottawa, 3rd March, 1886.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

We understand a start has been made towards preparing a statistical report of Canadian mines, and while we welcome this information we would express the hope that this very important work will be proceeded with without interruption.

It now looks as though the collection and publication of mining statistics will receive some attention from the Geological Survey, but we fear the staff which has been told off for this special work, with the meagre assistance at its command for collecting and compiling statistics, is quite inadequate to do justice to this important work. The ability of Messrs. Coste and Ingall, the two Mining Geologists of the Survey, to whom this special work has been assigned, is not brought into question, but it is unreasonable to expect that these two gentlemen, in addition to performing their professional duties in the field, as heretofore, can organize and conduct the mining and mineralogical branch of the Survey, and collect and compile statistics in connection therewith in a manner that will do themselves justice or satisfy the mining public. If the information that this work is to supply is to be of any value it must be full and complete. That it may be so, it will be necessary to thoroughly organize a special branch of the Survey with an efficient and adequate staff under a competent and distinct head. Proper organization will produce valuable results, and it will be money well spent if a certain sum be set aside annually for the support of a useful mining and mineralogical department. It has been argued by the Director that the present appropriation for the Geological Survey is not more than sufficient to carry

on strictly scientific work and research. If this be so it would not be unreasonable to expect the Minister of the Interior to ask Parliament for a special appropriation to defray the expense of conducting a mining and mineralogical department in the interest of the mining public.

We have refrained from commenting on the Morrison tariff bill for the reason that it must be clear to every one interested in the production of coal and iron ore in Canada that they would be benefited by reciprocity between the United States and this country in these two articles. We would of course be much pleased to hear that Mr. Morrison had succeeded in carrying his bill as originally presented to Congress, but we have felt at the same time that nothing we could say would convince those who have so strenuously opposed the bill that they would derive substantial benefit by removing the duty from foreign iron ore, and that we advocated its removal with a purely unselfish and disinterested motive. We prefer that our cause should be taken up by Mr. Morrison, Mr. Shriver, Secretary of the New York Metal Exchange, backed by Mr. Herbert W. Griffiths, Editor of the London (Eng.) *Iron Trade Exchange*, and other able champions of free trade; but, so far, these gentlemen have not been able to befriend us against such a powerful combination as the representatives of the iron ore industries of the Lake Superior region, supported by Mr. James M. Swank, of the *Bulletin of the American Iron and Steel Association*, Mr. Wilson Day, of the *Iron Trade Review* (Cleveland, O.) and other red-hot protectionists.

If it has been proved conclusively that the manufacture of iron cannot be profitably carried on in the provinces of Ontario and Quebec, and if the vast ore deposits of these two provinces are ever to become remunerative to their owners, something must be done towards developing them. There is a market in the United States for all the ore we can produce suitable for steel making, and at a price that should return a fair margin of profit to the miner. The present duty on iron ore imposed by the United States is not a prohibitory one for the higher grade ores, and by a reasonable expenditure in improving the handling and shipping facilities, the cost of transportation could be so reduced that the reduction from present freight rates would be sufficient to cover the duty. It is childish to sit and gaze at our extensive ore deposits and wait for reciprocity or removal of the duties from iron ore by the United States.

We are not disposed to admit that iron cannot be manufactured to great advantage in central Canada. The ore is, for the most part, such as few countries can boast of, and the deposits are surrounded by dense forests of wood suitable for charcoal, and limestone beds are close at hand. In the western and eastern provinces, British Columbia and Nova Scotia, the iron ore deposits and coal seams lie almost alongside each

other, yet, where in these provinces is iron profitably manufactured? The cause for this should be searched for until discovered and then overcome. Proper encouragement should be given to those who are disposed to work out the problem and are prepared to demonstrate that iron can be profitably manufactured in Canada, and such encouragement must come from the Government in the form of a bounty on pig and bar iron, and steel, for a term of years which will be equivalent to what would be considered a reasonable duty on the same, and when it had been conclusively demonstrated that Canada is capable of supplying her market with these articles of home manufacture, then let the bounty be withdrawn and a protective duty be imposed. In his budget speech this session the Finance Minister read to the House a list of articles, which, being raw material, as he described them, would be admitted free of duty. Pig iron appears on this list, and while we object to it being classed as raw material, we would not advocate a duty being levied on imported pig until such time as we are sure of a fair portion of our requirements being supplied by home manufacturers.

THE PHOSPHATE TRADE.

The annually increasing importance of this industry in Canada is very marked. Canadian phosphate has gained high favour amongst British manufacturers of superphosphate, and if the high standard of last year's shipments is maintained the demand for it will continue to rapidly increase. These assertions are emphatically endorsed by Mr. John Dyke, the Liverpool agent of the Department of Agriculture, who, in his annual report to the Minister of Agriculture, dated Liverpool, 31st December, 1885, says: "I have had a large number of enquiries from British and continental manufacturers in reference to Canadian phosphate, for which there is an annually increasing demand. Phosphate being a new but important interest in Canada, and destined to become one of the leading industries of the Dominion, I have obtained some special information on the subject from one of the leading merchants of England, and indeed of Europe, in this particular mineral. The shipments of phosphate during the past year from Canadian mines have been of an improved quality. The grade in percentage has been well maintained, even above the average, due chiefly to the greater care taken in dressing and cleaning before the ore has been milled. Previous to last year (1884) the percentage of the ore ran about 80 per cent. to 82 per cent., while some parcels received this year (1885) have come up to 85 or 86 per cent. of tribasic phosphate of lime. There is no reason why the regular output of Canadian phosphate, or, at any rate, a larger proportion of it, should not run to 85 per cent. It might be shipped continuously as pure as that, if proper care were taken in dressing and in separating it from foreign matter. The Canadian phosphate has, during the past few years, been in great favor amongst

manufacturers, and if producers can continue, and it is thought they can, to maintain the grade shipped during the past season, there is no reason why it should not take the lead of favour for prime phosphate. Although the volume of business done during the past year has been on the increase, and above the average, prices have receded, and closed 2d. per degree lower than they began the year, the ruling rate at the close of the season being 1s. for 75 per cent., with one-fifth of a penny rise. This price ruled for the last three months of the year, and it may be anticipated that if any change does take place it must be an advance.

With regard to ocean freights, the average for phosphate shipments from Montreal to London over the past season (1885) was 5s. 6d, having varied from 3s. to 7s. per ton. To Hamburg 12s. 6d. was the ruling rate."

Up to within a very recent date no definite action had been taken in Canada for the manufacture of superphosphate. Steps, however, have now been taken which may lead to the establishment of that industry. At the Basin du Lièvre, a point convenient to the mines, a mill has been erected, and is now in running order, for crushing, grinding and pulverizing the raw phosphate rock. A bolting apparatus is affixed to the machinery by which the pulverized material is reduced to an impalpable powder. This mill has a capacity equal to the production of forty tons per day, of ten hours, and to it there are blowers attached by use of which extraneous matter is separated. It is to be hoped that before long agriculturists in Canada will see the necessity of retaining in our own country a portion of the product of the mines, so valuable for renewing lands worn out by perpetual cropping.

THE MINES.

The mine which has attracted the most attention in the district during the past year is owned by the Dominion Phosphate company, and known as the "North Star." The Dominion company were the first to engage in deep mining in the phosphate deposits of Canada, and were actuated in doing so by a desire to prove a theory advanced by eminent scietists, including Prof. Wm. Boyd Hawkins, of Manchester, England, one of the leading geologists of the day, who, in 1884, visited the phosphate mines and did not hesitate to publish his opinion that at none of the mines visited by him had a sufficient depth been reached at which it should be expected that the main body of the deposits would we met with. His theory was that the larger bodies of ore would be found at depths varying from 300 to 1,000 feet below the surface. This theory has been practically proved correct. At the "North Star" mine the main shaft, from which upwards of 5,000 tons have been raised, has reached a depth of 300 feet, at which level it is penetrating a body of ore much larger than anything ever before met with in the district, and having the appearance of the main body of the deposit.

The "Union," "High Rock," "Emerald" and "Little Rapids," as well as the "North Star," mines, are producing high grade ore in large quantity and have already upwards of 14,000 tons awaiting shipment. This, together with the output of the McLaren & Blackburn mine in Templeton, and the

less important mines of the phosphate district makes a total of about 17,000 tons which has been mined since the close of navigation last year and is now ready for shipping. As we have already stated, more attention than formerly is being given to deep mining, and those who have so directed their operations have been much encouraged.

TRANSPORTATION OF ORE.

Among the important improvements which have recently been made for the more economical and expeditious transportation of ore, may be mentioned the completion of a tramway by the Phosphate of Lime company from their "High Rock" mine to the bank of the du Lièvre River. The company will begin to ferward ore over the tramway early in May and will be enabled to deliver their entire output at point of shipment without interruption and at a much reduced cost. Five new ore scows have been launched since the ice left the du Lièvre river, and Messrs. Lomer, Rolir & Co, have put on another steam tug, the "Kate," which is the best boat now on the river. There are now a sufficient number of ore vessels to supply transport accommodation that will insure the delivery of the entire output of the mines at the railway terminus during the summer months.

Transportation of ore has not yet begun on the river on account of the unusual force of the spring fieshet, and ore will not begin to move until the water has sufficiently receded, which is not likely to be the case before about the 10th of May.

GRINDING PHOSPHATE ROCK.

This is the first year that this branch of our phosphate industry has been engaged in. The Portland Phosphate Mining and Milling Company's mill at the Basin du Lièvre is now working and turning out about forty tons a day of ground phosphate. About 4,000 tons of the product of the mill have been contracted for by manufacturers of fertilizers in Chicago, Buffalo and Cleveland; the two former taking low grade and the latter the higher grade phosphate. It is not unlikely that the principal market for Canadian ground phosphate will be in the United States and that for sometime to come the lower grades will be most in demand, until manufacturers have come to appreciate the value of the high grade fertilizers such as can be produced from the better quality of Canadian phosphate rock.

The Portland M.M. & P. Co. have it in contemplation to erect sulphuric acid Works alongside their mill and to establish a factory for the manufacture of superphosphate in connection therewith. This company's operations will be watched with much interest, and it is to be hoped they will make a success of this new enterprise.

Phosphate Quotations.

It would appear from the most recent quotations received from abroad that Canadian phosphate rules in London and Liverpool at one shilling a unit for 80 per cent. mineral with a fifth of a penny rise, and in Hamburg at one shilling and five-eighths of a penny per unit with a fifth of a penny rise. This is not quite so good a price as was being offered at this date last season, but it will, nevertheless, admit of a very handsome margin of profit. One shilling a unit for 80 per cent., with a fifth of a penny rise, is equivalent to \$17.25 per ton for 80 per cent. and \$18.50 per ton for 85 per cent., delivered on board ship in Montreal, with freight between Montreal and Liverpool and London at the same rate which ruled last year.

Villeneuve Mica Mine.

The British and Canadian Mica and Mining Company are now systematically at work in their Villeneuve mine and are taking out a large amount of excellent mica, but owing to a scarcity of cutters a large quantity has accumulated which awaits being cut into plates and otherwise prepared for market. As this is the first mica mine which has been opened in the district the company have found it difficult to procure additional hands, experienced in cutting, cleaning, sorting and packing, to keep abreast of the output since the force of miners has been increased, and have been obliged to send to North Carolina for this description of skilled labour. Several men of long experience in the North Carolina mica mines have been engaged and are on their way to the Villeneuve mine. There is now a rapidly increasing demand for this mica, and the mine is capable of supplying all the consumers. The drifts and cross-cuts are developing some strong micaceous leads, carrying large and perfectly formed crystals, and it may be said that the mine is now being practically worked. The feldspar, one of the by-products of this mine, is of a very superior quality and commands a market value which is nearly sufficient to pay all the mining expenses. It is very white and quite free from iron, and has been pronounced suitable for the manufacture of porcelain. The British and Canadian Mica and Mining Company are to be congratulated on having acquired so valuable a property and on the satisfactory way it has developed since they became its proprietors and took possession.

MINERAL RESOURCES OF NOVA SCOTIA.

There are in this province extensive deposits of coal and iron ore, and her gold fields are increasing in importance with each year's development. Copper, manganese, antimony, barytes, gypsum, marble, etc., also occur in abundance, and the deposits have been worked to some extent. These resources are being gradually developed, and offer a promising field to the miner and capitalist.

The Inspector of Mines for Nova Scotia, in his annual report, recently published, gives a summary of the mineral production of the province for the year 1885, compared with that of the previous year, as follows:—

	1884	1885
Gold.....Ounces	16,079	22,203
Iron Ore.....Tons	54,885	48,129
Manganese Ore....."	302	353½
Copper....."	110
Lead....."	100
Barytes....."	300
Antimony....."	600	*758
Coal raised....."	1,389,295	1,352,205
Gypsum....."	111,068	87,644
Building stone....."	780	3,827
Coke made....."	40,085	30,185
Limestone....."	25,567	16,429
Grindstones, etc....."	2,200	2,208

* Amount exported.

COAL.

Nova Scotia coals belong entirely to the bituminous system of Dana, and may be sub-divided into coking, free burning and cannel coals. It may be remarked that the coals of this country belong to the same geological horizon of the carboniferous system as those of England and the Eastern United States, and present many points of intimate connection in fossil remains and in the associated strata.

The Sydney coal field occupies the eastern shore of Cape Breton County. Its land area is estimated at 200 square miles, and it now forms the rim of an extensive coal field extending under the Atlantic. Experience has proved that nearly all the seams can be followed in their subaqueous extension. Estimates based on the system of enquiry adopted by the Royal Commission on the duration of the coal supply of Great Britain, put the amount of available coal in these submarine areas, after making proper deductions for waste, etc., at not less than 2,000,000,000 tons. The amount of available coal contained in the seams now opened in this district, in the areas leased for the purpose of working them, is estimated at 212,000,000 tons. This estimate does not include the coal in the seams which are unopened in the land areas in operation, nor the value of the seams in the leases which are at present awaiting a favorable opportunity for development, which items would swell the coal supply of this district to figures representing many years' output greatly exceeding any yet obtained.

The following analyses show the general character of the seams of the district:—

COMPOSITION.	NAME OF SEAM.		
	Sidney.	Phalen.	Harbor.
Moisture	1.260	.921	.80
Vol. Comb. Matt. Fast Coking	35.514	30.312	29.40
Fixed Carbon	59.111	62.334	65.50
Vol. Comb. Matt. Slow Coking	33.840	28.625	27.85
Fixed Carbon	60.785	64.021	67.05
Ash	4.115	6.433	4.30
Sulphur	1.705	1.105	1.29
Theo. Evaporative power	8.33	8.78	9.19

The Springhill coal field lies north of the Cobequid mountains, in Cumberland County, the northern edge of which has been traced from the Joggins shore of Cumberland basin, about 18 miles, to the Styles mine, but its deflection to the south to join the Springhill coal mines district has not been followed. On the southern or Springhill side of the basin there is a large and important development of coal seams. The productive measures stretch for many miles in a westerly direction to the Cumberland basin at Apple river, but have not yet been prospected. The chief development has been at Springhill by the Cumberland Railway and Coal Company, whose output is now at the rate of 350,000 tons per annum. and is largely used for steam purposes on Canadian railways, steamboats, etc. The coal is also adapted for domestic purposes, and its coke is extensively used at the Londonderry iron works.

The following analyses show the quality of the coal of this district:—

CONTENTS.	North Seam.		
	North Seam.	Main Seam.	South Seam.
Moisture	1.625	.78	1.39
Vol. Comb. Matt.	28.672	31.32	31.32
Fixed Carbon	65.431	62.54	61.58
Ash	4.272	5.34	5.79
Sulphur783	1.38	.80
Evaporative power	8.99	8.46

The extent of country underlaid by the productive measures is not yet clearly known, but has been estimated at 300 square miles. The district is intersected by the Intercolonial Railway, and a branch railway runs from the Springhill collieries to Parrsboro, on the Bay of Fundy, where extensive shipping docks are being constructed.

The principal collieries now in operation, and the respective output of each for 1885, are as follows:

Name of Colliery.	Situation.	Output for 1885.
		Tons.
Chignecto	Cumberland County.	6,084
Joggins	"	17,664
Minudie	"	7,702
Springhill	"	335,055
Acadia	Pictou County.	98,150
Albion	"	129,195
Intercolonial	"	109,139
Vale	"	76,125
Sydney	Cape Breton County.	124,274
Victoria	"	47,614
Lingan	"	21,761
Reserve	"	83,276
International	"	67,959
Bridgeport	"	13,178
Little Glace Bay	"	39,400
Caledonia	"	58,859
Block House	"	11,075
Gowrie	"	74,414
		1,320,924
Unimportant collieries		31,281
Total		1,352,205

The sales of Nova Scotia coal for 1885 were as follows:—

	Tons.
Provinces of Nova Scotia	444,652
New Brunswick	148,634
Newfoundland	74,322
Prince Edward Island	52,770
Quebec	493,917
West Indies	5,732
United States	34,483
Total (long tons)	1,254,510

(To be Continued.)

Improved Hoisting Engines.

We have received the most recently published catalogue of the Lidgerwood Manufacturing Company, whose extensive works are in Brooklyn, N.Y., and offices and salesrooms in New York city and Boston. This company are manufacturers of the most modern high-speed hoisting engines, and boilers, for marine service, contractors, miners and railway corporations. A great variety of their engines are illustrated by beautifully finished engravings, and are fully described in the catalogue. All the work of this company is done on the *duplicate part system*, enabling them to fill orders promptly for duplicate parts, which are made to gauge and will fit without trouble. Their system for testing is very complete, and all engines are run with steam on before being shipped, and boilers are thoroughly tested by steam, as well as by the usual hydrostatic test. As will be seen by their advertisement in another column, this company give special attention to engines for mining purposes, and will furnish estimates, &c., on application.

Gold Mining in British Columbia.

The official annual report of the Minister of Mines for 1885 shows a falling off in the year's production of \$22,427 from that of 1884, and the statistics show a large increase in the number of miners engaged in gold mining in some of the gold districts of the province. The total amount of gold known to have been exported by banks, etc., amounted to \$594,782 for the year, and the amount estimated to have been carried away in private hands \$118,956,

making a total yield of \$713,738, as against \$736,165 for 1884. The number of miners employed during the year was 2,902 and the average yearly earnings per man was \$246, as against 1,858 miners employed in 1884 with an average yearly earning of \$396 per man. The decrease in the average yearly earnings is accounted for by the rush to Granite Creek towards the close of the mining season, and by an increased number of Chinamen working during the autumn months on the bars of the Fraser (already worked and re-worked) with but little return for their labour. The statistics show that the increase in the number of miners occurred chiefly in the Yale district, where towards the close of the season there were 998 at work, and the year's yield of gold was only \$146,500. This had the effect of reducing the general average earning for the year, but as nearly nine-tenths of the miners did not reach the diggings in the district until shortly before the season closed, it is reasonable to suppose that next year the total yield from the Yale district will be largely in excess of these figures, and that the general average earning for the province will be increased in like proportion.

The Gold Commissioner of Cariboo states that in his district another year passed without any material development of the quartz ledges, and with the exception of the efforts put forth by the Quesnelle Quartz Mining Company, nothing had been attempted in this direction. The Quesnelle company were, he states, making a most laudable attempt to prove the value of their mine at Hixon Creek and had purchased an engine and other machinery at San Francisco and engaged the services of experienced Californian quartz miners. The Commissioner estimates the gold yield of the district for 1885 to have been \$347,700, and adds that Cariboo has not as yet derived any benefit from railway construction. Freight rates are still high, and Cariboo prices have undergone but little change during the year.

GRANITE CREEK.

This stream, to which there has been a great rush, is a tributary of the Tulaneen, or north fork of the Similkameen, and falls into that river on its right bank, about twelve miles above its junction with the South Similkameen at Princeton—better known as the "Vermillion Forks," and "Allison's." About five miles from its mouth Granite Creek is joined by a small creek from the south-west, which point is called the "Forks." With the exception of a few hundred yards at its mouth, Granite Creek runs from the forks downwards in a deep V shaped gorge, through which the yearly freshet, evidently of great volume, has washed everything except the gold and some gravel—in fact this portion of the creek has been ground sluiced by nature. Mr. T. Elwyn, Deputy Provincial Secretary, visited Granite Creek last autumn, and reports that from near its mouth to a point something over half a mile below the "Forks," a distance of about four miles, no claim which has been tested on either side of the bed of the stream has failed to yield good returns, the ground for that distance averaging over an ounce a day to the hand. On 31st October, on lower Granite Creek, there were 62 companies owning creek claims, averaging probably 300 feet to the company, who were working. Of these, 34 were taking out gold and 28 either preparing to do so or prospecting. The gold admitted to have been taken out by the several white and Chinese companies, from 5th July to 31st October, 1885, amounted to \$90,000, which, considering the great loss of time caused by the freshet, and the difficulty of obtaining lumber

for sluice-boxes, is a creditable showing. On the morning of November 1st one company washed up \$750, the result of the labour of eight men for thirty hours. Mr. Elwyn believes that the discoveries on Granite Creek will lead to the opening up of an extensive gold field which will be of more benefit to the province than any yet discovered, except, perhaps, Cariboo. He states that he was particularly impressed with the fact that those who were warmest in praise of these new diggings were amongst the most experienced miners who had gone into the district.

CANADA'S IRON TRADE.

We are indebted to the publishers, Messrs. Dawson Bros., of Montreal, for a copy of a very interesting work entitled "The Manufacture, Consumption and Production of Iron, Steel and Coal in the Dominion of Canada, with some notes on the manufacture of iron, and on the iron trade, in other countries." Mr. James Herbert Bartlett, Associate Member of the Institute of Civil Engineers, &c., &c., the author of this work, is deserving of much praise for the careful manner in which he has compiled the information it contains. The author's aim has been to bring into prominent notice the importance to the Dominion of Canada of the manufacture of iron within her borders, and to show how this industry would benefit the country and develop her resources. The subject suggests many important questions which are ably dealt with by the author, whose researches in the direction of statistical detail have been of an exhaustive character, and it is evident no pains have been spared in tabulating the same in an intelligent and comprehensive manner. Mr. Bartlett appears to appreciate the fact that reliable, practical information in connection with the manufacture of iron in Canada has been much needed, and, in treating the subject from a commercial rather than from a scientific point of view, he points out the conditions under which other nations have succeeded and gives the value of the manufactured articles imported into Canada and the quantities consumed.

Statistics of the imports and exports of iron and the manufactures thereof have been compiled from the Dominion Trade and Navigation Returns, and show that the value of the imports, including duty paid thereon, for the seventeen years since Confederation—1869-1884, inclusive—has reached the enormous sum of \$252,638,613.44, or an average of about \$14,860,000 a year. The classification and tabulation of statistics in connection with the various branches of the iron and steel industries represent a remarkable amount of patience and perseverance on the part of the author and have been so arranged by him as to be easily available for reference. As a statistical work the book will prove very valuable, and besides being replete with interesting and useful information it will undoubtedly draw attention to the very important subjects on which it treats. The book reflects great credit on the author and we feel ourselves much indebted to Mr. Bartlett for having put into our hands so much information in so concise a form.

In the Smithsonian Institution at Washington is the small nugget of gold, a little larger than a pea, that first met the eyes of James Marshall in the sawmill raceway at Sacramento, and was the beginning of those discoveries in California that have added nearly \$1,500,000,000 in gold to the world's stock of the precious metals.

CANADA —AT THE— COLONIAL & INDIAN EXHIBITION.

Her Natural History, Mineral & Fisheries Exhibit.

In the west transept of the exhibition building at South Kensington, will be found the collection of natural history specimens, which must prove to visitors one of the leading features of the Canadian display. The Canadian Geological and Natural History Survey has, in itself, enough to form a separate display, though supplementary to it are the Hudson's Bay, the Renfrew and Hubbard collections, thus representing adequately the whole game of the Dominion. The centre of this west transept is, correspondingly with the east transept, occupied by a commanding trophy of game and game birds, and even those of the migratory class, arranged with no little tact and judgment. From this point the west gallery is reached. *Here the mineral resources of Canada are set out in full array. So rapid has been the growth of the mining industries of the Dominion during the past decade, that the 549 specimens exhibited at Philadelphia have increased to 725 at South Kensington, contributions coming in large numbers and great variety from the mines of Nova Scotia, New Brunswick, Quebec, Ontario, the North-West and British Columbia, and including many specimens of considerable value shown in the process of various dressings from the simple ore. The practical results likely to follow from this mineral exhibit are considerable. One may, perhaps, be not too sanguine in anticipating that so powerful a witness to Canada's vast and rich mineral deposits will even do much to overcome the prejudice of English capitalists against embarking in enterprise in this direction—a prejudice not altogether unnatural, when one remembers the hands into which some Canadian mining ventures have fallen in recent years. Intimate knowledge, such as the present exhibit will encourage, must, however, bring about a different state of things.* In the west gallery the shafting provided will be used for the display of machinery in motion—always an interesting feature to visitors. Here the skilfully-designed agricultural and general products of the Birmingham of Eastern Canada will undoubtedly be the object of much curiosity to English mechanics, agriculturalists and manufacturers. Beyond the west gallery is the west arcade, in which Canada has been provided with some 2,000 feet for the display of the products of her fisheries. The exhibit made in London three years ago is here brought into requisition, with, of course, large additions of stuffed and preserved specimens of fishes and marine invertebrata, as well as schooners, models of salmon hatcheries, fishing tackle and all utensils for sea and lake fishing. The National Fish Culture Association is taking charge of the oval until a fitting receptacle is ready for it. An interesting feature of this part of the Canadian display will be the intended shipment of fish periodically, from Canadian waters, under the refrigerator process, not for sale, but to demonstrate the practicability of direct shipments of the fish of Ontario, Manitoba and British Columbia by direct Canadian rail to the Atlantic port, and thence to England.—*Canadian Gazette, London, Eng.*

The Drum Lumon mine of Montana distinguished itself during January by the largest production on record. Sixty stamps working thirty days crushed 3,456 tons, yielding \$100,831.19.

Notes on the Progress of Mining and Metallurgy in Europe.

By E. J. BALL, PH. D.

Assistant in Metallurgy at the Normal School of Science and Royal School of Mines, London.)

Written specially for the Canadian Mining Review.

The action of coal-dust in colliery explosions continues to excite considerable discussion, notwithstanding the attention it has already received, and R. Schneider, in remarking on the results of some experiments made at the Segen-Gottes Colliery, Moravia, which showed in direct opposition to those obtained in Dr. Hilt's experiments with dust from the same colliery in the Neunkirchen level—that free-lying dynamite would always explode—the Segen-Gottes dust—states that Dr. Hilt suggested that this was probably due to the detonators that were used being too weak, and to their consequently not exploding the dynamite properly, and that it would be therefore well to repeat the experiments with the triple force detonators manufactured by A. Barnhardt, of Brunswick. This was done, but the results were the same as before, the dust being exploded every time without any gas being present. Schneider is consequently of opinion that the difference in the results of the experiments made at the colliery and at Neunkirchen were due to the excessively fiery nature of the dust, which, he considers, must either have been damp or not sufficiently powdered when used in the trials at Neunkirchen. The general conclusions derived from his experiments have, however, tended to confirm those obtained by Dr. Hilt, and attention is drawn to the fact that in all cases where dry and dusty fiery pits are worked the present method of shot firing cannot possibly be practised without danger.

In referring to the investigation recently made at the Gabriel Colliery in the Karwin district, Austria, on the influence of the changes in barometric pressure on the escape of fire-damp, the results of which confirmed those obtained in previous experiments, showing that the danger increased with a falling barometer, J. Mayer remarks that although this may be true in some respects, the chief danger lies in accumulations of coal-dust.

J. Haller has described the method of treatment adopted in working the brown-coal deposit at Liescha, Austria, which is 25 feet thick, and he states that the one originally employed—stopping—caused the ventilation to be so bad, and the temperature so high, that it was abandoned, and a modified post and stall work introduced in its stead. The result was that not only was the ventilation greatly improved, but the work done per man and per shift increased by 39 per cent. The drawing engines in the pit were, until two years ago, worked by steam brought down to them in pipes; this has now been replaced by compressed air with very satisfactory results. The wooden timberings, which had to withstand considerable pressure, and, in consequence, to be frequently renewed at certain places, has been replaced by steel rails, and although their first cost is greatly in excess of that of the wood, they have proved in the long run much more economical.

With regard to the sinking of shafts, J. H. Poetsch has taken out additional patents in Germany, and elsewhere, in which he proposes to employ the pipes he has used in freezing the quicksand through which it was desired to sink the shaft, after it has been sunk and the ground thawed again, either in connection with pumps to partially remove the water or as supports by

filling them with cement, or by otherwise strengthening them.

H. Thomas, of the French Geological Survey, discusses in the *Génie Civil*, the size of the pillars which should be left to support the roof in underground workings, and he gives some figures relating to building stone, calculated from the resistance offered by the materials to crushing stress.

The mineral wealth of Spain is exceedingly great, and its natural advantages are such, that should the country ever succeed in obtaining a settled form of government, its mineral resources are sure to receive considerable attention, and this tends to endow the description by R. A. de Yarza of the mineral deposits of the Province of Guipúzcoa (*Revista Minera of Metalúrgica*, 1886, Jan. 17 and Jan. 24) with considerable interest. The ores found are chiefly those of lead, zinc and iron, as although copper ore has been found it has only been in small quantities, and up to the present is of no importance. No coal beds have been discovered, but some lignite deposits exist in the cretaceous rocks. The galena occurs principally in lodes in palæozoic measures, those occurring in the cretaceous being of far less importance. Zinc blende is also found both in the palæozoic and cretaceous rocks, and calamine also occurs in considerable quantities. Iron ore deposits are abundant, and would be of great importance were they not so close to those of Biscaya, with which it will be difficult for them to compete successfully. The ores, which are of good quality, occur partly as contact deposits between granite and palæozoic rocks, partly in the palæozoic rocks themselves, and occasionally also in the cretaceous.

H. Tweddle describes in *Engineering* the petroleum regions of Europe and Asia, and he states that they extend from the north-western extremity of Great Britain diagonally across Europe, the Crimea, and the Caucasus, and that they terminate in Central Asia. This zone embraces nearly all England and Scotland south of the Grampians, Hanover, Bohemia, Galicia, Moldavia, Roumania, Transylvania and Hungary, the Crimea, the Caucasus chain, and in the trans-Caspian regions, the Island of Tchelen, Krasnovodsk, the Neft Gora, the Heri Rud, and Tashkent, the last explored petroleum region in Central Asia. He remarks on the great similarity of the geological measures where petroleum is known principally to exist, viz., in the cretaceous, though it is found in every formation from the granite and volcanic rocks to the highest and most recent deposits of the Aral-Caspian, and he considers that the zone may fairly be regarded as more or less similar to the petroleum fields of North America. These, it may be mentioned, have been recently described at considerable length by C. Zincken, of Leipzig, Germany.

Turning from mining to the kindred subject metallurgy, the iron and steel industry first claims attention. The chief object of discussion at present is as to the relative advantages of large and small Bessemer converters, and it would seem to be the general opinion, that however advantageous small converters may be under certain conditions, yet, that under ordinary circumstances, it will be impossible for them to compete successfully with large ones.

The basic process is making rapid progress on the continent of Europe, but the progress is somewhat slower in Great Britain, where the abundance of pure ore renders it unnecessary to work deposits of ore which are of lesser purity. Magnesite is coming into considerable use in the manufacture of basic bricks.

Arrangements for the collection of the waste products from coke ovens are gradually being

made use of in the case of those already constructed, and a considerable number of the more modern forms of ovens have been lately erected, the tendency being to employ almost solely horizontal ovens of the modified Coppée type. Compressing the coal by means of rollers after charging, has, it is stated, enabled, in the case of certain German coal, a much better coke to be produced than would otherwise have resulted. It appears to be generally considered that the collection of the ammonia from the waste gases of blast furnaces using coke as fuel is not likely to prove very profitable.

The Manhès process for the Bessemerizing of copper regulus is assuming considerable importance, and the latest form of converter proposed by Manhès, and exhibited by him at the Antwerp Exhibition, resembles in shape the boiler of a horizontal engine. It is cylindrical, and rests on a truck. The tuyère box runs along the side, and holes in its back facing each tuyère permit of rods being inserted through them to keep the nozzles free. The converter is revolved by means of a tooth-wheel and gearing, and the throat is in the centre of the upper portion.

Electrolytic processes are also making considerable advance, though their progress has not been so rapid as was at one time anticipated, the chief reason being that the comparative abundance of fuel and of skilled labor renders it impossible for processes which rely chiefly on the saving effected in these respects at the expense of time to compete with others which enable the capital invested to be turned over far more rapidly. In the case of copper, too, although electrolysis enables the gold and silver present in the material treated to be collected, and a metal to be produced which commands a higher price in the market, still the great majority of the ores contain such small percentages of the precious metals that they, and the higher value of the copper produced, would not compensate for the loss of interest on the capital invested. In countries, however, where fuel is either scarce or costly, and labor expensive and unskilled, electrolytic processes certainly deserve a far greater consideration than they usually receive, more especially in such places where water-power can be made use of, or where the materials to be treated contain an appreciable amount of the precious metals. Electrolytic plants for the treatment of cupriferous materials are, however, being built in various parts of Europe. There are several in the United Kingdom, and they chiefly use metallic anodes, concentrating the silver and gold in "bottoms," which are afterwards cast into the desired shape; anodes of regulus have also been tried, but, I believe, without marked success, although works have recently been erected at Stolberg, in Austria, and in the neighborhood of Genoa, where regulus alone is intended to be used.

Scarcely any attention has been paid in Europe to the employment of electrolysis in the case of lead, but attention is beginning to be directed to its use in the case of zinc ores, though I am unacquainted with any works employing as yet such a process on a commercial scale.

Very many different types of dynamos are in use at works, and in choosing one it seems customary to select that which converts the greatest percentage of energy into electricity; but, however correct this may be from the point of view of an electrician, from that of a metallurgist this perfection of the machine should be by no means the sole consideration, as simplicity of construction and the ease with which repairs can be carried out should receive careful consideration, more especially in such cases where the position of the works will render it impossible

to obtain skilled assistance in case of a breakdown, and where the machine will have to be entrusted to persons who, it may be, have had no experience in its management, and who are wanting theoretical knowledge. Of course no machine should be chosen unless it gave fair results, but I lay stress on the advisability of it being as simple as possible in construction, as this is very frequently overlooked, and my attention was drawn to the subject in the Works where I studied the process.

Two or three adoptions of electricity to the treatment of gold ores have been more or less discussed of late, but opinion is still very much divided as to their merits.

Numerous so-called improved forms of amalgamators, &c., have been proposed, but most appear worthless, and the great majority of the others have scarcely advanced beyond the patent stage.

CORRESPONDENCE.

MINING RECORDS.

Editor Canadian Mining Review.

Experience in the old world may be of use in the new. In Ireland, the earliest written record I can find is one A. M. 3656, and since then they are few and far between. There are, however, other records, in the old attics and other waste heaps; but who were the miners? and when were they worked? or what they did underground it is impossible to say. The latter is even the case with works carried on within the present century, not a record having been kept except in a few cases, and if an adventurer starts a mine in or near an old sett, he has to take chances, while after he has come on a good lode and made all preparations for working a mine, he may find that the "old men" have been before him and cut out all "the riches." This has been the case over and over again in our modern mining operations; "old men's workings" have spoiled many a good mine. Yet what can be done? Out of the thousands of mines that, from time to time, have been in operation in Ireland, I believe there are not the records of fifty, if of half that number.

I read with great interest the evidence given before the Enquiry held some times since in Ottawa, and had a fellow feeling with the geologists examined, as no matter how zealous, anxious or painstaking a geologist may be, unless he has the power to say—stand and deliver! he cannot get records from unwilling hands.

At the present time, according to the new act, mining agents must annually return records of their working—but not of old workings which are those of most importance in connection with further research. During the last 30 years or more, I have been endeavouring to get copies of these old plans and sections, and in no important mine have I perfectly succeeded. In some few small workings I was able to do so, but invariably in the large ones I was unsuccessful. In most cases the mines had gone through different hands, and at each successive sale of the property, the sellers had either kept back or destroyed all records, except those that they considered advantageous to themselves; consequently to get full plans and sections would necessitate expensive surveys that the company or I could not undertake—or the agent or company might be unwilling to allow the extent of the works to be made public—they might let you look at the plans and sections and say you might copy them, but invariably I found it hard to accomplish the latter,

and never without an amount of tact. When an agent pretends to be willing and at the same time intends to prevent you getting copies of his plans, it takes a great deal of stratagem to circumvent him.

These are my experiences. Some agents cannot give statistics unless he went to great expense in new surveys, while others will not, as they are afraid it might possibly be hereafter detrimental to their interest. To get statistics, therefore, it is necessary to make it compulsory that plans and sections of all mining operations should be furnished to an authorized official, as otherwise no one, no matter how energetic or painstaking, can procure them. The great losses due to unrecorded mines in the "old countries," British and foreign, ought to be a lesson to the new, and teach them to "take time by the forelock." Let them have properly appointed officers whose duty it is to record all mining operations, and to whom all statistics of such operations must be given. In a new country this could be easily managed by insisting on all mining adventures being registered. The register fee might or rather ought to be merely nominal, but coupled with it should be an obligation to furnish, at specified times, full accounts of all mining operations, the neglect of complying with the latter subjecting them to severe penalties. Such a law would not prevent individual research, while it would protect subsequent adventures and the losses so often due to bogus companies.

J. HENRY KINAHAN.

NOVA SCOTIA GOLD FIELDS.

PAY-STREAKS.

Editor Canadian Mining Review.

Not having had the advantages of a personal knowledge of the "Pay-Streaks," I was led, from the descriptions that I had seen, to suppose they were the filling in of vertical shrinkage fissures. Mr. Gilpin's very instructive description of them in March number of the REVIEW, however, seems to suggest that they are the shrinkage fissures on the arch of an anticlinal curve, dipping or "hading" more or less at a high angle at the line of axis of that curve; and these in each district in accordance with the strike of the line of axis, occur in local systems having similar strikes and underlie, the strikes being parallel to the line of axis. If this is the case the fissure ought invariably to decrease in width gradually in depth; the decrease in width being more gradual the more perpendicular the streak—that is, the less the angle between the dip of the streak and the vertical of the axis of the curve, the less the variations in the width of the fissure—that is, the fissures at or near the crown of the arch of the curve, ought to be more uniform in width as followed down than if away from the line of the crown of the arch; the farther from the crown the greater the opening at the surface. This can be seen in sharply folded strata, the quartz veins filling such shrinkage fissures when nearly perpendicular thinning very gradually, while, if underlying at lower angles, the change in their width is much more rapid. If "Pay-Streaks," are the filling in of fissures of this class they must die out in depth and finally end. There is, however, the converse to this: What are the shrinkage fissures in the sides of a synclinal curve? Ought they to open in depth? Is the tension in the strata forming the anticlinal curve similar to the tension in the strata forming the synclinal curve? Of the latter, however,

I cannot speak, as my experience has never furnished an example.

NORTH SHORE MINES.

LAKE SUPERIOR DISTRICT.

Editor Canadian Mining Review,

SIR,—Seeing in your valuable paper for frequent accounts of the tests at the silver mines in this district, also at the Huronian Mine in the gold region, during the past year, I think a word would not be out of place respecting some of the silver mines upon this shore which were worked more or less twelve years ago.

I speak as a miner who worked in most of the mines mentioned below, and can vouch for the facts in each case.

I will first take the "Silver Harbour" mine. The main shaft at this mine was sunk 120 feet, and another some 30 feet. There was a large amount of black sulphide of silver and silver ore taken out, sufficient, if the mine had been properly handled, to pay working expenses; and when the work was stopped the mine looked well, so much so that an American gentleman would have worked it right along if he could have procured the property on reasonable terms and without restrictions. The company who worked this mine literally squandered their money by erecting a splendid building, which cost some fabulous sum, and was wholly unnecessary; they also spent a large amount for engines and machinery for stamp-mill, which were never used and subsequently went to ruin, instead of opening up and testing their mine at the outset—which has never been done. It is my belief that had the company been mining men, or their manager a practical mining man, this mine would be working and paying large dividends at the present day.

I will next take the "3 A" mine, which is upon the adjoining location to "Silver Harbour," but a distinct vein. The main shaft is down 140 feet, and another about 40 feet. There was a large amount of native silver and nickel silver taken out at this mine; certainly some of the largest specimens of native silver ever taken out on the North Shore were from "3 A," and there was a very fair show of silver when work was suspended. "3 A" may be classed with "Silver Harbour" as regards mismanagement, for there was sufficient silver taken out to pay all expenses and leave a handsome balance had it been properly taken care of.

Should the owners of either "Silver Harbour" or "3 A" mines place their properties upon the market as assessable stock, I am assured the people in this district would readily take them up.

At "Thunder Bay" mine there was only one shaft sunk, about 100 feet in depth, from which a large amount of native silver was taken out, sufficient to pay working expenses if the mine had been worked economically; but here again the company incurred the expense of valuable machinery and stamp-mill, which were afterwards left to ruin, before proving their mine in any way. It is my opinion that should a strong company take hold of this mine and have it thoroughly tested it would turn out well.

"Jarvis Island" was worked and tested to a depth of 130 feet, and found to carry some native silver and silver ore, and when abandoned there was a good show of silver. The

owner of this property intends, I believe, to start work again this spring.

"Spar Island" has not been worked for some 40 years, though it is said to be one of the best mines on this shore. The main vein carries grey copper ore and native silver, a large amount of each, and is 12 feet wide; there is also another vein four feet wide. Some few years ago a gentleman in Port Arthur, who has the control of this estate, had some very fine specimens taken out. The vein shows equally good upon the mainland.

The only mine which has in any sense been tested in this district is "The Duncan." The main shaft was sunk 900 feet, and another shaft 150 feet; the longest drift is 400 feet. The company was a good one, the best upon this shore to the present day, and for 700 feet along vein from main shaft the mine was very fairly tested. They obtained a large quantity of native silver for about 400 feet upon surface, and considerable at a depth of 100 feet, and the core from diamond drill usually assayed silver wherever tested upon vein. The testing upon this 700 feet of the main vein was considerable, but the company did no work or exploring except upon this one vein, although there are several others upon the location all carrying good mineral. It has been reported that a large deposit of silver has recently been discovered upon the location by one of the men who previously worked at this mine.

All the above mines are easy of access, either water, road or rail facilities being excellent, and there are numerous other locations around this district which could be profitably worked under efficient and economical management.

There is no doubt that the owners of the properties in the new silver district and gold region have taken warning from the previous experiences of mining upon this shore and have gone to no unnecessary expense until assured of an adequate supply of mineral to pay for expensive buildings and machinery; but as I see in your paper that capital is seeking investment in mines and mineral lands, I am sure it would amply repay the capitalist to visit and take note of the mines above mentioned, in addition to the new mines which are being opened up all around us.

Yours truly,

"A MINER."

Port Arthur,
Lake Superior.

FOSSIL HUMAN FOOTPRINTS.—Herr H. E. Low has obtained and forwarded to the Imperial Museum in Vienna twelve large stone slabs bearing the foot-prints discovered last year in the solid rock in the quarry over Lake Managua, in the territory of Nicaragua. The interest was increased by the statement that those foot-prints had been overlain by eleven different layers of stone, extending to a depth of four meters, and indicating an antiquity for our race quite transcending all conjectures hitherto hazarded. They are about three quarters of a meter square. They can now be inspected by European geologists. The foot-prints are sunk into the stone to a depth of from eight to ten centimeters. The stone itself is a porous tufa, and the superincumbent layers, which had been removed for building purposes, were all of a more or less solid volcanic conglomerate. The foot-prints are very conspicuous, and seem to be those of three distinct persons, one of whom was a child.

The proprietor of Montvale Springs in Blount County, Tenn., has sunk a shaft ninety feet deep on his property and claims to have found a rich vein of silver ore.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

Mineralogy of Pliny.

To a student who is following a course of science and literature, many questions of strange interest present themselves. In his scientific studies, on the one hand he becomes aware of the latest discoveries of the day; he is perfectly acquainted with the physical structure of the globe, and seems as conversant with what is written in the records of nature, as the book-worm is with the productions of his favorite author. On the other hand, his literary pursuits transport him into the far past, into the ages of antiquity, and bring before him the simplicity of men of by-gone days, with their odd superstitions and quaint beliefs. He cannot fail to remark the striking contrast between the opinions of the most intelligent and learned of the ancients, and those of the mere student of science of our day.

To exemplify this general idea, we may consider a particular case. See what difference there exists between the knowledge which we have to-day of mineralogy and that which the ancients possessed. A mineralogist who has been so happy as to fall in with Pliny's treatise of mineralogy cannot fail to be amused. During the days when Pliny flourished, a scientist was far different from what he is at present. Whatever was known at Pliny's time, Pliny knew; and whatever Pliny knew is to be found in his admirable works. By reading this author, therefore, we can have an adequate knowledge of what the ancients knew, and in Pliny we can study the light in which mineralogy was once regarded.

Five lengthy books of his "Natural History" are devoted to minerals. But, gentle reader, were you to peruse a work on moral philosophy or a volume of rhetoric, you would then know nearly as much mineralogy as you would after the perusal of Pliny's dissertations.

What, indeed, are these five books if not mere rhetorical dissertations, replete with moral reflections? Admirably written, indeed, his works cannot fail to interest. He has paid great attention to his style and choice of words. He discourses on the ill effects of gold and silver and of the precious stones, and does not hesitate to denounce them as the bane of Roman society. He is loud in his lamentations because of the introduction of these "articles of luxury," the cause of effeminacy, the corrupter of morals. This is his unceasing strain while he is speaking of gold, and occasionally he is strong in his invectives against the unknown inventor of such and such a perfidy.

In the first of his five books he treats of metals, beginning with gold. After a severe criticism of Roman luxury, we are presented with a complete history of rings, then of crowns, and lastly of gold coin, the invention of which "was an enormous crime against humanity." A slight allusion to the ductibility of gold and the manner of procuring this metal is what comes nearest to the subject of mineralogy. Read what he says about silver, and you have a good idea of ancient mirrors, vases, plates and statues of silver. Read his second book, on copper, and you have a perfect knowledge of bronze statues and chandeliers. We must not

omit medicine; this is a strong point in Pliny's works. He delights in dwelling on the medicinal properties of the metals, most of which were used for that purpose in his time. In fact, iron and lead are scarcely treated under any other head.

The third book is an excellent treatise on painting; the fourth is devoted to marble sculpture, while the fifth treats of precious stones. This is by far the most useful part of Pliny's work. He displays in it a wonderfully extensive knowledge of the gems which had become at that time very extensively used in Roman society. It is needless to state that, in a strictly mineralogical sense, his vast erudition fails to give even a clue to the science of gems. His classification is entirely artificial. Gems which, for instance, are varieties of quartz are given as totally different species; whilst others, widely different in composition and crystallographic characters, are brought together with regard solely to their external properties. But we are inclined to be indulgent towards the old Roman *savant* when we consider the amount of invaluable information he imparts and the graceful diction he employs, and we willingly admit that science would soon become popular if all scientists could and would imitate Pliny's attractive style.

W. A. H.

Aluminum.

"The metal of the future" is the designation given to aluminum by the President of the Scranton Board of Trade, in an address before that body. Possessing all the good qualities of iron without its weakness, it will, he thinks, in time totally replace that, at present, most useful of metals. Aluminum is now principally used in alloys. But its resistance to oxidation eminently fits it for household utensils, its lightness compared with its bulk makes it very suitable for architectural purposes, and its use in building steamships, and furnishing railways with their rolling stock, would revolutionize present rates of travel. It is a much better conductor than iron, and would replace that metal in telegraph wires; knives, swords and axes made of alloys of aluminum receive a much better temper than the finest steel. The great objection to the use of this metal, which is so abundantly diffused, has hitherto been the cost of reducing it from its ores. But President Price asserts that the price of aluminum is now only \$15 a pound, which is 50% less than it was thirty years ago; and a company in Cleveland claims that within the past year, by a new process, they have made it possible to reduce the price to \$4 a pound. If aluminum really possesses all these qualities in such a high degree, we may indeed prepare to witness new achievements, which will throw those already accomplished into the shade.

D. PHALEN.

Germanium.

Prof. Clemens Winkler, writing in a recent number of *Nature*, announces the discovery of a new element by himself. In the summer of 1885 a new mineral was discovered at Himmelsfürst, near Freiberg, in Saxony. This mineral was a rich silver ore, and received the name of *argyrodite*. Before the blow-pipe it yielded sulphur, silver, and a little mercury, in the following percentage: mercury 0.21 per cent., silver 73 to 75 per cent., sulphur 17 to 18 per cent. A small quantity of iron and traces of arsenic were also present. But there was always 6 or 7 per cent. un-

accounted for. Prof. Winkler claims to have discovered that this portion of the mineral contains a new element, which, in honor of his country, he has named *Germanium*. Germanium resembles antimony in its properties. The presence of arsenic and antimony in the minerals accompanying argyrodite made the discovery of the new element very difficult. On heating argyrodite in a current of hydrogen a black, crystalline and moderately volatile sublimate is formed, consisting of the sulphides of germanium and mercury. Germanium sulphide dissolves in ammonium sulphide and is precipitated in a pure state by hydrochloric acid. On heating germanium sulphide in a current of air, or warming it with nitric acid, a white oxide, non-volatile at a red heat, is produced. This oxide is readily reduced by hydrogen, but the reduction of the sulphide is more difficult on account of its volatility. Germanium, like arsenic, has a grey colour, and a moderate lustre. It is volatile only at a full red heat, but much less so than antimony. Its crystals could not be mistaken for those of the latter metal. The atomic weight of germanium, when ascertained, will show whether this element is to occupy the vacant place in the periodic system between antimony and bismuth.

COAL GAS.—It has been lately discovered that the heat value of coal gas has been rated too high, up to the present. A French chemist has ascertained that the real heat value is 15 per cent. below what it was thought to be, or 5,200 instead of 6,000 calories per cubic meter at 0°.

TIN.—Some of the supposed causes of the disintegration of tin are discussed in the *Mining and Scientific Press*. The idea of a dimorphesin is suggested by the fact that the disaggregated tin is of a lesser specific gravity than was the tin in its former state. The presence of mercury in the metal is another possible cause of its disintegration.

GEMS.—The *Jewelers' Journal* gives the following chemical directions for making artificial gems. To make the *sapphire*, heat 4 oz. of aluminum oxide and 4 oz. of red lead to a red heat. When smelted add 10 grs. bichromate of potassium and 17 grs. cobalt oxide. Stir up well and keep cool. The *ruby* is produced by the following process: Heat 4 oz. of aluminum oxide and 4 oz. of red lead to the smelting point, and add from 7 to 16 grs. of potassium bichromate. For the *emerald*, to the same quantity of oxide of aluminum and red lead, add from 8 to 12 grains of sodium uranite, and treat as above. Parisian or Alaska *diamonds* are made by heating 65 per cent. of pulverized crystal quartz, 20 per cent. of red lead, 8 per cent. of pure carbonate of potash, 5 per cent. of boric acid, and 2 per cent. of white arsenic. The brilliancy of the diamonds depends upon the purity of the red lead and of the carbonate of potash.

COPPER AND NITROGEN.—M. Blendlot, of the French Academy of Sciences, has observed a curious phenomenon with respect to the action of nitrogen on copper. A disk of platinum and a disk of copper, 0.03 meter in diameter, were placed 3 or 4 millimeters apart, under a bell jar of porcelain open below, and were fixed vertically in front of each other by means of platinum stands. The whole apparatus was then heated for three hours by a gas furnace.

At the end of that time, although there had been no electric current, the face of the platinum disk was found blackened with a deposit containing copper and platinum. In short, the copper had crossed over to the platinum. By repeating the experiment in a different gas, M. Blendlot ascertained that the nitrogen of the air had been the agent of the transfer by combining with the copper, which it afterwards deposited on the platinum.

MELDOMETER.—Prof. Joly, of Trinity College, Dublin, has described, in *Nature*, an apparatus contrived by himself, by which he can determine or compose the melting points of minerals, and their behaviour at high temperatures, either alone or in the presence of reagents. To this apparatus, which is to be attached to a mineralogical microscope, he gives the name of meldometer. He says, "As I now use it, it consists of a narrow ribbon of platinum (2 mm. wide), arranged to traverse the field of the microscope. The ribbon, clamped in two brass clamps so as to be readily removable, passes bridgewise over a little scooped-out hollow in a disk of ebony (4 cm. diam). The clamps also take wires from a battery (3 grooves cells), and are adjustable; the resistance being placed in circuit, the strip can be raised in temperature to the melting point of platinum." The platinum strip is placed in the field of a 1" objective, and a wedge of tainted glass is used in photometrically estimating the temperatures, by extinguishing the field. Approximate estimations of the temperature are made in terms of the resistance of the platinum strip. These observations may be compared with the readings on the wedge, which are then used for ready determinations. The mineral is placed in small fragments near the centre of the platinum strip, and the current increased till the melting point is apparent. By means of this apparatus, Prof. Joly has melted beryl, orthoclase, and quartz, and discovered for the first time that the last fuses below the melting point of platinum.

BEAUTIFUL MARBLES IN ALGIERS.—The rediscovery of the ancient quarries where the beautiful antique marbles were obtained is interesting. An extensive quarry, covering two thousand acres, has been quite recently discovered in the province of Oran, near the Mediterranean coast, in Algiers. The deposit has been obtained by an Italian who has constructed roads and begun operations. The deposit contains giallo antico, breccia, and cipoline, besides black and white marble. These fine colored stones can be laid on the wharf at Oran for about one dollar a cubic foot. The beautiful yellow marble, giallo antico, has, until this late rediscovery, been unknown, save by the fragments found in Roman ruins two or three years ago.

AN IMPORTANT EXPERIMENT.—The mining public will be much interested in the results obtained from the experiments which are to be made by means of a dynamo to be set up on the Truckee river in Nevada to transmit thence the whole motive power of that stream—furnished by a Laffel turbine, with a full head of water, with 100 feet fall—to a receiving dynamo at Virginia City. Those engaged in this operation claim that in this way a motive power can be furnished at Virginia City for a hundred-stamp mill for \$200. At present, the daily cost of transporting Comstock ores from the mines to the mills on Carson river is \$1,000, nearly all of which will be saved by having the mills directly at the mines.

NOVA SCOTIA.

Considerable attention is now being directed to Lunenburg county as a promising gold field.

The Empress mine in Renfrew district produced 284 ounces of gold during the month of March.

Miners have been working on tribute at the Mount Uniacke mines and have been earning about \$75 per month per man.

It is stated that a rich streak has been struck in the Rawdon mines, and that one thousand ounces of gold were taken from it during the first two weeks of March.

The first clean up at the Crow's Nest mine, in the Sherbrooke district, Gaysborough county, showed a yield of 75 ounces of fine gold from 37 tons of quartz put through the mill.

At the Antimony Mines at West Gore, Hants County, two inclined shafts and one perpendicular have been sunk. The ore is at present hoisted by horse power, but it is the intention of the owners to put in steam hoisting gear. Forty men are now employed in the mine, and their number will be increased to 60 or 70. 100 tons of ore, valued at from \$50 to \$55 a ton, are shipped monthly to England via Halifax.

Those interested in the development of the gold mines of this province are anxious that the local government should incur the expense of sinking a shaft to the depth of 1000 or 1200 feet for the purpose of proving the continuity or recurrence of the "pay-streaks" in quartz veins. As no practical test has yet been made, and as there is good reason to believe that deep mining would pay, it is not unreasonable to ask for government aid in settling the question. The government receives a royalty on all the gold mined in the province, and would, therefore, be warranted in incurring the expense of so practical a test, in view of the possibilities which might result therefrom.

ONTARIO.

(Thunder Bay District)

It has been reported that the miners at *Rabbit Mountain* have come upon a very rich vein, but the report has not been verified.

At the *Huronian* mine the shaft is now down 200 feet and at this level the vein is six feet wide, and producing ore that mills \$20 a ton.

A mica deposit, situated about fifty miles west of Port Arthur, will probably be developed this Spring and its actual value ascertained.

At the East end of Silver Mountain a branch vein is being followed alongside the main one. It carries rich ore and is eighteen inches wide.

Steam drills, air compressors and miscellaneous machinery, arrived at the *Beaver* mine in March, and are probably in working order by this time.

Some fine ore is now in sight at *Silver Falls* mine but the work of development is not being driven as actively as the location deserves.

The main vein has been reached at East End Silver Mountain mine. It shows very rich and work is being vigorously pushed ahead.

Work is progressing favourably at *Crown Point* mine and the promising character of the ore warrants continued efforts being made towards further development.

The site on which the mill for the *Beaver* mine is to be erected is on Silver creek, in a position convenient to the *Beaver* and *Silver Creek* mines, and a tramway has already been located thereto.

Mr. Richard Crow has been engaged to operate the mill at the *Beaver* mine. This gentleman was employed last year by the Huronian Gold Mining Company, and proved himself a competent mill man.

Preparations have been in progress to open up four mining locations in Black Bay country along the line of the Canadian Pacific railway, between Loon Lake and Black Sturgeon river. These include three argentiferous galena veins.

BRITISH COLUMBIA.

About six miles of McCulloch creek is available for mining and it is thought several hundred miners will make good pay there during the coming season.

A large amount of eastern capital is finding its way into Big Bend country, and it is expected that the placer and quartz claims will be vigorously worked.

The Homestake company, who are working on the Tulameen fifteen miles above Granite creek, took out \$523 in gold for three days work the last week in March.

Until the water lowers in the creeks of the Semilkameen district it will be impossible to resume mining operations, and this is not looked for until the end of May, or later.

Mining on Granite Creek received a check in the beginning of April. Work had been in progress for some weeks when a warm spell caused a freshet, necessitating the suspension of mining for an indefinite time.

Camp creek, Cairn creek, French creek, Gold creek and McCulloch creek, in the Big Bend district, will be worked to some extent this season, and it is expected a lively camp will spring up near the mouth of McCulloch creek.

It was expected that bed-rock would be reached about May 1st on the Barrett claim which is located on McCulloch Creek, higher up than the Ophir Bed-Rock Flume Company's. The tunnel is in 600 feet.

Mr. D. Jordan, of San Francisco, who recently purchased a tract of coal lands contiguous to the Wellington mines, has been superintending the sinking of prospecting bores and the extension of the slope. He is well satisfied with the result of these operations up to the present time.

In accounting for the failures in quartz mining in the Cariboo district heretofore, it is said to be due to improper treatment of the pyritous quartz which is said to carry \$20 to the ton in

finely disseminated gold locked up in the sulphuret and which has been worked as free milling ore. Thus, for the want of concentrating machinery, the pyrites passed off, carrying the gold with it.

At a public meeting in Farwell in February it was decided to petition the Local Government to aid in improving the means of communication between the Big Bend mines and Farwell, including the construction of a waggon road from La Porte to Ground Hog Basin, at the head of McCulloch's Creek, so as to facilitate the transportation of machinery and supplies to the various mining camps.

The Ophir Bed-Rock Flume Company propose constructing a flume the entire length of their ground which extends for a mile and a half along McCulloch Creek, in the Big Bend district. Into this will be hydraulized the gravel for 100 feet in width down to bed-rock, 60 feet below the surface. The flume will be seven feet wide, through which it is intended that 1000 yards of earth will pass each twenty-four hours. The gravel prospects ten cents to the pan.

UNITED STATES.

Colorado is credited with a bullion product for 1885 of \$22,800,000, of which \$13,000,000 was silver, \$5,000,000 gold, \$4,000,000 lead, and \$500,000 copper.

The Ropes gold mine, Michigan, for the month of February, produced from bullion and concentrates, about \$3,000 in precious metal, averaging about \$6.50 per ton of rock treated.

The shipments of last season from the Quincy mine, Mich., to Detroit smelters, aggregated 7,091,765 pounds of mineral which yielded about 82.47 per cent., or 5,848,197 pounds, of refined copper, and gave a mining profit of \$229,895.45.

**MINING REGULATIONS**

To Govern the Disposal of

Mineral Lands other than Coal Lands.**1886.**

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed twenty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labour during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, beach, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES, AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, &c., &c.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1ST OF JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with, or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein, or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section, or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

NOTICE.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Indian Supplies" will be received at this office up to noon of TUESDAY, 20th APRIL, 1886, for the delivery of Indian Supplies during the fiscal year ending 30th June, 1887, consisting of Flour, Bacon, Beef, Groceries, Ammunition, Twine, Oxen, Cows, Bulls, Agricultural Implements, Tools, etc., duty paid at various points in Manitoba and the North-west Territories.

Forms of Tender, giving full particulars relative to the Supplies required, dates of delivery, &c., may be had by applying to the undersigned, or to the Indian Commissioner at Regina, or to the Indian Office, Winnipeg.

Parties may tender for each description of goods (or for any portion of each description of goods) separately or for all the goods called for in the Schedules.

Each tender must be accompanied by an accepted Cheque in favour of the Superintendent General of Indian Affairs on a Canadian Bank for at least five per cent. of the amount of the tenders for Manitoba and the North-west Territories, which will be forfeited if the party tendering declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted the cheque will be returned.

Tenders must be made up in the Money column in the Schedule the total money value of the goods they offer to supply, or their tender will not be entertained.

Each tender must, in addition to the signature of the tenderer, be signed by two sureties acceptable to the Department, for the proper performance of the contract.

In all cases where transportation may be only partial by rail, contractors must make proper arrangements for supplies to be forwarded at once from railway stations to their destination in the Government Warehouse at the point of delivery.

The lowest or any tender not necessarily accepted.

L. VANKOUGHNET,

Deputy of the Superintendent-General
of Indian Affairs.

Dept. of Indian Affairs,

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

It is not to be expected that the work of collecting and compiling information and statistics in connection with Canadian mines and minerals can be done in a manner that will be acceptable to the mining public until such time as a distinct branch has been added to the Geological Survey for this purpose.

Messrs. Coste and Ingall, the two Mining Geologists of the Survey, have been entrusted with this important work, and what these gentlemen will do in the direction of organizing and conducting a mining and mineralogical department will no doubt be well done; but their united efforts will be inadequate to supply the mining community with the desired information within the next decade of years, if ever, unless efficient assistants are appointed under them and they themselves are allowed to devote their whole attention to the work. At the present moment these gentlemen are pursuing their geological research in the field and will continue to do so during the summer months, after which they must prepare their reports and maps. Meanwhile no progress is being made with mining statistics. If there is to be such a thing as a mining and mineralogical department attached to the Survey, it must be established on a permanent basis with an adequate and efficient staff under one officer. Then, and not until then, may we look for such organization as will produce the end aimed at, and furnish us with the information so urgently needed by the mining public and of such vital importance to the country at large.

Professor Chapman, of Toronto, visited Ottawa recently on his return from the Beauce gold district where he had spent several days examining the property now being worked by the St. Onge Gold Mining Company. He expressed himself highly pleased with what he had seen and greatly astonished at the richness of the ground, and is firmly of the belief that gold mining will pay largely if properly conducted. He witnessed the washing of gravel from one of the drifts from the main shaft, from which a quantity of coarse gold was obtained, the nuggets varying in size from that of a pea to a bean.

Dr. Robert Bell, Assistant Director of the Geological Survey, will shortly proceed to Hudson Bay, where he will prosecute further exploration in the interest of mineralogy, geology and science. He will go by the overland route and will be absent for some months. Dr. Bell has already furnished the Geological Survey with a vast amount of information on the mineral resources of that far north country, acquired by personal observation. He has given a great deal of attention to portions of the Hudson Bay mainland, and has suffered hardships in order that his researches might be of practical service to the public.

Mr. A. C. Lawson will leave Ottawa during this month to continue his survey of the Rainy Lake district and will be absent for the rest of the summer. Mr. Lawson's report of that section of country will be published in a complete form in the next Report of Progress of the Geological Survey, and, as his work is always thoroughly and well done, his report will undoubtedly abound in interesting information.

Mr. Eugene Coste, Mining Geologist for the Geological Survey, is at present engaged in the mining district of the County of Hastings and expects, during the summer, to complete his examination of that section, begun last year. Mr. Coste's report will be looked for with much concern as it will no doubt be replete with interesting mining statistics and valuable information bearing on the mineral resources of the Hastings district, where rich gold-bearing veins and extensive iron ore deposits are known to exist.

Mr. E. D. Ingall, the other Mining Geologist of the Geological Survey is now in the Port Arthur district continuing his last year's survey of the Thunder Bay mining region in order that he may be enabled to complete a geological map of that interesting section of country and make an exhaustive report of its mineral resources. Mr. Ingall will have an opportunity of inspecting some of the mining properties in the neighborhood, and we earnestly hope he will collect statistical information of work done and such other information as will enable outsiders to form an intelligent idea of the possible future of the north shore of Lake Superior as a mining section.

The Gold Commissioner of Cariboo, B.C., in his annual report for 1885 to the Minister of Mines, states that in his district another year has passed without any material development of the quartz ledges, and, with the exception of the efforts put forth by the Quesnelle Quartz Mining Company, nothing had been attempted in this direction. The Quesnelle company were, he states, making a most laudable attempt to prove the value of their mine at Hixon Creek, and had purchased an engine and other machinery at San Francisco and engaged the services of experienced Californian quartz miners.

In our next issue we will publish a report of Mr. G. A. Koch, addressed to the Trustees of this company, which is highly satisfactory, and goes to show that at no distant day we may receive the intelligence that a valuable mine has been developed in this out of the way district, which will be an important gold producer. Mr. Koch, the present manager for the Quesnelle Quartz Mining Company, was temporarily engaged last year at the *Huronian* gold mine, Lake Superior district, and the work he accomplished there gave ample evidence of his ability to successfully conduct the development of a mining property.

The *Iron Trade Review*, of Cleveland, Ohio, one of our most valued exchanges, has done us the honour of reprinting an article which appeared in the editorial columns of our last issue on the *Morrison Tariff*, and in so doing prefaced it with the following complimentary notice:

"Our excellent contemporary, the CANADIAN MINING REVIEW, is possessed of a degree of frankness which is to be envied in this day of deceit and dissimulation. It would be pleased to see the United States open its markets to Canadian iron ore and coal, for the very simple and obvious reason that such an arrangement would benefit Canada first, last and all the time, and it isn't afraid to say so. At the same time it doesn't hope much for any substantial aid from the advocates of Free Trade, either in this country or in England."

And we are yet of the opinion that the Dominion of Canada would benefit by such an arrangement, whatever might be the result to individual interests. Now, would it not be in order for the *Iron Trade Review* to adopt for a brief spell, that degree of frankness for which it so highly commends us? We would be pleased if it would condescend to come down from its lofty pinnacle of patriotic virtue to *hard pan* and favor us with an unbiassed opinion as to how Mr. Morrison's tariff bill, in its entirety, would affect the interests of the United States as a nation. If the *Review* were quite unprejudiced by local interests we think it would agree with us in the belief that the benefits to accrue from reciprocity in iron ore and coal between the United States and Canada would be very evenly shared by the two countries.

Want of space compels us to hold over for our next issue an interesting article by Mr. E. J. Ball, Ph. D., London, England.—"Notes on the Progress of Mining in Europe."

THE PHOSPHATE TRADE.

Since our last report on the phosphate industry of Ottawa county the transportation of ore from the mines to the railway terminus at Buckingham, and thence to Montreal over the Canadian Pacific Railway, has been pushed with great activity. The Rivière du Lièvre, dotted with ore vessels plying between the mines and the landing at Buckingham, presents a busy scene, and although there has been a large accumulation of ore since the close of navigation last year the increased carrying facilities on the river insure its delivery at point of shipment early in the season. As will be seen by our statement of shipments for May, some phosphate was forwarded from Montreal during that month to Liverpool and Hamburg, the amount, however, being but 1,562 bags ground phosphate and 737 tons crude. The first shipment for the year was on May 12th per SS. *Kehweider* to Hamburg. Last season the first shipment was to Liverpool per SS. *Sarnia* on May 21st, and the shipments for the month aggregated 1,393 tons, all crude. Thus it will be seen that between May 21st and 31st in 1885 the shipments of crude phosphate exceeded those of this year from 12th to 31st of May by 656 tons. This is accounted for by the present unsettled condition of the fertilizer market in England and on the Continent and by the fact that miners show no desire to sell and are not offering their output at present prices. There has been some uncertainty with regard to ocean freight, which has, in a measure, checked the forwarding of phosphate. Miners are not uneasy as to the prospects for the future and are sanguine that the fertilizer market abroad will recover later in the season and that better prices will be obtainable for Canadian phosphate, which is always more or less in demand. They are also hopeful of securing lower freight rates than are being offered at the present time, and they have good reason to expect this. Meanwhile the ore is finding its way to Montreal in large quantity and will there remain ready to be forwarded when sold. It is not improbable that in future a large quantity of ground phosphate will be shipped to Hamburg and other European ports, and that there will henceforth be a large and increasing demand in the United States for Canadian phosphate in a ground state is already assured.

The Portland (P.Q.) Phosphate Mining and Milling Company have taken orders that will tax their mill to its full capacity for several months. This company's mill is one of the most complete of its kind in America and performs its work in a most satisfactory manner. The several operations to which the ore is subjected reduce it finally to an impalpable powder and by ingenious contrivances a large percentage of the foreign matrix is expelled, thus bringing up the percentage of tribasic phosphate of lime several units. The mica extracted in this manner is saved and sold at a fair price. In the last issue of the REVIEW we reported sales of 4,000 tons of ground phosphate for the Buffalo, Cleveland and Chicago markets. This, according to newspaper reports, has been magnified to 10,000 tons, but we have received no verification of these figures and are not inclined to think that any such quantity has been sold. This would represent quite one-third of

the entire year's production, besides which the capacity of the mill is only 40 tons per day, and if worked night and day it could not grind 10,000 tons in less than six months, all things considered.

THE MINES.

The force of miners employed in the *du Lièvre* district has not varied since the winter and the mines are yielding ore in abundance. *High Rock*, the *Union* mines, the *North Star*, the *Little Rapids* and the *Emerald* have large reserves of ore in sight and at other mines in the district important developments have been made. At the *Glasgow-Canadian* mine in the Township of Derry, the shaft is now down 140 feet cutting two parallel veins, one of green and the other of red and green phosphate, aggregating about six feet of mineral. The ore is of very high grade and appears to be comparatively free from impurities. Another instance of successful deep mining is at the *Battle Lake* mine where a large body of ore has been laid bare in the bottom of the main shaft. The ore here is also very pure and the manager is of the opinion that all the small veins in the vicinity of the shaft are feeders to this ore body. This last mentioned mine is in the Township of Templeton and has recently been acquired by the Anglo-Canadian Phosphate Company. The McLaurin mine in Templeton continues to occupy a place on the list of heavy producers, and many less important mines in the County of Ottawa are contributing to the output of the district.

Important mining operations are going on at the phosphate mines in the Perth district. Messrs. Wilson & Green, of Montreal, are opening up a very promising location in North Burgess in the interest of an English company. Suitable machinery has been erected on the property which, it is expected, will develop into a rich and valuable mine. The Anglo-Canadian Phosphate Company are also preparing for extensive operations on the tracts of phosphate land they have acquired in this district. A much larger quantity of phosphate will be forwarded from the Perth district during this season than was forwarded last year.

Phosphate Quotations.

Comparatively little phosphate has yet been sold for shipment and owners are holding back. Shippers report that at the prices asked by miners, little business can be done. Miners, on the other hand, cling to the belief that prices will stiffen, and are not disposed to sell at the present ruling quotation of *one shilling* for 80 per cent. with a fifth of a penny rise. London brokers report that they can sell Canadian mineral phosphate at 1s. for 80 per cent., ex ship London or Liverpool, and the lower grades, viz., 75, 70 and 65 per cent., at correspondingly lower prices. South Carolina, and in fact all mineral phosphates, have been selling at lower prices than last year, notwithstanding that manufacturers are delivering largely to farmers. The present sluggish condition of the market in raw material is partly due to the season being a late one.

PHOSPHATE SHIPMENTS FROM MONTREAL FOR MAY 1886.

Date.	Vessel.	Destination	Shippers or agents.	Tons.
May 25	S.S. Oxenhalome	Liverpool.	Wilson & Green....	387
"	"	"	Lomer, Rohr & Co	350
May 12	S.S. Kehweider.	Hamburg.	W. M. Knowles	*1562 bags

*Ground phosphate.

Ocean Freight.

Shipping brokers of Montreal expressed some uneasiness after the opening of navigation in the St. Lawrence, on account of apparent uncertainty of freight rates for phosphate transportation. This, however, appears now to have been unfounded, as we learn of shipments having already been made at three to four shillings per ton to Liverpool, and future shipments have been contracted for at similar rates. The ruling ocean freight rate for phosphate for this season will, in all probability, be much the same as for 1885, viz: about five shillings and sixpence per ton.

Villeneuve Mica Mine.

During the past month the British and Canadian Mica and Mining Company have been actively opening up this valuable property and constructing a good waggon road from it to the Rivière du Lièvre. A commodious cutting-house has been established by the company in Buckingham Village, to which the mica is forwarded from the mine in sacks after having been carefully examined and split into convenient thicknesses. Experienced cutters have arrived from Franklin, North Carolina, until now the headquarters of the mica industry, and a number of boys and women are employed to split the mica for the cutters and to clean it when cut into sizes preparatory to sorting and packing it into 1 lb. packages for the market. The daily production of the *Villeneuve* mine will soon reach one hundred pounds of merchantable mica, which will be considerably in excess of that of any other individual mica mine on this continent. We purpose giving a full description of this mine in our next issue.

Oil Discovered.

Some excitement has been caused by the discovery of oil wells four miles from Shequandah on Grand Manitoulin. On May 17th, while a number of men were boring under the supervision of Mr. W. Thomas Newman they struck oil at a depth of 58 feet. It spouted out in a clear stream over the heads of those who were drilling. They continued boring, and at a depth of 75 feet came upon a vein of mineral water, iron and silt, from which there was a strong flow of gas. Mr. Newman then proceeded to Toronto, taking samples with him, and has since purchased tanks and pumps and will put down the latter as quickly as wells can be bored. Upwards of 14 tons of machinery are already on the ground and it is the intention to continue boring to a depth of 300 to 400 feet. The oil met with at 58 feet is surface oil of a very valuable description and peculiarly suitable for machinery.

COAL IN FRANCE.—The output of coal in France in the second half of last year was 10,157,630 tons. This total presents an increase of 780,919 tons, as compared with the output in the first half of 1885. The production of coal in France for the whole of 1885 was 19,534,341 tons, as compared with 20,023,514 tons in 1884.

DISCOVERY OF QUICKSILVER MINES IN RUSSIA.—A very important discovery of cinnabar mines has been recently made in the mining region of the Don, Russia. The ore is stated to contain from 69 to 80 per cent. of pure mercury.

MINES NORTH OF LAKE SUPERIOR.

PORT ARTHUR DISTRICT.

Work was resumed at the *West End* mine (Silver Mountain) about the end of April and a tunnel started at the foot of the mountain towards the vein which will be utilized for drainage purposes. The vein proper has prospected well and promises to develop into a rich silver mine. Its outcroppings are visible for several feet along the surface.

At the *East End* mine work on the vein is progressing satisfactorily, and its owners are much encouraged by the manner in which the vein is developing. It is steadily improving in extent and richness, and several large nuggets of pure silver, one weighing three pounds, have been taken out. The richest part of this vein is not more than 1,000 ft. from the vein on which the Cleveland company did some prospecting, and the opinion prevails that, had better judgment been exercised, the Cleveland men would not have abandoned the location. A recent visitor to Silver Mountain reports having seen very rich silver ore taken from the drift where the Cleveland company formerly worked, and pronounces the vein at this point to be well impregnated with native and black silver.

Crown Point mine has come to the front and is likely to become one of the important producers of the district. The miners are working in two drifts, one at the base of the mountain and the other directly above it, both on the vein which is unquestionably a true fissure. The ore from the upper portion of the vein has been shown by assay to be very rich, but recent development has produced ore from the lower drift which is said to be much more heavily mineralized. A very rich streak has been encountered which shows abundance of silver and has created quite an excitement among the miners. As far as the vein has been worked on it shows silver well disseminated and occasional very rich streaks, some of the vein matter containing nuggets varying in size up to one and a half inch long. Most recent advices report that at the point of contact of three feeders with the vein proper much native silver is visible. This mine is owned by mining men of St. Louis and other western cities who have ample capital at their disposal. It is their intention to greatly increase the number of miners so soon as sufficient ground has been opened to admit of a larger force being employed.

On location "223," at the north end of Silver Mountain, a considerable amount of development work has been done with encouraging results. A tunnel has been driven for upwards of 400 feet and a shaft put down 40 feet. Native silver has been met with at several points and the present appearance of the vein has inspired its owners with confidence. Assays of the vein matter have given large quantities of silver and the location promises to increase in value as work progresses. About twenty miners are now employed on night and day shifts, but their work has been somewhat retarded by water, which is coming in very rapidly.

Latest advices from the *Beaver* mine report that the air-compressor and steam-drills were nearly ready to start work. The lighter parts had been brought on the ground, but the delivery of the heavier machinery would be delayed until the road to the mine, which was in an almost impassable condition, had been improved. A large force has been steadily engaged at the *Beaver* mine and a great deal of important development work has been accomplished.

Work at *Rabbit Mountain* mine is being energetically pushed and great results are anticipated after the mill has been in running order. The machinery is all on the ground and will be put in place so soon as the mill is erected, which is now rapidly approaching completion.

Recent work at *Silver Falls* mine has exposed a good-looking vein dipping to the north at an angle of 35°. The vein is 5 feet wide, is well charged with mineral and promises well.

JARVIS ISLAND MINE,

Thunder Bay District,

TO BE WORKED BY A NEW COMPANY.

In our last issue we published a letter from "A Miner" in which our correspondent referred to this property in the following words: "*Jarvis Island* was worked and tested to a depth of 130 ft. and found to carry native silver and silver ore, and when abandoned there was a good show of silver. The owners of the property intend, I believe, to start work again this spring." We are now in receipt of the report of the directors of the company, to be submitted to the shareholders at a meeting to be held in London, Eng., on the 15th inst. The report is as follows:—

"In placing the accounts before the proprietors, the directors have to announce that they have decided to make a change in the constitution of the Company.

Subject to the approval of the shareholders, they propose to dispose of the whole assets of the existing concern to a new Company, to be entitled, "The *Jarvis Silver Mining Company, Limited*," with a capital of 90,000 ordinary shares and 10,000 preference shares of £1 each; and it is proposed that of the ordinary shares ten fully paid shall be given for each £10 share in the existing Company.

This plan is in substitution of the recent proposal to raise capital by means of a development company, which would have involved the sacrifice of one-third of the Company's property.

The present proposal is more advantageous to the shareholders, who will have the first offer of the preference shares at such price as it may be decided at the meeting to issue them.

Since the meeting a report has been received of the rendering at New York of seven cwt. of samples of the silver ore (poor and rich) taken from the mine, with results that fairly confirm the assays of which you have been informed.

The actual result was 134½ dols. to the ton of ore, after deduction of the loss in extraction, which is of course greater in putting a small quantity through a mill, owing to the impossibility of making a perfect cleaning up.

The experience of the neighboring *Silver Islet* mine was stated to be that ore of 10 dols. value per ton, passed through the same kind of mill, yielded nearly half profit.

It is therefore evident that should sufficient ore be found, the *Jarvis* will prove a very valuable mine.

The evidence of miners employed when the mine shnt down is very encouraging, and all agree that when the mine was stopped for want of funds, by order of the board here, it gave every indication of proving most valuable.

The deepest working where the best ore was found was 146 feet, and as the water was easily kept down by a bucket worked by a horse, the unwatering with an engine and pump will only be the work of a few days.

The shareholders must be reminded that besides the island on which the rich ore was discovered there are 6,400 acres (freehold) on the

mainland two miles off, having much valuable wood, and several outcrops of mineral veins, embracing, moreover, one of the best natural harbors on Lake Superior, so that apart from the promising mine already opened, there is a substantial basis of value unburdened by debt.

It is proposed to wind up the present company and to appoint Mr. William Cash as liquidator at a remuneration of £100 for his services.

MINERAL RESOURCES

OF

NOVA SCOTIA.

Continued from page 5, Vol. 4, No. 4.

Iron Ores.

This, perhaps the most important of Nova Scotia's mineral resources, has not as yet received attention commensurate with its value. The ores are of the most varied species and frequently very pure. They are generally accessible, near water or railway transport, and none of them at any great distance from coal. Beginning at the western end of the province, titaniferous iron sand is met at St. Mary's Bay, and the trap rocks forming the south side of the Bay of Fundy yield abundant indications of specular and magnetite. At Clementsport and Nictaux are beds of red hematite and magnetite, formerly worked to a small extent in charcoal furnaces. From this point, as far west as Windsor, specular, red hematite and bog ores are found, but little is known of their extent or value. Similar ores, sometimes highly manganeseiferous, are found between Windsor and Truro, at Goshen, Maitland, Brookfield, etc.

The following analysis of limonite from the last mentioned place shows very pure ore:

Water.....	11.36
Silicious matter.....	1.54
Phosphoric acid.....	trace
Sulphuric acid.....	none
Magnesia.....	trace
Metallic iron.....	60.00

On the north side of the Bay of Fundy the limonite ores of Londonderry are well known. Their passage has been traced for fifty miles along the range of the Cabequid Hills, and they have been worked for many years at the Acadian mines. Large amounts of a variety of spathic ores are mined and smelted with the limonite, and a good grade of pig made, part of which is converted into bar iron, etc. There are two large blast furnaces, with rolling mills, foundries, etc., and from 40,000 to 60,000 tons of ore are annually smelted. The following analyses show the character of the iron ores of the Acadian mines:—

	Micaceous Hematite.	Limonite.
Per oxide of iron.....	96.93	82.65
Oxide of magnesia.....25
Alumina.....	.33	.56
Lime.....	.04	.15
Magnesia.....	.11	.10
Phosphoric acid.....	.07	.38
Sulphuric acid.....	.03	.02
Water hygroscopic.....	.03	.31
Water combined.....	.79	10.51
Insoluble.....	1.26	4.79
Metallic iron.....	67.85	57.85

SPATHOSE ORES.

Insoluble silicious matter.....	.47
Calcic carbonate.....	.59
Ferrous.....	69.20
Manganous.....	1.37
Magnesian.....	28.73
Ferric oxide.....	.08

Iron ores are known at Pugwash, Wallace, Joggins, Clark's Point, etc., north of the Cobequid Hills.

The Londonderry iron ore bearing ground passes north of Truro and extends into Pictou county, and may be said to terminate at Cape George in Antigonish county. On entering Pictou county near the line of the Intercolonial railway are met widespread indications of specular ore, which, at several points, show veins of workable size. This specular ore ground extends to the head of the East River, a distance of about twenty miles, and carries ore veins which attain a thickness of fifteen feet. South of this band are deposits of limonite ores, which, however, are yet little known. In the vicinity of Springville, between the specular ore and the Pictou coal field, are large and valuable beds of limonite, sometimes highly manganiferous, and bedded red hematites attaining a thickness at some points from 20 to 40 feet. On Sutherland's river these ores approach the eastern end of the coal field, one ore bed, fifteen feet in width, being not more than two miles from Vale colliery. An exposure of a bed of red hematite three feet thick at Arisaig marks the termination of this district, which is fifty miles long, and attains a maximum width of six miles. Clay ironstone is met at several points in the Pictou coal field and between New Glasgow and Pictou.

The following analyses serve to show the character of the Pictou iron ores:—

	Limonite	Clay Iron Stone.	Specular.	Red Hematite
Water.....	7.702	2.132
Iron Peroxide..	87.925	45.361	97.52	65.26
Alumina.....	Trace..	16.962	5.59
Silica.....	3.000	.780	3.20	25.68
Manganese Binoxide.....	Trace.....
Lime.....	".....	Trace..	.91	1.88
Magnesia.....	.500	1.655	1.05
Sulphur.....	Trace..	.612	.06
Phosphorous....	".....	Trace..	Trace..
Metallic iron...	65.540	35.000	68.33	43.40
Carbonic acid...

The following analyses is of the spathic ore from Sutherland's river:—

Sesquioxide of iron.....	20.52
Carbonate of iron.....	57.40
" of manganese.....	8.29
" of lime.....	4.02
" of magnesia.....	5.66
Silica.....	2.38
Moisture.....	1.43
Sulphur.....	none
Phosphorous.....	none
Iron.....	42.07

In Pictou county the conditions for making iron and steel cheaply are most favourable, as within a few miles are collected numerous iron ores, fluxes and good furnace fuels, and there is railway and water communication with all parts of the Dominion.

In Cape Breton indications of valuable iron ores are frequently met, but hitherto there has been little inducement to test or develop them. Near East Bay a bed of red hematite ore from 4 to 13 feet wide has been traced several miles, specimens of which have been analyzed as follows:—

Iron peroxide.....	85.057
Silica.....	5.130
Sulphur.....	.075
Phosphoric acid.....	.032
Metallic iron.....	57.526

Gold.

The auriferous district of Nova Scotia stretches in an irregular band along its shore. Its area is estimated at about 3,000 square miles. The gold mines are scattered

through this band, the greater number being to the eastward of Halifax. The auriferous district is found to contain numerous veins of quartz from one inch to six feet in thickness, running continuously, in many cases, for miles. Nearly all these veins contain gold, but, as elsewhere, only a certain percentage of them are rich enough to work. They carry the gold in visible grains imbedded in the quartz, and in the various sulphides of copper, lead, iron, etc., invariably found in them. The width of the veins usually worked varies from four to twenty inches, but in some cases they are found to be highly auriferous when much wider.

These veins carry gold in amounts varying from a trace up to several ounces, and in common with auriferous veins of other countries, frequently present it in the form of "pay streaks" or rich zones in the vein. These "pay streaks" are of varied width and depth, and are frequently very rich. In the Sherbrooke district one of these deposits was followed to a depth of 600 feet. The quartz surrounding these richer portions of the veins varies in value from three to ten dollars a ton. Other veins again show a uniform yield, not exceeding one-half to three-quarters of an ounce to the ton for long distances.

Among the more prominent districts at the present time may be mentioned the Salmon River mines. Here work has been carried on for several years on a vein of quartz from three to six feet wide. Several shafts have been sunk to a depth of about 150 feet, and ore has been extracted from a portion of a vein about 900 feet long. The quartz is crushed in a stamp-mill driven by water power and placed about a quarter of a mile from the mine. There are eight batteries, each holding five stamps, weighing about 700 lbs. each complete. The average yield from the quartz has varied between seven dwts. and one ounce to the ton. Owing to the size of the vein and cheapness of the water power crushing, this ore could be profitably treated even if the value of the gold yield fell to five dollars, or say twenty shillings to the ton. Since the opening of the mine 33,253 tons of quartz have been crushed and yielded 18,047 ounces of gold. This can be taken as a sample of others now working in the province, but it will be understood that the narrower the vein the richer its contents must prove, as the expense of mining increases rapidly with the greater amount of dead work. At Montagu, Rawdon, Oldham, Stormont, and Lake Catcha profitable mining has been carried on during the past year.

The Inspector of Mines, in his annual report, expresses the opinion that the great future of gold mining in Nova Scotia lies in the so-called "low grade" ores. In many of the districts are found wide belts of slate and quartzite, intersected by quartz veins, both the veins and rocks being more or less auriferous. Trials on a working scale have been made of such ores as they occur in the province, and the field appears even more promising than in any other gold mining country.

A Quartz Milling Company Starts in Nova Scotia.

A new and important enterprise has been opened in Yarmouth, N.S. The British American Manufacturing, Mining and Milling Company have opened their works and put in one of their new electric rotary crushing mills, under the superintendence of Mr. J. F. Wiswell, of Boston, son of the inventor. The mill is now in operation and will crush twenty tons of ore

per day, and it is claimed will save from twenty to forty per cent. more gold than the ordinary stamp mills now used in the province. This mill has been put up by an American company who make Yarmouth the headquarters of their operations in Canada. They will have their mills manufactured by the Burrell Johnson Iron Company and will supply them at short notice to any part of the Dominion. The company purpose taking interests in mining properties and aiding in their development, besides handling quartz to order at their mill. Several lots of ore are now in the mill awaiting treatment, and if the crusher saves as large a percentage as is claimed, the value of the auriferous deposits of the Province will be greatly enhanced. The new mill is formed of four heavy iron wheels running in a groove and giving a continuous crushing surface with much less expenditure of power than that required by the stamp mills. A constant current of electricity from a powerful dynamo prevents "sliming" and greatly aids the process of amalgamation. The amalgam can be drawn off from a quicksilver trap at any time without stopping the mill. The mill is the first of the kind ever put up in Canada, and has been proved in many gold districts of the continent.

CORRESPONDENCE.

IRON SMELTING IN CANADA.

ST. IGNACE, MICH., U.S.,
May 12th, 1886.

Editor Canadian Mining Review,

SIR,—I received, a few days ago, from a friend in Toronto, the intelligence of the unfortunate termination of Messrs. Parry & Mill's enterprise in the blast furnace line, in the Madoc district; I also received a copy of the *Hamilton Times* containing a criticism on Mr. Bartlett's book (recently published by Dawson Bros, Montreal), and as it is evident, from the information given in your March number of the *REVIEW*, that Canadian mines and minerals are at last beginning to receive recognition of their value, I have thought that a letter from one deeply interested, as I am, in the prosperity of the country, and well acquainted with its peculiar difficulties in this department, might be of value to your readers.

The *Hamilton Times* styles, and perhaps rightly, the production of iron, "One of Canada's lapsed industries." Why is it so? Mr. Bartlett lays the blame on defective legislation. Let us see if there is not some other cause. In the case of Mr. Van Norman, detailed in Mr. B's work, we find that he succeeded well in stove and brittle casting, making about 3 tons per day from bog iron ore. He afterwards purchased the Marmora works where he had a totally different ore which he knew nothing about, and so situated that it cost perhaps \$10 per ton to get it to market. Success could hardly be hoped for under such conditions, and no government would be justified in protecting such an industry. Mr. Van Norman's next effort was in a branch of blast practice, which was then in its infancy, namely, making car-wheel iron. He worked along evidently for some time, making no test of his product, till he had accumulated 400 tons, which, on being shipped to the car-wheel foundry, was found useless for that purpose. Had Mr. V. known anything about the business he would have found this out by the first cast taken from the furnace, and would then have either abandoned the works or have endeavoured to find some

ore which, mixed with his own ore, would give the required properties to the metal; in either case he would have avoided the loss incurred in making 400 tons of a product which had to be sold for less than its cost; this case is, I think, also beyond the help of legislation, and forms a fair example of these enterprises. Let us take the last case, that of Messrs. Parry and Mills. These gentlemen may, or may not, have understood the business in which they embarked. I am informed that owing to an unfortunate error of judgment they met with a heavy loss in the destruction of a portion of their plant; be that as it may, it is evident that they went into the business with insufficient capital, and that even had they completed their works they could not have withstood the slightest failure in the working of their furnace at the outset. My own experience in blast furnace work has taught me that to start a furnace in a new district with untried ores, it is necessary that the parties engaged in it should possess sufficient capital to enable them to stand from six to nine months unsuccessful running till they have learned how to mix their ores and what ores to use, in order to obtain the desired product. It is possible that they may succeed from the start, but the probabilities point the other way, and their iron for some time may be saleable only at the market price of ordinary coke iron (I am of course taking it for granted that a furnace located in central Canada would make charcoal iron) and they may even have trouble in producing that. None but the initiated can understand the difficulties in the way of making car wheel iron so as to obtain a product of the required strength which will not show "skin-chill," "chill-cracks," "manganese chill," etc., etc. And here is where, in my opinion, the Government might fitly, and at a very trifling cost to the country at large, assist the struggling furnace man by giving a sufficient bonus on the manufacture for a limited time till the work had passed the experimental stage, care being taken that this experimental stage was not fraudulently prolonged for the benefit of unprincipled parties interested in the enterprise.

The establishment of a bureau of mining and mineralogy is also an important step in the right direction, which, besides being an assistance to the mining industries, would help to remove one of the greatest difficulties in the path of Canadian iron manufacture. It is well known that there is an abundance of magnetic ore in Canada, it being easily discovered and traced out by the use of the dip needle, but to run a furnace successfully on car-wheel iron, it is necessary to have a mixture of magnetic, specular, and hematite ores. Respecting the deposits of the two latter ores, but little is known so far as I have been able to ascertain. I know of some deposits in Frontenac County, having examined some of them, as well as in other districts, but nothing sufficiently definite to satisfy a furnace man is yet known about them; so that until the mining bureau or some other agency throws light on the subject it will not be easy to get practical men to invest money in that line (furnace building). As regards the tariff, I consider protection an absolute necessity, but it may be over done and so induce rash and ignorant speculation.

SAMUEL D. MILLS,
Supt. Martel Furnace Co., St. Ignace,
Mich., (late of Kingston, Ont.)

GRANITE CREEK,

(British Columbia.)

LETTER FROM THE GOLD COMMISSIONER.

Promising Quartz Ledges in the District.

The following letter from Mr. G. C. Tunstall, addressed to the Minister of Mines, contains a warning to those who may be tempted to try their luck in the Granite creek diggings:

GRANITE CITY, April 21st, 1886.

The Honourable the Minister of Mines, Victoria, B.C.:

SIR,—I have the honour to inform you that the prevailing freshet on Granite creek and the Similkameen and Tulameen rivers has almost entirely suspended mining operations. The period between the present high water and the summer freshet will be of too short a duration to justify claim owners to repair their dams and flumes to again run the risk of having them swept away. The other creeks are still so much encumbered with ice and snow that it is probable no mining activity will be exhibited before the middle of June, or perhaps later.

This is a very unfortunate state of affairs for the district, as few of the new-comers can afford to remain idle, and many have left with reports of an unfavourable nature, calculated to encourage the belief that the mines are a partial failure. But confidence will be restored when the difficulties mentioned are removed.

Several promising quartz ledges have been taken up and recorded. The appearance of the ore is highly spoken of by persons experienced in that important branch of mining in Colorado and Arizona, and I think it would be advisable for the Government to have assays made *gratis* of the various samples I may forward for that purpose, in order to afford some definite idea of their value, and stimulate a search for the gold and silver bearing claims.

I have the honour to be, Sir,
Your obedient servant,
G. C. TUNSTALL,
Gold Commissioner.

The following extracts are from a letter of a more recent date from the Gold Commissioner to the Minister of Mines:

"I have the honour to inform you that a new creek named 'Boulder creek,' has been lately discovered. It crosses the Granite-creek-Nicola trail at a point about eleven miles north of this place (Granite City), and empties into Otter creek on the west side, near the head of the lake of that name.

FIVE PANS OF DIRT YIELDED FOUR DOLLARS. The prospect was obtained on a bench about thirty feet above the present channel. A number of persons have started with the intention of staking off ground.

* * * There are about

ONE HUNDRED AND FIFTY MEN

at work on the South Fork of Granite creek, concerning which sanguine expectations are entertained. The Spokane company are down 18 feet and daily expect to reach bed rock, the water is still at a high stage, and mining on the rivers and Granite creek is almost entirely suspended."

AUSTRALIAN COPPER AND TIN EXPORTS.—During the month of March, the following were among the exports from Melbourne, Adelaide, Sydney, and Queensland to Great Britain: Copper, 800 tons; copper ore, 300 tons; and tin, 500 tons.

The Australian Gold Supply Continues to Decrease.

The result of gold mining in the Victoria gold fields for 1885 shows an output smaller than that of any year since 1852; that is to say, since within a year of the discovery of gold in that quarter. The year's product, as abstracted by the London *Mining Journal* from the official returns, is given by quarters as follows, we adding the value at the rate of £3 17s. 9d. per ounce or \$19.43 per ounce:

		ozs.	dwt.	grs.
Quarterly	March 31	192,438	11	15
"	June 30	154,375	15	10
"	Sept. 30	176,159	2	21
"	Dec. 31	181,582	16	6
Total weight		735,218	6	4
Value			\$14,285,285	

For the last quarter we append the table compiled from the estimates of ten mining registrars by districts:

Districts.	Alluvial.	Quartz.	Totals.
	ozs. dwt. grs.	ozs. dwt. grs.	ozs. dwt. grs.
Ballarat.....	34,500 13 18	22,741 11 21	57,242 5 15
Beechworth....	8,412 15 1	5,300 3 12	13,722 18 13
Sandhurst.....	1,372 12 13	47,562 13 21	48,935 6 10
Maryborough...	13,868 4 15	4,759 16 21	18,628 1 12
Castlemaine...	5,775 3 21	12,821 14 20	19,596 18 17
Araucan.....	4,994 14 20	2,040 17 14	7,035 12 10
Gipps Land....	2,054 17 4	14,366 15 21	16,421 13 1
Grand totals..	71,989 1 20	169,593 14 10	181,582 16 6

The following table shows the product of the same fields during the last ten years for the quarter ending December 31st, of each year:

Year.	Yield.	Year.	Yield.
	ozs. dwt. grs.		ozs. dwt. grs.
1876.....	228,640 5 1	1881.....	225,071 14 19
1877.....	218,159 3 14	1882.....	236,303 1 17
1878.....	206,058 0 8	1883.....	190,931 17 18
1879.....	209,411 7 7	1884.....	200,789 16 13
1880.....	228,628 8 20	1885.....	181,582 16 6

Thus, it is to be seen that there has been a decrease in the same quarter from that of 1880 of 47,045 ounces. The dividends paid by incorporated companies aggregated about \$2,885,000. This was exclusive of a considerable amount paid by privately worked enterprises that make no report of dividends.—*F. & M. Record.*

A Productive Australian Gold Mine.

The Long Tunnell Gold Mining Company, of Gipps Land, Colony of Victoria, was first registered in 1863. In 1867, the present general manager, Mr. Ramsey Thompson, was appointed the engineer and superintendent of the enterprise. Underground workings by tunnel, with shafts therefrom and various levels at different depths, are very extensive, while a costly plant, of the most improved character, has been provided, including pumping machinery. The first dividend was paid in 1865 of \$5 per share on 2,400 shares. Ever since December 1869 or for seventeen years, this quartz has averaged 1 oz. 11 dwts. 17.24 grs. per ton, and at this time there is enough of similar quartz exposed to keep a 40-stamp mill running for five years. In these seventeen years the amount of quartz milled has aggregated 289,639 tons 10 cwt. with a yield of 459,767 ozs. 8 dwts of gold of the gross value of \$8,102,000. Out of this the shareholders have received \$4,884,000 or \$2,000 per share. Two items of heavy expense are fuel and mine timber which have to be brought some distance and have involved the construction of fourteen miles of tramway amid precipitous mountains with steel, iron and wood rails.

A 9,000-pound mass of tin ore was recently exhibited at a smelting works in New York. It was taken out of a 29-foot vein in the well-known Etta tin mine in the Black Hills.

DISCOVERY OF GOLD IN PATAGONIA.—A gold fever is raging in the Argentine Republic in consequence of the reports of the discoveries of the precious metal in Patagonia.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

THE ROYAL SOCIETY OF CANADA held its annual meeting on the 25th ult. and two following days. The meeting was the most important and interesting yet held by that Association, with regard to both the number and the kind of the papers presented to the various sections. There can be no greater evidence of the usefulness of the Society than the vast amount of work accomplished during the past year under its auspices. Single stars which before shone in solitary splendor in the scientific or literary firmament of Canada now emit a dazzling light when clustered in a constellation; and individual abilities which were not wanting in our young country, now roused to emulation, and encouraged by the facilities afforded for an exchange of ideas, produce a hundredfold to the great benefit of art, science and industry.

THE SCIENTIFIC SECTIONS deserve much more than a passing notice. We intend giving a review of the different papers, which cover a wide field of knowledge. Botany and geology, especially geology, gave valuable contributions. Chemistry and physics, though they received less attention, were not neglected, and it was a rare treat for the student of mathematics to witness the ease with which important questions in the higher branches of that science were treated. Canada, and our province in particular, may feel proud of its professors, and it has been said with truth that Ontario is equal to any other province or state in the attention devoted to mathematics in its colleges and schools.

IT IS SURPRISING, however, to see how little interest is manifested in the work of the Royal Society. Though the press of the city has displayed a most commendable zeal in calling public attention to the important business transacted at the meetings, the members of the Society were practically alone to profit by the information given in the various papers. Many reasons might be given to explain, though not to excuse that indifference of the intelligent public of Ottawa. One will be sufficient. The meetings are held in the Parliament buildings at a time when, the House being in session, a vast amount of noise and bustle must necessarily drown the tranquil echo of scientific discussion. Besides, the rooms in which the meetings are held are not those to which the public usually have access, and the sections are so frequently forced to flit from one room to another as to discourage any but the true lover of science and literature. It is, therefore, much to be hoped that the Society may find in some of our large Institutions suitable halls easy of access to the public, and where better accommodation can be had for the discussion of scientific and literary topics.

A MOST HAPPY CHOICE has been made in the person of the very Rev. T. E. Hamel, the new President of the Royal Society of Canada. This gentleman, one of the most distinguished members of the Roman Catholic clergy of Canada, has been for many years Rector of Laval University. He is not only remarkable for his lofty scientific attainments, but is also one of those liberal-minded men whose unselfishness, affability and modest ignorance of personal merit will have the natural effect of removing pre-

judices, and bringing the various sections of the community to work harmoniously together for the common good.

ARTESIAN WELLS.—The fifth annual report of the U.S. Geological Survey contains a lengthy paper on the geological and other conditions necessary to success in boring artesian wells. Some facts not very generally known are mentioned in connection with the subject. Crystalline rocks, although frequently containing fissures and channels near the surface, are not to be depended upon as water bearing beds; for these crevices generally disappear at greater depths, and the strata become impervious. Water sometimes makes its way through the fissures of limestone; but, as in granite, these fissures become smaller in proportion to the depth of the rock, until at length they are entirely closed. However, quite a number of important artesian wells spring from a limestone bed. The most porous, and therefore the best water-bearing beds are formed by the sandstones. The best confining beds is a thick layer of fine, unhardened clay. The lower confining bed does not require to be as completely impervious as the upper one, for the leakage will be caught by other layers farther beneath. But the upper confining stratum must be absolutely impermeable, or the great upward pressure will cause the water to escape. Water itself is capable of acting as a confining bed in many cases. If some of the common underground water, in which ordinary wells have their source, lies between the artesian well and its source, at an elevation equal to that of the fountain which feeds the water bed, no leakage can be caused by the upward pressure, even though the upper confining stratum be permeable. If the underground water is higher than this fountainhead, it will penetrate the water-bearing bed, and cause a stronger flow through the artesian well. But if the underground water be situated lower than the fountain, leakage will occur if the upper confining bed be not impermeable. From the use here made of the term fountain, many have been led into the mistake of thinking that the water-beds, from which spring artesian wells, are fed by surface lakes or subterranean reservoirs. The former theory is untenable since the bottoms of surface lakes are impermeable. If this were not the case how could lakes retain their water? Neither are underground pools the feeders of water-beds. When we speak of the fountain head of a water-bed, we mean simply the water absorbed by the highest portion of the bed at or near the surface which is constantly flowing downwards and as constantly receiving a fresh supply from above.—D. V. P.

CAVERNS.—It is already eight years since the famous underground caves at Luray, in central Virginia, were discovered, and yet information regarding them is not very widely spread. They are hollowed out of Lower Silurian limestone of the Tertiary period, or perhaps an earlier date. At first there was probably but a small fissure in the rock, through which flowed water containing carbonic acid in solution. This stream gradually wore away the limestone in various directions being aided in the erosion perhaps, by sand which it carried in its waters. Naturally, as the supports were hewn away from the bottom, large masses would fall from the top, giving the incipient cavern a lofty altitude. After the water had done its work, it seems to have been turned into another channel by some geological change. Now the period of ornamentation began. The surface water percolating through the limestone, and becoming charged with carbonate of lime

dropped to the floor or evaporated on the roof, forming beautiful stalagmites and stalactites, which being constantly increased by new formations sometimes extended to meet one another, and form whole sheets of carbonate, resembling the most delicate drapery. After this it appears that the cavern became again a drainage channel, this time for the corrosive mud of the glacial period. This mud stained the sides of the cave and its newly formed stalagmitic columns. Its corrosive action is visible in the various forms into which it carved and twisted these columns. At the end of the glacial period the channel was once more free, and new calcite pillars and draperies were formed. When the cavern was discovered in 1878, the skeleton of a human being was found in a secluded part of it. But the hopes of our progressive (?) geologists were not yet to be fulfilled by the discovery of a secondary or tertiary man, for the tufa in which the remains were found was evidently of recent origin. The largest of the halls in the cave of Luray is called the Cathedral. It contains a massive block of stone, resembling in shape an organ. Attached to this are eleven parallel blades of stalactite, each of which when struck gives a different note, so that tunes can be played on them. The Cascade, the Angel's Wing, and the hollow column, the interior of which may be ascended to a height of sixty feet, are among the objects of interest to visitors. The fauna of the Luray caves is not very numerous, the principal specimens being some spiders and a myriapod. The writer in the *S. M. Quarterly*, to whom we are indebted for all the above mentioned facts in this connection, says that no other cavern in the world is so completely decorated with stalagmitic formations.—D. V. P.

SCIENTIFIC NOTES.

WATER.—The best means of purifying water suspected of containing those micro-organisms, which produce so many epidemic diseases, is to filter it through vegetable carbon of lime.

GEMS.—In view of the approaching sale of the crown jewels, by the republic of France, it is interesting to note that two of these are of American origin, a very beautiful amethyst and a sapphire, both of which were found in New Carolina.

THE DAWSON PRIZE, offered by Dr. G. M. Dawson, F.R.S.C., acting Director of the Geological Survey, to the Mineralogical Society of the College of Ottawa, for the best essay presented to the society by a student of the Institution, has been awarded to Mr. Walter A. Herckenrath, of Mamaroneck, N.Y. The successful essay was a thesis to establish the "Absence of man during the Tertiary age."

OZONE.—Sick rooms and hospitals, theatres and other places of public resort, can now be easily ventilated by the ozone machine, which is operated by electricity. The purifying qualities of this gas are thus practically applied where they are much needed. Large bleacheries are also beginning to make use of the well known but hitherto unused bleaching qualities of ozone.

SULPHUR.—Prof. Bloxam, the distinguished chemist, has called attention to a fact not generally mentioned in text-books, viz., the crystallization of sulphur from a solution in hot alcohol. This is important, when we consider that in practical organic chemistry alcohol is frequently passed through rubber corks. If a

rubber cork be boiled for fifteen minutes with alcohol, the solution, when cooled, will deposit white, transparent, prismatic crystals of sulphur.

GAS.—Dr. Auer, of Paris, has made an addition to the Bunsen's burner, so familiar to every laboratory student, in the shape of a small conical cylinder, made of cotton or woollen fabric, previously saturated with nitrate or acetate of lanthanum and zirconium, or yttrium and zirconium. When the gas flame passes into this cylinder it develops considerable heat, and soon becomes incandescent, giving forth a steady and brilliant white light. This new invention is likely to revolutionize the gas industry.

TARIFF.—All who are interested in the progress of practical science in our Canadian schools and colleges must commend the wisdom of the Dominion Government, in replacing scientific apparatus on the list of articles admitted free of duty. This change, it is believed, is largely due to the representations made by the various educational institutions, who proved that it would be a great hindrance to the prosecution of scientific studies, if they were obliged to pay a high duty on instruments, many of which can be manufactured only in one or two cities of Europe.

CYANOGEN.—Prof. Dixon, M.A., in a paper read before the Chemical Society of London, compares the results of experiments in the combustion by electricity of cyanogen and oxygen with those obtained from the combustion of carbonic oxide and oxygen. As the presence of aqueous vapour in the latter case increases the force of the explosion, he was led to think that his failure in previous experiments with the former was owing to the absence of moisture. He afterwards discovered that it was the insufficient temperature of the electric spark passed through the cyanogen and oxygen, that prevented the combustion, and that moisture, instead of increasing the explosive force in this case, diminished it. The reaction of carbonic oxide with oxygen, when a platinum wire is heated to redness in a mixture of the gases, is entirely similar to that produced by cyanogen with oxygen under the same circumstances. In one the cyanogen, and in the other the carbonic oxide combines with the oxygen without visible flame. In the case of cyanogen, however, the characteristic orange vapour is generated in the tube.

METEORITE.—Mr. Orville A. Derby, who was recently charged with the duty of examining the famous Santa Catharina meteorite, preserved in the Brazilian National Museum at Rio Janeiro, has given to the world through one of the scientific periodicals, some account of his labours, in advance of the memoir about to be published. On the surface of this meteorite, when discovered, there was a strong crust, which M. Daubree, a French mineralogist, who studied the meteorite, thought to be of terrestrial origin. He called it limonite, and supposed that it had been produced by the oxidation of the iron after its fall, and the adhesion of fragments of the granite among which it was found. Mr. Derby claims that this crust, instead of being earthy is an essential part of the meteorite, and a confirmatory evidence of its origin. The crust consists of two parts, the one granitoid, the other porphyritic. The former is composed essentially of olivine, in glassy, crystalline fragments, and of small grains of plagioclase feldspar, with veinlets of black limonite running through the whole. Under a microscope the granitoid resembles porphyry. No grains of metallic iron have been detected in this part of the crust, but its slightly magnetic

quality causes suspicion of their presence. The porphyritic portion of the crust resembles the masses of limonite found in decomposed granite. It consists of grains of olivine mingled with rare fragments of plagioclase. It differs from the granitic form by the feldspar's being clearer and more transparent. Whatever opacity does exist is owing to the vitrification of the margins of the grain, and not to decomposition. To ascertain whether, as he thought, the porphyritic rock was produced by the partial fusion of the granitoid, Mr. Derby performed a synthetic experiment. Taking quartz to represent the infusible, and labradorite the fusible material, he fused together unpowdered fragments of these minerals with iron filings, and some magnetic pyrites. The product of the incomplete fusion resembled very much the meteoric crust, the principal differences being that the glass was clearer, and the grains of feldspar not vitrified, more opaque. It is proved, therefore, that the Santa Catharina meteorite is a mixture of metallic and silicious elements, the stony part being a new type consisting of olivine and plagioclase. The partial vitrification of the stony portion is a sure proof of the meteoric origin. The presence of silicates forming a crust of low conducting power around the iron, accounts for its low magnetism. It was this that led Becquerel to think that the iron had crystallized at red heat, a fact at variance with the well known properties of meteorites.

BOOK NOTICES.

ELEMENT OF THE THEORY OF THE NEWTONIAN POTENTIAL FUNCTION, by B. O. Peirce, Ph. D., Assistant Prof. of Mathematics and Physics, in Harvard University; 154 pages, large 12mo. Boston—Ginn & Co.

The preface states that the book is intended for "Readers somewhat familiar with the principles of the differential and integral calculus, but unacquainted with many of the methods commonly used in applying mathematics to the study of physical problems." In this respect the book supplies a long-felt want, and gives to those wishing to make a thorough study of physics, especially of those branches in which higher mathematics are used, the most necessary and practical applications of mathematics to physics. In this book of 154 pages are gathered together methods that the student would have to seek out by tiresome search in many different volumes. Numerous exercises are given which will enable the student to retain firmly the methods studied. The book is printed with the taste and neatness characteristic of the textbooks of Ginn & Co.

ELEMENTARY CO-ORDINATE GEOMETRY, FOR COLLEGIATE USE AND PRIVATE STUDY, by William Benjamin Smith, Ph. D., Professor of Physics, Missouri State University. 8vo., 280 p. Boston—Ginn & Co., 1886.

The student, who, attracted by the title of this book, would attempt to master it, with the ordinary amount of knowledge derived from an elementary course of algebra, geometry and trigonometry, would surely be disappointed. The motto, "maximum reasoning, minimum reckoning," chosen for this work, is not the passport of the average student of schools and colleges. But to him who is already familiar with mathematical reasoning, for whom ordinary algebra at least has no mysteries, and who is

able to devote a few hours each week with or without the assistance of a teacher, to the study of analytical geometry, the present work will prove a most efficient guide. Mathematical precision, enhanced by the use of abbreviations, and perhaps even a little exaggerated by the introduction of new terms destined to replace long expressions is the characteristic feature of the work. Another feature is the beautiful selection and gradation of exercises which will prove a real treasure to the private student as well as to the teacher. Despite its title the work treats of many questions which are absent from the text-books now in use; and every question treated, thanks to the vigorous style of reasoning, and the elimination of details, receives a most complete elucidation. We commend this work to all those who understand the necessity of mathematical reasoning for the training of the mind.

NOVA SCOTIA.

Twelve tons of quartz from the Kemptville Mine were put through the mill the last week in May and yielded 21 ounces of gold.

It is stated that a company has been formed to test a lead of gold-bearing quartz which has been discovered in the vicinity of Bear River, Digby County.

A seam of coal which has been recently discovered near the head of the West River is said to be larger than any of the numerous seams known to exist in the Pictou coal fields.

A New Brunswick company has purchased a manganese mine on the East Mountain, Colchester County. Some development work was done last summer on this property which is situated within a few miles of the Pictou branch of the Intercolonial Railway.

The Salmon River gold mine gives constant employment to forty men and the monthly expenditure by the company is \$2,000. Eight batteries, with five stamps each, are now in operation, and the head of water at the mine is sufficient to run a mill of double that capacity. Two pumps, also worked by water power, are in operation night and day and keep the mine quite dry.

The air is thick with rumors of important sales of gold mining property and an immediate and extensive resumption of operations on "The Nova Scotia Central Railway." A glimpse of a \$50,000 bond and the fact that Herr Fink has proceeded to the United States to purchase a crusher, go to fix some of the reports in the land of facts and indicate a busy season.—*Bridgewater Times*.

Letters Patent of Incorporation have been granted to Joseph Robbins Kinney, J. R. Wyman, R. S. Eakins, A. W. Eakins and G. W. Johnson, all of Yarmouth, under the name of the "Kempt Gold Mining Company (Limited)." The capital stock is \$30,000, divided into 100,000 shares of 30 cents each, and the company's chief place of business, Yarmouth. The company is now working the *Reeves Mine*

and has already crushed 80 tons of quartz which yielded 114 ounces of gold.

QUEBEC.

We have received a handsome specimen of green phosphate taken from a large body of ore at the bottom of the main shaft of the *North Star* mine in Portland East. The shaft is down 300 feet and is the deepest in the phosphate district. The ore at this depth is of very high grade and peculiarly free from impurities.

Professor Chapman, of Toronto, has recently inspected the St. Onge gold mine in Beauce and has been very favourably impressed. Of it he says: "The permanent presence of gold in the mine is fully established, and every cleaning up shows no inconsiderable amount of it." Professor Chapman is of the opinion that the drifts are at present in what must necessarily be the poorest part of the mine, and that consequently, when less broken ground is reached, a large increase in gold may be legitimately expected.

The tramway, recently constructed at the *High Rock* phosphate mine in Portland West, has been in running order for some time, and is proving a valuable addition to the company's improvements. Eighty tons of phosphate are now shipped daily over the tramway from the mine to the river bank. The largest boiler in the phosphate district is now being delivered at *High Rock*. It has a capacity of eighty-five horsepower, and measures 13 ft. 6 in. long by 5 ft. 6 in. in diameter. It was made by W. J. Campbell & Co., of Ottawa, and will be used to run an air compressor and eight drills.

ONTARIO.

The town of Wingham now boasts of having the best salt well in the province. It was struck at a depth of 1,100 feet. The Canadian Pacific Railway Company have agreed to extend its line to Wingham on the condition that salt-works will be established in connection with the wells.

Work was resumed last winter in the old shaft at the Michipicoten Native Copper Company's mine. It is now down 450 feet, and a cross-cut is shortly to be started. A recent discovery of native copper, associated with native silver in a two feet vein, has excited new interest in the property.

The Perth district is again coming to the front as a phosphate mining section. The operations of the Anglo Canadian Phosphate Company and Messrs. Wilson & Green, of Montreal, have stimulated the industry in this locality, and prospectors are again busily at work. Some recent developments are of a very important character.

A valuable gold mining location has been taken up at Lake Osinawe, to the north of Thunder Bay. The formation is granite with a belt of talcose slate running through it in an easterly direction. This talcose slate belt is 20 to 60 feet wide, interlaminated with auriferous quartz. One of the quartz leads is 16 feet wide and increases in width as it juts into the lake. A quantity of the quartz, representing a fair average from this lead, has been assayed and found to contain 2.042 ounces of gold per ton. Other smaller leads on the location are rich in free gold.

BRITISH COLUMBIA.

Some of the claims on Granite creek yielded \$200 per day before work had to be suspended on account of the freshet.

Another gold-bearing creek has been discovered ten miles from Allison's emptying into the Semilkameen, and is reported by prospectors as showing good colours.

The Kootenay Mining and Smelting company have purchased a seven-eighths interest in Rainee's and Williams' claim on Lake Pend d'Oreille, and will put up a smelter immediately.

Quite a large number of Chinamen have proceeded to the Nanaimo Lakes *via* Harewood. The Mongolians have struck some bench diggings in the vicinity of the headwaters of the Nanaimo river.

Collin's creek, between Granite city and Otter Flat, shows good prospects and some coarse gold has been secured which is brighter in appearance than that on Granite creek. Those who have claims on the creek are more than pleased with the prospects.

Reports from Alberni state that fifteen Chinamen have been mining on China creek since last fall. Their force has been increasing every week and will soon number 100 miners, which is strong evidence that gold is being found on the creek in paying quantity.

Great confidence is expressed by some in the result of this season's work in the gold diggings at Granite Creek. At present the camp consists of about 800 whites and 600 Chinamen, and it is said that nearly all who intend leaving before the end of the season have already gone.

Advices from Granite city report a few companies at work on the south fork, about three and a-half miles above the city, where, it is expected, paying claims will be found. Portions of the creek at this point have been wing-dammed for the purpose of testing the gravel on bed-rock.

The freshet in the Semilkameen district has been very strong this season and will not allow full scope for work until the beginning of July. More miners are leaving the district than going to it, which is more from a knowledge that the season will be late than from being aware as to how the field will "pan out."

The New Brunswick Mining Company, one of the wealthiest organizations on the Tulameen, has begun operations on a 2,000 ft. claim. Large results are anticipated as the ground has prospected well. The Californian Company, also owner of a large extent of ground on the Tulameen, has resumed operations.

The ledge of the "Queen" quartz mine at Yale has increased in width from 5 feet to 8 feet and gives indications of being a true fissure vein. The gangue is composed of decomposed quartz and porphyry with galena, iron pyrites, magnesia and blende well disseminated through it. If the "Queen" develops well, and there is every prospect of its doing so, Yale will become an active mining centre.

The mining interests on Lake Kootenay are promising. Four or five galena mines have been worked all winter and a large quantity of

ore taken out awaits transportation. The construction of the Kootenay railway is looked forward to and as soon as it becomes a certainty mining in the district will be vigorously pushed. At the town of Radnaid several houses have sprung up in anticipation of the opening of the Goat river quartz mines.

It is thought that Otter Flat will become the chief mining camp of the Tulameen district. It is one and a half miles from Cedar creek, two from Collin's creek, three from Slate creek, eight from Bear creek, and fourteen miles from Champion creek. These are all gold-bearing creeks and tributaries of the Tulameen river. Otter Flat is six miles from Granite city and is at the junction of Otter creek with the Tulameen river.

A large number of miners have been attracted during the spring to the gold diggings on the Stewart river, a branch of the Zukon, and upwards of fifty started in April from Juneau. The route taken was from Juneau to Chileat, 75 miles, thence across the mountains, 35 miles, to a chain of lakes emptying into the Felly river. From this point they proceeded in boats to the Zukon river, a distance of 350 miles, and thence down that river to the Stewart river, the scene of the gold excitement.

UNITED STATES.

The Montana Copper Company, of Butte, Montana, a large producer last year, is now raising comparatively little ore.

The Lake Superior copper product for the first quarter of this year exceeds that reported for the same quarter of 1885 by 2,113 tons, of which the Calumet and Hecla furnished about 1,000 tons.

The Plymouth Consolidated Gold Mining Company produced \$155,192.39 in gold during January, February and March of this year, and paid three monthly dividends, aggregating \$75,000. The ore from the mine, situated in Amador county, California, yields an average of \$11 per ton, chiefly in the form of free gold. All the ore goes directly to the stamp-mills, of which there are two. The older and larger mill contains sixteen batteries of five stamps each, with one Frue Vanner to each battery. The new mill has eight batteries of five stamps and two Frues to each battery. The large mill is driven by Leffel turbine-wheels, with a pressure of eighty feet, and a consumption of 600 miners' inches of water. The smaller mill is driven by "hurdy-gurdy" wheels, with a pressure of about 550 feet and a consumption of 150 inches of water.

South American Mining Notes.

The *Amigo del Paris* says that gold mining has received so great an impulse in Atacama that there is no doubt this branch of mining will become the industry of the province. Large capital is required for the prosecution of this enterprise, and our miners are beginning to comprehend the truth. With capital, continues the paper in question, Atacama may become a second California for abundance of gold.

The *Constituyente* furnishes the following interesting statistics respecting the production of silver and gold in the Copiapo mineral districts in January: There were sent down to Caldera for shipment from Copiapo 2,032,991 grams of

silver, and from Pabellon 568,064 grams. The receipts in Copiapo of bar silver were 3,730 grams from San Antonio; 935,940 do. from Juan Godi; and 585,710 do. from Puquois. The receipts of gold were 14,242 grams in Caldera, and 2,410 grams in Copiapo. The totals are 7,126,434 grams of silver and 16,952 grams of gold.

The Veterana mine of the Quintana district is paying another dividend of \$400 per share. The steamer which sailed from Coquimbo on the 4th instant, shipped for Valparaiso 168 kilograms, 16 grams of bar silver, the production of this famous mine.

The net receipts of the Huanchaca mines in February amounted to one million dollars, Bolivian currency. Typhus and yellow fever are reported to be prevalent in the Huanchaca district.—*F. & M. Record.*

First Silver in Colorado.

The first discovery of silver in Colorado was accidentally made in Summit county, something in this way:

Some gulch miners from Blue river, hunting for deer in 1861, ran out of bullets, and happening upon what they took to be a lead vein, manufactured some from the outcroppings. A year or two later, happening to be in Nevada, they were strongly impressed with the resemblance between the silver-bearing galena ores of that State and the material in the mountains of Colorado, from which they had once manufactured bullets. They wrote to an old friend at Empire, advising him to go over and locate the once despised lead vein. He finally did so and named the vein *Coaley*. He, however, never made a fortune from his venture, his mine being too far away from the ore markets, and also over the range from them. But the incident led to the recognition of the silver ores of Clear Creek county and resulted ultimately in the developments that have built up so many towns and cities, and added so much to the wealth of Colorado.—*Leadville Herald-Democrat.*

MINING REGULATIONS

To Govern the Disposal of

Mineral Lands other than Coal Lands.

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed twenty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labour during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES, AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, &c., &c.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either braided, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with,—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein,—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section,—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers", is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

AUCTION.

Phosphate Lands.

NOTICE IS HEREBY GIVEN THAT about 14,500 acres of Public Lands, situated in the Phosphate region, in the County of Ottawa, Province of Quebec, will be offered for sale by Public Auction, at the

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

It has already become a well recognized fact that the Colonial and Indian Exhibition has been the means of bringing Canada forcibly to the notice of the old world, and her very creditable display of the resources of the Dominion has earned for her a prominent, if not a foremost, place among the British Colonies. Of all her exhibits, however, none appears to have attracted more attention, or created more astonishment, than has the display which represents our vast mineral resources.

Significant evidence that much benefit will accrue to mine owners and owners of mineral lands is in the fact that, since the opening of the Exhibition, we have been recipients of innumerable letters of enquiry from manufacturers and capitalists in all quarters of Great Britain and Europe, asking for information regarding the importance of the mineral deposits of the country and the capabilities of the mines in operation.

In order that such enquiries may be replied to in an intelligent manner, it is absolutely necessary that those people who are most concerned in the development of Canada's mineral resources and the expansion of the markets for the product of her mines, should keep us continually advised on all points of interest in these connections; reporting to us every important discovery, the result of development work, and what has been achieved at working mines.

Visitors to the Colonial and Indian Exhibition who take an interest in mining matters must be struck with surprise and greatly disappointed when they learn that the Dominion of Canada furnishes no official record of mining statistics, and up to date has neglected to publish any authentic information regarding the mineral resources of the country. With this fact before them, how can it be expected that capitalists will be induced to aid us in developing and extending our mining industries, the importance of which the Government has so utterly disregarded.

A desire for speculation and investment in distant and unknown countries has hitherto been a craze among English and European capitalists. Canada possesses some of the best mining fields in the world, and her mineral deposits are sufficiently rich, varied and extensive to invite investigation at least. If the minded men of England who are seeking investments in the mining fields of other countries are skeptical or incredulous as to the richness and vastness of our deposits, we most respectfully request that they examine carefully the display of Canadian minerals at the Colonial and Indian Exhibition and from it draw their own conclusions.

We learn that among other recent visitors to the Mineral Court at the Colonial and Indian Exhibition was Mr. Percy Gilchrist, the well-known English ironmaster and metallurgist, who inspected the exhibits in his capacity as one of the committee appointed by the Iron and Steel Institute to inquire into the iron and steel producing capabilities of the various Colonies represented at the Exhibition. Mr. Gilchrist acquired much valuable information regarding Canadian Iron Ores and was furnished with numerous samples of the ores and pig-irons. These he purposes having analyzed for publication in his committee's report to the Institute.

"A curious bit of experience," says the *American Manufacturer*, "has been had recently at one of the leading steel mills in the United States. A quantity of material for a bridge was rejected by the inspector of the buyers, much to the surprise of the producers. The manufacturers decided to make an independent investigation, which resulted in showing that the rejected material did come up to the specifications. Further research followed, and developed the fact that, for a given number of hours after the material had left the rolls, its physical qualities gradually changed, reaching a period of rest only after a certain time had elapsed. If these facts are borne out by the experience of others a good deal that is mysterious in steel may be explained."

Mr. L. Tietjens, of Stassfurt, Germany, has recently patented a very ingenious method of damming back the flow of water in shafts by the application of the well known fact that certain salts increase their volume very materially by the absorbing of water of crystallization in hardening. To accomplish this, he takes either calcined soda, anhydrous alum, kieserite, or oxychloride of magnesium, mixes them into a paste, and then immediately injects them through a suitably arranged pipe into the fissures through which the water flows. As this paste hardens, it swells enough to fill all the interstices of the rock and to render it thoroughly water-tight.

THE PHOSPHATE TRADE.

Little or no change has been reported in the condition of this industry during the past three months. The foreign market continues inactive and prices rule lower than we have known them within the past four years. Miners, however, have not been discouraged by the fall in values and have not allowed activity at the mines to relax, being confident of a rising market before the close of the shipping season. For this reason also they have been in no hurry to forward their output, as is shown by shipments to date compared with those of last season. While the year's production has not fallen off, the shipments up to and including August have aggregated but 11,256 tons crude, and 1,562 bags ground, as against 14,590 tons crude shipped to same date last year; whereas, the shipments for the month of August just past amounted to 4996 as against 3053 tons for the same month in 1885.

As our quotations show, in the subjoined report, prices have fallen as low as 11 pence for 80 per cent. with one-fifth of a penny rise; but this condition of things is not likely to last, as high grade phosphate is becoming scarce and *Canadian* must, therefore, command a higher price so soon as this fact is realized. There has been a shrinkage in values of all commodities, but apart from the effect of this, and the general agricultural depression, the price of phosphate has been further reduced by competition among the sellers of *Carolina* which is in such large supply that it regulates the market in a great measure. These people have been ruining each other and we have received information that they have become tired of the contest and are planning a combination to raise prices, so that an upward movement for all grades is anticipated for next season.

Indications of a firmer market are apparent already and better prices may be looked for this fall for *Canadian* though the improvement is not likely to occur in any marked degree.

The popularity of Canadian phosphate is now very general with manufacturers, and there is no longer any question as to a large future demand for it in Great Britain and on the Continent. A demand for the ground article is also expanding, and if this is furnished in satisfactory form its use will be speedily extended. The Northern United States must furnish a large market in the near future, and Canada, too, must awake to the necessity of using our mineral phosphate as a fertilizer.

An eminent authority in London, Eng., referring to the Canadian deposits, says:—"There is one thing to be relied on; there will be always a large and increasing demand for mineral phosphates. Nitrogen can be obtained from wood and a multitude of other substances, but the only largely available and cheap source of phosphoric acid is from these minerals."

The facts above enumerated go to show that there will be no falling off in the demand, but that it will increase in proportion to the increased production of our mines, and, referring to the supply of

Canadian phosphate, Dr. Selwyn, during his visit to the Colonial and Indian Exhibition, in his capacity as Director of the Geological Survey, made the following statement:—"I can see no limit to the depth of the phosphate deposits of Canada. Of course there is a limit to the depth at which profitable working can be carried on, but practically there is no limit to the supply; it extends over an enormous area horizontally, as well as to great depth, and it must take centuries to exhaust it."

Practically then, the demand for the product of Canadian phosphate mines is unlimited, and the mines of the Perth and Kingston districts, and of Ottawa county, are inexhaustible. The annual production is rapidly increasing, and phosphate mining gives bright promise of becoming one of the most important industries of the Dominion.

Phosphate Quotations.

Prices for mineral phosphate have not varied much since our last report, except when the price of Canadian dropped to 11d. for 80%, with one-fifth of a penny rise. It has since rallied, and now stands at 11½d for 80%, with a more hopeful outlook for a revival of the market later in the season. No marked improvement is anticipated this year, but a firmer feeling is apparent and better prices are expected all round next year, especially for the higher grades, which are becoming scarce. In the English and Continental markets Canadian phosphate has gained much favor of late, and will always be in demand.

Phosphate Shipments from Montreal to August 26th, 1886.

Total.....11256 tons crude, 1562 bags ground.

A new gold field in the northern part of Western Australia has been discovered, which is estimated to extend over an area of nearly 4,000 square miles. Already there is a rush of diggers toward the place.

PHOSPHATE MILLING.

Amongst recent additions to the mining industries of the Ottawa district may be mentioned those of the Du Lièvre Phosphate Mining and Milling Company. This company bids fair to do an extensive business, as its undertaking is a most timely one, and of such a nature as is likely to prove of practical economy to the producer as well as to the consumer.

Not long since a correspondent of the REVIEW had the privilege of going through the new mills and witnessing the "Blake" crusher and other machinery in operation, for which, and for the explanations given, we are under obligation to Mr. Geo. H. Bacon, the Managing-Director of the company.

After the phosphate has been broken into fragments of the size of a walnut, it is made to pass through a long inclined cylinder, heated to a high degree in order to rid the mineral of moisture, which feeds it into a crusher to be pulverized. It is then brought in small tin buckets on a belt, as is the case with flour in an ordinary grist mill, and gathered in bags for shipment. There are several grades of ground or pulverized phosphate, depending upon the pulverizer or crusher used. In one instance the ore when dried is made to fall into a revolving chamber, where, through friction and rapidity of motion, it becomes reduced to a minute or impalpable powder. This is the best and highest grade. Its fineness is exceedingly great, and it may be used as a fertilizer in its raw state to great advantage.

Many shipments of ground phosphate have already been made by the Du Lièvre Company, notably to St. Catharines, Ontario, to be used in grape culture, &c., and to the United States. It is not unlikely that agriculturists in the northern and western United States and the Province of Ontario will become large consumers of our ground phosphate in the near future, and a large demand may be looked for in Great Britain and Europe.

A number of buildings have been erected on the west side of the Rivière du Lièvre, in proximity to the crossing of the Canadian Pacific Railway, consisting of the cylinder and boiler-room, the mill proper and a store-room, all of which are admirably fitted up for the purposes for which they are required.

Under proper management this will no doubt prove a successful and profitable enterprise, and we hope its promoters will receive a large share of patronage from the agriculturists of the Dominion.

The annual production of gold in the world has been on the decrease for a number of years. California's production reached its height in 1853, and that of Australia in 1856.

NATIVE COPPER IN IRON PYRITES.—A curious mineral association is reported as occurring in the *Champion* copper mines in New Zealand. The copper ore occurs in the fissures of the alumina-magnesia silicate, known there as serpentine, and native copper is found filling all the fissures in the white iron pyrites, making it almost impossible to break such pieces with a hammer. These pyrites themselves contain only from 3 to 4 or 5 per cent. of copper. There are also good copper pyrites in the vein; but the native copper is rarely found in them, but is confined almost exclusively to the poor white pyrites.

MICA MINING IN CANADA

A GROWING INDUSTRY.

The British and Canadian Mica and Mining Company

OWNERS OF

THE BEST MINE IN AMERICA.

This industry has been engaged in in a desultory fashion more or less during the past ten years, and until within a recent date has been confined to deposits in Central Ontario. Throughout the Perth and Kingston districts, especially in the Townships of North Burgess and Longborough, deposits of amber mica of various shades occur, and from these there has been a limited annual production, which, for the most part, has been used to replace the better quality in stoves which have been for some time in use, or, in other words, for the purpose of repair. One deposit, however, in North Burgess, known as Pike Lake Mine, has yielded a very large quantity of excellent mica with so pale a tinge as to appear almost white when split to the required thickness for stove use. An almost unlimited supply can be obtained from

THE PIKE LAKE MINE,

and the product is far superior to any which has been extracted from the other deposits in the districts referred to. A fairly profitable trade was carried on by the owners of these mines until within the past two years, when the price of the higher grades of mica (*Muscovite*) were reduced on account of the discovery of extensive deposits in the United States and in other localities in Canada. Of these recent discoveries none have been recorded to compare with the deposit in the Township of Villeneuve, Ottawa County, which is now being worked by

THE BRITISH AND CANADIAN MICA AND MINING COMPANY.

This company own and operate what is known as the *Villeneuve Mine*, situated five miles east of the Rivière du Lièvre, and about twenty miles north of the village of Buckingham. The mine was acquired by its present owners in March last, previous to which it had been exploited only to a limited extent, but sufficiently to prove the existence of a vast body of feldspar and quartz intersected by micaceous veins carrying well formed crystals of mica in great quantity, capable of producing plates of various sizes from the ordinary dimensions required for stove purposes up to 10 x 12 inches.

THE QUALITY OF VILLENEUVE MICA

is not excelled in any part of the world; and this has been attested to by experts who saw the samples exhibited at the Antwerp Exhibition last year, and by those who have seen the samples now on exhibition in London at the C. & I. E.

In April last the British and Canadian Mica and Mining Company began active operations, and proceeded at once to develop their mine in order that they might be prepared to supply consumers with their requirements for the present season. No difficulty was experienced in convincing dealers, and others, of the superior quality of the mica, and as soon as they were satisfied of the capabilities of the mine, as regards quantity, the demand became so brisk as to tax the company's facilities for producing it to their utmost extent.

A mine cannot be developed in a few months, but under the superintendence of Mr. L. H. Shirley, C. E., the Managing Director, the mine is being put in shape to enable the company to employ a large force of miners. The micaceous leads are so extensive that the supply of mica is practically unlimited, and when more ground has been opened this mine will be capable of yielding all that will be required for consumption in Canada, as well as a large annual production for exportation.

Already many of the large stove manufacturers in Canada have obtained their season's supply from the Villeneuve mine, and a large quantity has been shipped to the United States where it competes with the North Carolina mica.

The B. & C. M. & M. Co. have organized with a view to carrying on a permanent industry in connection with their Villeneuve property, proof of which we have in the substantial character of the buildings which have been erected at the mine, the well constructed roadway thence, for a distance of five miles, to the river, and

THE CUTTING HOUSE AT BUCKINGHAM.

This latter feature is the most interesting addition to the company's property and is complete in all its appointments. No cutting-house in connection with any other mica enterprise in America can be compared to it. Each day's output is forwarded from the mine thither in crystal form and handed over to the sorters, splitters, cutters and packers who prepare it for market. To each man and woman employed in the cutting house is apportioned his or her special work, and everything in connection with the building has been so ingeniously arranged and thoroughly systematized that this branch of the business is conducted like clock-work. The difficulty at first experienced in obtaining skilled labour was overcome by importing

TRAINED HANDS FROM FRANKLYN, NORTH CAROLINA,

under whose instruction all the employees have become expert in the special work assigned them. Everything is conducted with a view to economy, and in this connection, it may be said, the company have very good prospects of establishing a profitable market for the feldspar, of which the gangue is, to a large extent, composed. Its superior quality makes it adaptable to the manufacture of porcelain, and its association with the mica renders it necessary to raise hundreds upon hundreds of tons in the ordinary course of mining. In addition to this, the distorted and fractured crystals, cuttings, and all waste mica is ground and sold to manufacturers of fire-proof paint, roofing cement and lubricants, and by utilizing these by-products the company will reduce the cost of producing the mica plates to a minimum.

The value of this property is no longer problematical; it has been thoroughly established, and of the mica, it may be said that its perfect transparency and its refractory nature, as well as the unusually large size of the plates obtainable, and the careful way in which it is cut, cleaned and otherwise prepared for market, has made a reputation for the product of the Villeneuve mine which must render it a source of large profit to its owners, of whom it is said, they possess THE BEST MICA MINE IN THE WORLD.

A New York scientist says that the earth's polar ice is penetrating the interior of the globe, like a wedge, and that as soon as it reaches the furnace there will be an explosion that will split the world into pieces too small for truck patches.

THE UPPER LIEVRE.

A Search for Gold and Silver now Going on in the Region.

It is only since the opening up and successful working of the phosphate industry that the attention of the outside world has been turned to the at one time avoided and rocky regions of the Lièvre Valley. Especially in the Upper Lièvre country is it beginning to dawn upon the few and far separated settlers that while nature has not been lavish in the bestowal of agricultural resources, yet she may have more than compensated for this by storing up mineral wealth in the vast masses of igneous rock that everywhere abound. With such a conviction Mr. William Riley Clement, of White Fish Lake, after a somewhat extended experience in the Huronian Gold and Silver mining regions, set to work with a will to search the rocks. It is quite probable that he will soon reap a tangible reward for his diligence and enterprise, as he has succeeded in discovering what seem to be very good specimens of both gold and silver quartz. These findings are located on White Fish Lake, in the townships of Bigelow and Bowman, and were last week inspected by Messrs. Edward Watts and Patrick Powers, of Buckingham, both of whom were very favourably impressed with the prospect, and who will likely be heard from in this connection shortly. Good specimens of gold and silver quartz have also recently been found on the properties of Messrs. William and Rodney Smith, at the upper end of White Fish Lake. A prominent phosphate miner and lumberman has already entered into negotiations with the latter gentlemen for the purchase of their claim.—*Asylmer Times*.

CORRESPONDENCE.

Editor Canadian Mining Review :

SIR,—Herewith find report of the manager of the Quesnelle Quartz Mining Company (limited). This mine is situated on Hixon Creek, Cariboo, British Columbia, about 43 miles north of Quesnelle Mouth. The property, as it now stands, consists of five locations of 1,500 feet each in length by 600 feet each in width, containing about 102 acres, to all of which the company have obtained a Crown grant, thereby giving them an absolute title, subject to taxation, as levied on all mineral property.

There are 300 inches (miners) of water recorded in favor of the Company. A five stamp mill complete, engine and boiler of about sixteen horse-power, are in place; also hoisting gear, wire-rope, necessary pumps, &c., for sinking 500 feet.

This mine was first located twenty years ago, but owing to excessive cost and lack of knowledge of such undertakings at that time, it was abandoned. Five years ago the present company was organized, and after expending \$32,000, found their manager was incompetent, in addition to which their funds were at a low ebb. The works were closed down, but not abandoned, as the company were satisfied that with sufficient means and a competent manager, success would crown their efforts.

The present manager, Mr. Koch, was engaged last October, and, in addition to the work as set forth in his report, put all the machinery and mill in place.

Yours truly,

JAMES REID,

(M.P. for Cariboo, and President of the Quesnelle Quartz Mining Co. (limited).

REPORT.

To the Trustees of the Quesnelle Quartz Mining Company, (Limited.)

QUESNELLE, BRITISH COLUMBIA.

Gentlemen,—Yours of a late date requesting me to make a full report on the Hixon Creek Quartz Mine is to hand, and I will endeavour to comply with your request in such a manner as to be well understood by each one of you, and will be as explicit and impartial as possible in reference to the mining property you control. I am pleased to state that while I was not favourably impressed with the general surface appearance of your ground, I did not allow my prejudiced opinion to become fatal to my judgment whilst making a study of the ground as work progressed. I am now pleased to inform you that you have discovered, and to a limited degree developed, a true contact fissure vein. The surface being covered with a large amount of gravel sedimentary wash and mining debris, made it difficult to trace the course of the vein. After getting the machinery in place and pumping out the deep shaft (100 feet) I found that nearly all the quartz which has been mined and milled was taken from the cross veins, properly termed feeders to the main or true fissure vein; all of these have a general N. E. and S. W. course and terminate at the true vein; but, being in vein porphyry, they are irregular in course and size, and if in their course towards the vein they chance to come in contact with a large vein they are led off in a hap-hazard way through the porphyry until they come in contact with the true vein where they always terminate. To the west and south-west of the fissure the country rock is talc slate which forms the foot wall of the vein and into which the feeders never penetrate, always merging into and ending at the point where they intersect the true vein. At many places in the cross veins the ore assays very high, varying from \$25.00 to \$150.00 per ton. Between the two shafts, a distance of 160 feet, there are no less than ten large and small feeders traversing the country and intersecting the porphyry until they come in contact with the true vein. Again, in the tunnel, which is on the same course as the two shafts, the inner end being 450 feet distant from the furthestmost shaft, quite a number of cross veins, one of them measuring four feet in thickness, have been exposed, all of which have a N. E. and S. W. course toward the true vein. Some of these cross veins prospect very rich in gold, thus showing 450 feet of vein ground prospected and thickly interspersed with strong veins, or feeders, containing gold. All ground lying N. E. of the vein, for a distance of 50 or may be 1,000 feet, is vein porphyry, composing the hanging-wall of the fissure, impregnated with gold, iron, copper and silver, independently of the large and small veins which serve as feeders to the main fissure vein.

The vein is what is termed a true fissure vein and also a contact vein, and in California, Montana and Idaho, mining men cannot be induced to invest in a silver or gold vein, unless it is a true fissure vein, whilst others seldom have unlimited confidence in a vein unless it is not only a true fissure but also a contact vein. When a pay chute of gold quartz has been discovered in a fissure or contact vein it is likely to continue for several hundred or a thousand feet along the vein and to an indefinite depth, giving perfect assurance of a valuable mine. I am pleased to inform you that the main vein of your property on Hixon Creek, so far as developed, proves to be a true fissure contact vein, between slate and vein porphyry walls.

I will now give you a description of your mine so far as developed. The extreme S. E. work on one of your claims is a shaft 150 feet deep on a vein of quartz which yielded well in free gold. At a depth of about 20 feet this vein dipped to the S. W. and away from the shaft. The shaft was continued vertically and at a dept of 100 feet a level was driven to the S. W. until the contact between the slate and porphyry was reached. Several veins which paid well were exposed by this work, but, not knowing that a vein existed at the contact, your manager very naturally mined and milled the ore from the veins in sight. I am informed that, subsequently, a misunderstanding arose between the manager and the company which led to the suspension of work.

As soon as I was entrusted with the management of your property I placed the machinery at the shaft which you had appeared to know most of (so far as you had been informed by the former manager and others), rather than at a shaft only 50 feet deep and which had been sunk twenty years or more ago. In the course of my investigation of the shaft I discovered the contact of the slate and porphyry, but no vein, and being totally ignorant of the character and formation of the country I proceeded to open up ground by drifting through the porphyry and cross-cutting the slate in search of a more permanent vein than any of those which had been met with. Meeting with no success, beyond cutting through many small veins (some of them rich) in the porphyry, I concluded that a true fissure vein existed near by which controlled the movements of such a network of small veins, and into which these small veins would eventually find their way and act as feeders to it. I then proceeded to examine the other shaft, 160 feet to the N. W., and at a depth of 50 feet I discovered a drift which had been driven for 88 feet in the direction of the other shaft in vein porphyry. This drift intersects ten quartz veins, the largest two of which have been driven on to the S. W. until they ran into what I have discovered to be the true fissure contact vein. From this vein the quartz of the neighboring country has its source, and the millions of dollars of gold taken from the placer diggings of Cariboo have their origin in this and other true fissure veins of the district.

The vein is contained between talc-slate and porphyry and into it the two cross veins, or feeders, have been deposited. Beyond the fissure vein, and in the slate, not a sign of quartz is to be seen, proving not only its true and permanent character, but also that all the cross veins in the 88 feet drift and those at the bottom of the shaft serve as feeders to it. The vein proper has a N.W. and S.E. course and dips 75° to the N.E. with the vein porphyry acting as a hanging-wall and the talc-slate as a foot-wall. The tunnel, at a distance of 75 feet from the last mentioned shaft, has been driven 200 feet into the mountain and, like the two shafts, exposes many seams of quartz in the vein porphyry all trending towards the contact and several of them have been followed for short distances in its direction.

After making a careful survey and study of the formation and character of the vein at and near the bottom of the 50 feet shaft, where the true vein had been exposed to view, I decided to sink a shaft near the entrance to the tunnel. At a depth of 16 feet I encountered the slate in which I proceeded to drift in the direction of where I considered the vein would be found encased between the slate and porphyry. Continuing for 16 feet I came upon the contact with the vein standing up at an angle of 75°

surrounded and covered by surface slide and debris. At this point the vein is wide, well formed and contains more or less quartz. Its present appearance leads me to the belief that it will develop into a splendid gold mine and will make larger and become more reliable as a regular producer, as it leads N.W. and into higher ground. Another shaft can be sunk some 300 or 400 feet to the N.W. which will open up a very large extent of the vein and eventually make a thoroughfare and serve to ventilate the mine. The shaft I am now sinking is 8'4"x3'8" (inside of timbers), double compartment, timbered and properly secured. I have good and substantial hoisting frame over it for steam or water power. I have remodeled the water power and am now utilizing it for hoisting purposes. The shaft is now down 20 feet on the vein and the vein matter becomes harder as we go deeper. Much quartz is coming in (quartz belonging to the vein), while we are never without the quartz that cuts in from the porphyry, thus showing that we are in the midst of mineral.

I am very confident of being able, at no distant period, to supplement the foregoing with a report of good milling quartz in abundance.

G. A. Koch, Manager.

CANADA'S MINERAL WEALTH

REPRESENTED AT THE
COLONIAL AND INDIAN EXHIBITION.

The Display Attracts much Attention and the Richness of our Ores Creates Surprise.

No event has occurred in recent years so likely to promote the interests of Canadian industries as the Colonial and Indian Exhibition now in progress in London, England. The display of the product of the mine, which so well represents the mineral wealth of the Dominion, has attracted the attention of mineralogists and capitalists of the old world who will doubtless institute further investigation and ultimately be induced to advance capital to aid in the development of our vast mineral deposits. Nature has provided us with all the natural elements of national wealth and prosperity, and the C. & I. E. may be the means of furnishing us with those artificial elements, capital and enterprise, which are so indispensable to the successful development of great mining industries. The *Canadian Gazette* has been nattering in commenting on the Canadian exhibits, of which it speaks in the most laudable terms, and of Canada's mineral display it says:—

THE PRECIOUS METALS.

Among the gold exhibits the obelisks form a leading feature. The British Columbian structure contains 252,000 cubic inches, and represents the amount of gold taken from auriferous deposits in the Province during the last twenty-five years, of a total value of \$49,342,900. The Nova Scotian obelisk represents a total of 395,180 oz. obtained in the Province up to date, of the value of about \$7,500,000. Many interesting specimens of alluvial gold from different parts of the Dominion are also shown in a case in the approach. Among them is one from the parish of St. George, Beauce County, Quebec, found in an old river 200 feet below the surface. The specimens from Granite Creek, Similkameen River, British Columbia,

are the largest from the Province, and from a new district that promises well. A handsome sample in quartz comes from the Albion gold mine of Montague, Nova Scotia. Exhibits of gold-bearing ore may also be seen from the Huronian mine, in the region of Port Arthur, of which so much has been heard of late years. Of silver the chief exhibits are made by Mr. T. A. Keefer, thanks to whose enterprise a most comprehensive and interesting mineral collection is shown from Port Arthur, in twelve handsome cabinets made of wood found in the same district. The silver from this region is, it will be noted, not so much native silver as blends with copper pyrites, &c. A large number of veins have been discovered in various parts of the district, from most of which specimens are shown; but little has been done in providing capital and enterprise to develop the industry. The Beaver mine has as yet been worked to the largest extent.

PHOSPHATE AND ASBESTOS.

There are, however, in the whole collection few exhibits of more practical interest to Englishmen at the present moment than those of phosphate of lime, or apatite, as it is at times called. The development of the trade in this mineral is most remarkable. In 1873 but 195 tons were obtained from the Ottawa mining district, where the chief bearing rocks are found; in 1883 the supply had reached 19,466 tons; and last year the total was 23,908, with every prospect of as great advance in future years. From the Emerald mine, Buckingham, Quebec, a crystal is shown some twenty inches in width, probably the largest individual apatite crystal yet found. In quality the mineral is one of the richest known, very similar to the phosphate of Norway, and yielding a high amount of phosphoric acid. For instance, the South Carolina phosphates give 40 to 50 per cent. of phosphate of lime, while in the Ottawa region a carefully conducted mine yields upwards of 80 per cent. It is now largely exported to Great Britain and Germany, and already practically holds the field, with the exception of the product of Norway, for the Spanish phosphate is of a different nature, with a different method of occurrence. Another most interesting exhibit is the case of the Anglo-Canadian Asbestos Company of Montreal, devoted to the mineral in its crude and manufactured state. First is the raw asbestos, then powdered for the manufacture of fire-proof paints, also woven into tape, wick and rope—in short, it can be made into almost everything into which cotton is manufactured. The fibre of the Anglo-Canadian Company's asbestos is comparatively short, but the exhibit of other firms, such as Messrs. Johnston & Sons, from the same district of the Eastern Townships, is larger and more similar to the Italian article with which Canadian asbestos has to compete in European markets. No general statistics are apparently available as to the extent of the output, for the industry is a new one; but the demand is such in Europe alone that few better investments could be found. Some of the chief mines are at present worked by Americans, and indeed throughout Canada it will be found that English money, which should perhaps be first, is often last in developing industries of a similarly profitable nature.

MINOR MINERAL EXHIBITS.

Mica and soapstone are also well represented among the exhibits. The latter is attracting much attention as a stone where great resistance to heat is acquired, such as in stoves. The material now in use in Great Britain comes chiefly from Germany, and from what practical

Englishmen who have examined the samples say, there is every reason to anticipate a good export trade in the Canadian article. The mineral is found in the same district as the asbestos. Graphite is another mineral possible of large development in Canada. The largest exhibit is that from the Buckingham (Quebec) plumbago mine, comprising disseminated ore, pure lump plumbago from as many as fifteen different veins, and various manufactures. Few people, for instance, would think of asking in English shops for Canadian lead pencils, and yet they may be seen to be at least as good as those in general use, and probably quite as cheap. Crucibles and such-like manufactures of no little variety are also made of this mineral. Of precious metals the Mineral Court can also show specimens of much excellence. The amethysts from Thunder Bay shown by the Canadian Executive Commissioner and by Mr. Keefer are remarkable for their size and beauty. Canadian freshwater pearls are well shown by Mr. G. Seifert, of Quebec, in a small case in the approach. These pearl mussels are found in most of the small streams of Quebec, and weigh from 3 to 70 grains.

It will thus be seen that the Canadian mineral exhibit is one of great interest and merit. It is also a very practical effort to encourage English capitalists to assist in opening up some of Canada's immense wealth. Some English money has in the past been embarked on mineral ventures, and many such have failed. The cause of this is obvious. In the first instance far too large a sum has often been given for the property—so much so as in many cases to make profitable working only possible in the remote possibility of the mine proving a true "bonanza." With, however, proper care and judgment in the purchase, and economical and experienced working, there is great field in many directions for the profitable employment of English money in the Canadian mining industry.

CANADIAN GEOLOGICAL EXHIBITS.

Probably no Canadian industry has suffered so much from over-speculation, and in many cases from gambling, than that of mining. In deed, among certain classes the industry has been regarded in no other light, until the impression has found wide acceptance, if not in Canada at least in Europe, that the honest investor had best keep himself free from attempts to derive from it any permanent and satisfactory source of revenue. The display at the Colonial Exhibition is eminently suited to dispel such an illusion, and it will do so by showing clearly enough that, while in mining, as in lumbering and farming, absence of practical knowledge and capital have in the past led to many unprofitable ventures, yet the native material, comprising 97,000 square miles of coal-bearing rocks, is such that mining may and will be made in Canada, as it is in the older countries of the globe, a steady and increasing source of wealth.

The mineral exhibits occupy a large space in the annexe to the approach to the western transept of the Central Gallery and in the approach itself. The collection numbers upwards of 725 specimens of ores and minerals and their products, and was for the most part gathered during the past year in all sections of Canada by the Dominion Geological Survey. It is under the charge of the Director of the Survey, Dr. Selwyn, assisted by Mr. F. D. Adams and Mr. C. Willimott.

THE COAL WEALTH OF CANADA.

Treating the exhibits in the natural order into which they seem to fall, one finds in the approach an immense block of bituminous coal

from the Wellington mine, Vancouver Island, representing the whole thickness of the seam. Another block is from the Nanaimo mine. These two are the most important mines of British Columbia. From the former, 220,000 tons were obtained last year, worth \$4 per ton at the wharf; while from the latter the output was 137,500 tons, and, considering the sparseness of the population, this is a fair development. There is also bituminous coal from Vancouver Island and from the Union mine, Comox; and anthracite from Queen Charlotte Islands, interesting as the only known deposit of its kind on the Pacific coast. The extent of coal in British Columbia is but partially ascertained, and yet enough is known to show that the supply is practically inexhaustible. Its market is at present in Victoria, San Francisco, Honolulu, and Alaska, but it is greatly restricted for want of enterprise and transport facilities. In this respect much is hoped for from the completion of the Canadian Pacific Railway in opening up profitable markets, not only in the prairie cities of the Canadian North-West, but also in China and Japan, where the supply is now largely met from Australasia. As one passes from the Pacific coast eastward the deposits tend to a lignitic nature. From Banff, on the line of the Canadian Pacific Railway, in the mountains, a semi-anthracite is obtained, as may be seen by the specimen shown. The Banff mine, which is known to comprise two seams of about 4 feet in thickness, has but recently been discovered. In quality the fuel compares with some of the best anthracite in Pennsylvania, and is about to be mined in such a way as to ensure its extensive use. Further west on the line of the great coal-bearing rocks of the North-West comes the Lethbridge mine. This is now being actively worked by the North-West Coal and Navigation Company in connection with the operation of the railway from Dunmore, on the main route of the Canadian Pacific Railway to Lethbridge. The specimen shown from the Galt mine, as it is popularly called, is from a seam 5 feet 4 inches in thickness, situated so near the surface as to obviate the necessity of any shaft, and make working a simple and comparatively inexpensive process. The extent of this coal region is enormous. At Lethbridge alone the quantity underlying one square mile is estimated by Dr. Dawson at five million tons. And it must be clearly borne in mind that the Geological Survey has only as yet examined the southern regions of the plains, which form one vast coal bed tending from bituminous to lignite as one proceeds from west to east. The coal shown by Messrs. Pocock, Freath and Pocock, from the Souris Valley, Southern Manitoba, is thus a lignite with about 20 per cent. of water, as against about 10 per cent. in the Lethbridge coal. And yet the Souris coal is of the utmost value to settlers, and also in view of manufactures, for the fuel used by the Germans for like purposes is to a large extent much inferior.

From Ontario and Quebec no specimens are forthcoming, because no coal is found in those provinces. New Brunswick sends but one exhibit from Grand Lake. This coal lies near the surface, and the seams are so thin that, seeing the close proximity of the vast coal areas of Nova Scotia, it is used only for local purposes. The extent of the coal fields of Nova Scotia may be gathered from the fact that last year the total output was 1,352,000 tons, and the local Government have done well in seeing the province so well represented as it is. In all thirteen mines contribute—the Sydney, Bridgeport, Reserve, Glace Bay, Gowrie, Old Bridgeport, Springhill, and Albion, and the mines of

the Low Point Barasois and Lingan Mining Company, the Joggins Coal Mining Company, the Vale Coal Company, the Acadia Coal Company, and the Intercolonial Coal Mining Company. The coal is of the true bituminous class and of immense extent, at present worked to supply the demand of the Maritime Provinces and as far west as Ottawa, beyond which it is not at present profitable to send it.

IRON AND COPPER EXHIBITS.

The exhibits of iron comprise every kind of ore from all parts of the Dominion, Nova Scotia prominently, as well as New Brunswick, and parts of Quebec, Ontario, and British Columbia. From the largest iron works in the Dominion, Londonderry iron mines, of Colchester, Nova Scotia, a good exhibit of ores and products is made. In quality Canadian, and especially Nova Scotian, iron must be considered a great deal better than the general run of English iron. It is, in fact, very pure and rich; the magnetites compare somewhat with those from which the celebrated Swedish iron is made. And an idea may be gained of the immense market available in the Dominion itself for this abundant metal from the fact that in 1884 the iron and steel imported into this country in various forms reached a value of \$14,790,727, and the total of imported iron and steel during the seventeen years since Confederation amounts to a value of no less than \$230,741,434, a demand which the resources of Canada are well able, with proper development, to meet. Sulphites of copper come from Quebec, British Columbia, and Ontario, the latter including two exhibits of native copper from the Lake Superior district, which should, now that it is opened up by the Canadian Pacific Railway, attract capitalists to work what is declared to be one of the most extensive copper deposits in the world. Of antimony some fine specimens are shown from Rawdon, in Nova Scotia, as well as from Prince William, New Brunswick, from which much is hoped.

There can be no doubt but that the mineral exhibits have aroused considerable enquiry among visitors generally to the Canadian section. The specimens of iron ores, manganese ores, asbestos, soap-stone, graphites, and granites have attracted particular attention, and there have arisen several offers to buy largely if satisfactory quotations can be obtained. In all such cases inquirers are put into direct communication with the Canadian producers. One gentleman who has carefully examined the iron ores recently, is about to leave for British Columbia to erect, at considerable cost, works for smelting purposes. Mr. Sugg, of the Vincent Works, Westminster, a member of the well-known firm of gas engineers, has also recently been placed in communication with the miners of soap-stone in the Eastern Townships of Canada. Large quantities of this material are at present imported by Messrs. Sugg from Germany for use in their works, and it is hoped that an article of as good, if not better, quality may be obtained from Canada at favourable prices. Other inquiries have related to Canadian ochres, and many samples of this mineral have been furnished for experimental purposes and for report to the Geological Survey.

While workmen were engaged in blasting rock recently at the limestone quarry at McAfee, in Orange County, New York, a seam in the rocks was opened, in which was found a number of bones among others some that are alleged to be those of a man. There are pieces of the vertebrae of an ox, and a piece from some huge beast's jaw containing a tusk.

Progress in the Development of Canada's Mining Industries

DEPICTED BY

ALFRED R. C. SELWYN, F.R.S., F.G.S., C.M.G.

Director of the Geological Survey of Canada.

The collection of the economic minerals of Canada forms one of the most interesting and important exhibits at the Colonial and Indian Exhibition, and is strong evidence of the progress in the development of the country's mineral resources since the displays made at the Philadelphia Exhibition in 1876 and at the Paris Exhibition in 1878, in both of which the Director of the Survey took a prominent part. In comparing the collection now on exhibition with those displayed in Philadelphia and Paris, Dr. Selwyn, speaking on the subject, is reported to have said:

"The exhibits are much more numerous, to begin with. We have here upwards of 725 specimens of ores and minerals and their products, whereas at Philadelphia we had but 487. Then our space is double that at Paris, and larger than at Philadelphia. The exhibits themselves are, I consider, finer, too, and of a more practical nature. It is also a great help to have the exhibits concentrated in one Mineral Court as we have here, instead of separated in the general display as at Philadelphia. Then, again, we had, in 1878, practically none of the fine asbestos and much less of the phosphate exhibits than we now show, for the important industries in these minerals have greatly increased."

He says, in referring to the

ASBESTOS AND PHOSPHATE DEVELOPMENTS,

"The market is unlimited: it is merely a question of capital to open up and develop mines. The workings are confined to one district—the eastern townships—where asbestos and soapstone lie very much together. Of course it is found elsewhere, but, so far as known, these are the only deposits of mercantile importance. As to quality, I am informed that the Canadian asbestos is quite equal to that produced anywhere, though not quite so long in fibre; but the fineness of the fibre and its quality are said to be quite as good for all practical purposes. It is now manufactured in Canada, and owners of mines would do well to remember that in exporting the raw material they are really exporting a good deal of refuse and refuse, too, that has to pay freight. Manufacture the asbestos before shipment, in accordance with the requirements of European markets, and the advantage will be with Canada all round. Of course capital is wanted for machinery and the facilities for manufacturing; this is the great difficulty, for exporting the raw material means small outlay and quick returns, which is a consideration to many owners. But, if taken up by men of capital in a reasonable way, and properly managed, the manufacture should offer a good opening for investment and be conducted with complete success. The trouble is, that the moment any English or American capitalists try to buy mining property in Canada, the owners say to themselves, 'Ah! there must be something exceptionally valuable here,' and they cannot open their mouths wide enough. The consequence is, as many instances have proved, the capitalists will not look at the property, knowing full well that the price is unreasonable; or, if they purchase, they often find it impossible, unless it prove a real 'bonanza,' to work it at a profit, and at last give up the undertaking in despair,

to the disparagement of the property and the industry. The most owners of Canadian mining property are not willing to make what seem to me reasonable and fair arrangements, such as royalty on the output, or to make the purchase conditional upon the result of the workings coming up to expectation.

"When I speak of the asbestos workings being confined to one district, it is a Canadian, not an English district, to which I refer. An English district is at most a small affair, but a Canadian district may be pretty well as large as half of England. The asbestos district, for instance, in the Eastern Townships is about 200 miles in length, and, I suppose, some six to eight miles in width. It is, therefore, a vast area.

"With regard to the phosphate deposits in Canada, the way they are being developed is shown by the growth of exports. I can see no limit to the depth of the deposits. Of course there is a limit to the depth at which profitable workings can be carried on, but practically there is no limit to the supply, for it extends over an enormous area horizontally as well as in depth, and must take centuries to exhaust."

PROGRESS IN COAL DISCOVERIES.

"The discoveries which have been made in coal during the last decade are entirely confined to the North-west and Rocky Mountains. There is no doubt that the North-west deposits are all that could be desired in every possible way. The Souris coal is a lignite; but the coal from the North-west Territory is found on the upper branches of the two Saskatchewan Rivers, away to the foot of the mountains, between Medicine Hat and Calgary, and even west." The question of freight is an important one and in this connection I understand the Canadian Pacific Railway is carrying the North-west coal at a cent a ton per mile, and the result of the opening of the mines has already been to bring the price of coal in Winnipeg from \$18 to \$7½, and proportionately cheaper as one goes west. The people in Manitoba now use about as much of North-west coal as they do of that from Ohio and Pennsylvania. Some say the American coal is slightly better, but the Canadian article should certainly supersede it in the towns of Manitoba. Government can easily effect such a change, and a little patriotism on the part of residents would also do it. This is a patriotism that pays and benefits the whole country—at least, it must seem so to those who can look beyond their own noses. As to quantity, there is certainly enough coal in the North-west to supply the country for centuries; of that there is not the slightest question. The Canadian Pacific Railway Company is now itself using the Saskatchewan coal in the place of the American, which comes in by way of the lakes to Port Arthur. As to the Bauff semi-anthracite deposit, of which so much has been heard, we hardly know the quantity as yet, and are not quite certain whether the deposits represent several seams or only one. It may possibly be that one single seam is folded, so that the two or three deposits represent several seams or only one. It may possibly be that one single seam is folded, so that the two or three deposits found at different spots are but parts of the one folded seam, and not individual seams of themselves. This question of course largely affects the quantity.

DISCOVERIES OF OTHER MINERALS

have not, for the most part, been very extensive. One very fine deposit of antimony was found at Rawdon, in Nova Scotia, in 1883, and also some manganese at Walton and Cape Breton in the same Province, where mines were opened in

1880. In the Port Arthur district, however, very considerable discoveries of silver ore have been made, and many of them promise to be very important, especially in the Rabbit Mountain district, about 28 miles west of Port Arthur, near White Fish River. Much has been said of this district but the actual results of mining have been small so far, accounted for by the bad condition of the roads which makes it difficult to get to the mines at present. It is a curious fact that a similar mining excitement arose fourteen years ago much nearer Port Arthur. A great number of silver mines were reported; splendid specimens were taken out of native silver and sulphuret of silver. Capitalists spent large sums of money, but the ventures were not successful. And yet these veins look just as promising as any I ever saw in my experience; but I cannot explain what seems hitherto to have been the unsatisfactory result in the older mines, such as Pie Island, Thunder Bay Mine, and others."

For the Geological Survey to undertake exhaustive examinations of the veins, to ascertain their exact extent, and thus enable capitalists to judge, would involve a great outlay, and difficulties would arise between the various owners; and then, if you ascertained a fact concerning one mine, it would prove nothing as to another. The matter is therefore, we think, better left to private enterprise.

"The only discoveries in the Rocky Mountains are on the west side, in British Columbia. Granite Creek, for one, has a very rich alluvial gold field; and doubtless many other creeks in the region from immediately west of the summit of the Rockies to Kamloops; but here, as everywhere else in Canada, they are waiting for capital."

AMERICAN VERSUS ENGLISH ENTERPRISE.

"If I remember rightly, the British Columbia Government have sold to Americans the whole of the coal lands along the eastern coast of Vancouver Island around Nanaimo. It is here that the men-of-war coal. And through the whole country mining and other industries are often largely, or entirely, worked by American capital. This is so, for instance, with one of the greatest lumber manufactories in Canada—that at Hull, Ottawa—which is, to some extent a slight upon English enterprise. But American capital is more plentiful than Canadian, while distance and ignorance of the country operate against the introduction of English capital. It is to be hoped, however, that much of this want of knowledge of the undeveloped resources of Canada, and the opportunities they offer for profitable investment, will be removed by means of the present Exhibition."

DIAMONDS IN NEW SOUTH WALES.—Diamond mining in New South Wales is likely to become of much importance. Upwards of 12,000 diamonds are reported to have been found up to the present time. They have been chiefly obtained from the Tertiary gravels and in the more recent drifts, in the Bingera, Inverell and Cudgegong districts; and a few have also been found in the Mittagong, Wellington and Uralla districts.

The production of chemical manure from the slag of Thomas-Gilchrist steel works promises to be successful in Belgium. Works have been started near Liège, which use all the basic slag from the Angleur Steel Works. Hitherto all that has been done is to pulverise the slag, and after roasting, the ground slag is sold to works where the natural phosphates of Hainault are dealt with, no difficulty being experienced in finding a market for it.

MINING NOTES.

NOVA SCOTIA.

On the 20th ult. the property belonging to the Blockhouse Mining Company, Cow Bay, Cape Breton, was put up at auction by order of the Commissioner of Mines, and sold for \$7,000.

The order, which was for unpaid royalties amounting to some \$12,706.35, dated as far back as June, 1885.

It is rumoured that the Government purpose taking up the rails and machinery with a view to abandoning the mine. If this is so, and the mine is allowed to fill up, many hundred thousand tons of coal can never be reclaimed.

Recent reports show that the works of the New Albion Gold Mining Company of Nova Scotia are at present at a standstill, gold in the worked leads having given out. Strong hopes are entertained that capital may be raised to develop other good leads on the property, but a report that an effort in this direction had proved successful lacks confirmation. It is unfortunate that the first Nova Scotia gold mine to receive English capital should have proved so far unsuccessful. Great results were expected from it, and these expectations were fully justified by the outlook when the property was sold. In July the stock was quoted in London at from \$4.50 to \$4.75, but according to advices during the latter end of August it sold at from \$1.25 to \$1.87½. Had the venture turned out well a great stimulus would have been given to English capitalists to invest in the mines of this province.

PORT ARTHUR.

The *Miner* has changed hands, and is now published by Mr. I. Dickinson.

Mr. Harvey, of Toronto, has given encouraging tidings regarding the mining property near Mackenzie Station on the C. P. R. east of Port Arthur. The vein recently discovered is said to be four feet wide at the surface, carrying galena and zinc blende, the same as 3A mine. It is also stated that a syndicate of English and Hamilton capitalists will work the property.

The works at the *Porcupine* mine now consist of a shaft on the northeast side, which is down about 60 feet, and on the southwest side the vein is stripped from the top to the bottom of the hill for 100 feet with four drifts into it, and the ground stopeled out between the centre drifts, thus exposing a large body of ore to view. Recent specimens brought in show pink and green quartz and fluor spar, full of heavy black silver—argentine. The *Miner* says it has long been the opinion of mining experts that the cross vein at the Beaver, which has proved so rich, the *Silver Creek* vein and the *Porcupine*, are all one, and the finding of the rich pink and green fluor spar seems to set the matter at rest.

During their recent visit to Port Arthur Sir John and Lady Macdonald and party visited the office of Mr. T. A. Keefer, and at the request of the Reception Committee inspected a very fine collection of specimens of the mineral wealth of the district.

The arrangement of the minerals was complete. On the first table in one row were arranged rich specimens of ore, lead, zinc, copper and gold and silver-bearing ores. In another row other economic minerals were shown, viz, free stone, asbestos, mica, roofing slate, marble, serpentine, Neepigon sandstone, and baryta; and in other places solid nuggets of native and black silver, and nuggets of gold in the rock; all from the district of Thunder Bay. This table had a card on it which reads as follows: "Table exhibiting some of the minerals found on the North Shore of Lake Superior, near Port Arthur."

In the centre of the next table there was written on a large card the following: "The working ores of the working mines near Port Arthur," underneath which was written the following: "To work with assured success and to increase the output of these mines a railway is essential. We need increased or special Government aid." On this table were exhibited the working ores of the following mines: The *Huronian* gold and silver mine, the *Rabbit Mountain* silver mine, the *Porcupine* silver mine, the *Beaver* mine, the *Jarvis Island* silver mine, the *Silver Mountain* East End mine, the *Silver Mountain* West End mine, the *Crown Point* mine, *McKellars Island* baryta mine, the *Chicago & Verte Island* sandstone quarries, *Silver Falls* silver mine. On this table were also shown the *Huronian* mine mill concentrates and a brick of silver from *Rabbit Mountain* mine. On a third table there was written on a large card placed in the centre of it the following: "Surface ores of proposed mines near Port Arthur," underneath which was written, "To successfully develop these prospects a railway is essential. We need increased or special Government aid." Around this table were surface specimens from the following prospects: the *Highland* gold and silver, the *Neebish* gold and silver, the *Kam Kam* gold, the *Tip Tap* gold, silver and copper, the *Big Bear* silver, the *Little Pig* silver, the *Indian* silver, the *Palasides* silver, *Slate River* silver, the *Parnseau* silver, *Rabbit Mountain, Jr.*, silver, *Corbett* and *Crawford's* silver, *Melottes* Black Bay argentiferous galena, and the *Zenith* zinc mine.

On another side of the office were shown varieties of ores in large masses and quantities, and the gold-bearing and silver-bearing slates of the district, together with a very fine collection of photographs of all the working mines, taken by Mr. Barrie.

There were also on exhibition *Huronian* mine mill concentrates in bags, also trees cut down by beavers from the *Beaver* silver mine, and a number of interesting geological curiosities.

Sir John expressed his great surprise at the variety and richness of the minerals, and each of the party carried away some fine specimens as mementos of their visit.

Notes on the Progress of Mining in Europe.

By E. J. BALL, PH. D.,

(Assistant in Metallurgy at the Normal School of Science and Royal School of Mines, London.)

Written specially for the *Canadian Mining Review*.

After an enquiry which has lasted seven years, the Report of the Royal Commission on Accidents in Mines was issued on April 10th. It is of considerable length and gives the results of a large number of experiments made to determine the best methods and appliances to be adopted in order to obtain increased safety from accidents in mines. It is stated in the report that with regard to the firing of shots, electrical exploding appliances present import-

ant advantages over their competitors, and it is added that the experiments instituted to show the percentage of fire-damp that might be present in the air without rendering it explosive, showed that 4 per cent. and upwards might lead to dangerous explosions, while if coal dust be simultaneously present the danger is still further increased. The commissioners recommend the use of Livings' Fire-damp Indicator, and they advise: 1st. That all work involving blasting in mines should be entrusted only to experienced workmen. 2nd. That in order to lessen the risk from blown-out shots, particular care should be taken that each shot should be assisted by under-cutting and nicking or shearing whenever it is practicable. 3rd. That the tamping, stemming, or ramming should consist of very damp or non-inflammable material. 4th. That, where strong tamping is needed, the compression of air at the bottom of the hole should be avoided by pushing in the first part of the tamping in small portions. 5th. That, where safety lamps are used, and powder is employed, the shots should be fired only by specially appointed shot-men, who, before firing the shots, shall satisfy themselves that the foregoing instructions are observed, and shall also satisfy themselves by carefully examining all accessible contiguous places within a radius of twenty yards of the shot to be fired, that fire-damp does not exist to a dangerous extent. The commissioners further add: "That it is most important that all mines should be carefully examined by means of indicators capable of detecting as small a proportion as 1 per cent. of gas; such examinations to be made before the announcement of each day-shift, and, in case of an interval, also before the succeeding shift, and that in all dry mines where the air may be laden with coal dust, and where fire-damp is either known to be given off from the strata, or may from experience be reasonably expected to exist. The Secretary of State may require safety lamps to be used, unless the owners and workmen of such mines prove, to the satisfaction of a Court of Arbitration to be appointed by the respective parties, that less liability to accident generally will be involved by the working of the mine with open lights than by the use of safety lamps. It should be a special instruction to such Court that the circumstances of each mine be taken into consideration."

In drawing attention to the experiments which have from time to time been made with a view to reduce to a minimum the inflammable action of a shot, H. Stapenhorst remarks that the results attained have been more satisfactory when dynamite was the explosive agent than when powder was employed.

As a complement to the discussion which has been carried on at such a length of late as to the action of coal dust in tending to produce, or in intensifying colliery explosions, the Austrian Government has offered a prize of 1,000 ducats for a process for getting coal which shall be free from all danger of explosions, and which must be neither costly nor troublesome to employ. The process may either do away with shot firing altogether, or it must be of such a nature as to prevent all danger from shot firing in dusty or fiery mines. Existing methods may compete, and all projects must be forwarded to the Berg-hauptmannschaft in Vienna before the end of the present year. Amongst the methods which have of late been proposed for the purpose is one described by Dr. Kossmann of Breslau, in *Oesterreichische Zeitschrift für Berg und Hüttenwesen*. He proposes to replace the ordinary dynamite or gunpowder cartridge by one in which the force is exerted by the rapid evolu-

tion of hydrogen due to the action of sulphuric acid on zinc dust. The case of the cartridge is divided into two chambers, the inner of which is filled with the zinc powder and the outer one with the sulphuric acid, the shot being fired by a blow on a pin forcing out a plug, and so opening a passage between the two chambers. The process is stated to be inexpensive.

In the same Journal it is stated that comparative experiments with compressed and with ordinary powder, recently officially carried out at Wieliczka, ended in favor of the compressed powder.

With regard to the various new forms of explosives, hellhoffite, mention of which was made on a former occasion, is stated to consist of one part of dinitrobenzole and 1.5 part nitric acid, or of one part of nitrobenzole and 2.5 parts of nitric acid. It is a dark red to brown colored liquid, and was originally used in thick glass or paper cartridges, but was afterwards employed after absorption by kieselguhr, and in this state it possesses considerable advantages over kieselguhr dynamite, both as regards lessened danger in the firing of gas or dust in collieries, and in producing a greater proportion of large coal; further, it is not so liable to sweat as the dynamite is, and even if the oil does become free, there is not much danger, as it cannot be exploded by concussion. The gasses also, which are produced on explosion are less noxious than those produced by dynamite. Hellhoffite, however, is liable to become decomposed after the lapse of a comparatively brief interval of time, and its manufacture has consequently been abandoned, another explosive—carbonite—being introduced in its stead. This material, while not being subject to decomposition, possesses all the relative advantages of hellhoffite, like which it also consists in part of nitrobenzole. It is also cheaper than all those other explosives, which, as is stated to be the case with carbonite, do not cause explosions in the presence of ten per cent. of fire-damp.

The experiments of A. Kás on the tensile strength of wire drawing-ropes were divided into three classes: 1, new ropes; 2, ropes already used but free from broken strands; 3, old ropes with some strands broken; this third class being again subdivided in connection with the position of the broken strands. A large number of experiments were made with several varieties of ropes and the results are given in tabular form. The author remarks that his experiments show that the tensile strength of the wire used in the manufacture of wire rope, far from being diminished, as has been supposed, by the twisting together of the wires, is, in reality, somewhat increased by that operation.

In a paper recently read before the Mining Institute of Scotland, Mr. A. Hill describes the Rio Tinto mine and discusses generally the mining industry of the province of Huelva, in the south of Spain. That portion of the province through which the mineral zone of the Sierra Morena passes is about 100 miles long and 40 miles in breadth, and it consists principally of Palaeozoic schists associated with feldspathic quartz, porphyry, and granite. Ores of copper, lead, zinc, and manganese, are found in considerable quantities. There are large masses of cupriferous iron pyrites and the more important ones, at Rio Tinto and elsewhere, are all worked by open-cast, although in several of the mines ordinary pillar and stall work is also carried on in those portions of the mass where the overburden was too deep to be cheaply removed. The deposits at Rio Tinto are fully described, as are also the methods of mining

adopted, and the metallurgical treatment of the ore. This last is very simple as it chiefly consists in heap-roasting and then washing out the copper sulphate, the copper being thrown down by iron.

In another letter read before the same Institute Mr. J. S. Dixon gives the results of a large number of experiments he has made at the Bute Colliery on the subject of the amount and mode of occurrence of subsidence and draw from working the coal. The examination related to the working of the Ell coal, which the author states was worked stoop and room up until the middle of 1881, when stooping was begun, but it was some time before it reached the line along which the section was taken. The excavation, which is complete, averages 5 ft. 6 in. in height and the superincumbent strata are allowed to fall and to fill up the space thus made. The experiments showed that the subsidence attained its maximum towards the centre of the excavated space, and that it gradually diminished in either direction. The wave of maximum subsidence regularly followed the working face and at an average distance behind it of 186 ft., this being equivalent to 1 ft. horizontal for every $3\frac{1}{2}$ ft. perpendicular. The country rock is generally of a firm nature, and the surface chiefly boulder clay. In describing, before the Manchester Geological Society, the section of a shaft sunk through the middle coal measures at Bardsley Colliery, Ashton-Under-Tyne, Mr. G. Wild mentions an interesting discovery of calamites, at a depth of 640 yards from the surface, the shoots of many of which were still attached to what, the author considers, were undoubtedly subterranean rhizomes.

A. Iwan describes in the *Oesterreichische Zeitschrift für Berg und Hüttenwesen* the Val de Travers Asphalt mine, Switzerland. The deposit occurs in the Jura formation between limestone and marl; it has a length of about 10 kilometres and a breadth of 2.5 kilometres. The annual production is about 60,000 tons. The bed has an East-West strike and dips to the South at an angle of from 1° to 3° ; it is 3 to 7 metres thick and is worked by ordinary post and stall, the pillars being left 4 metres thick.

F. Hartnigg describes in the same Journal the mining industries of the Upper Feistritz Valley, Styria, and of the neighboring districts. The chief rocks are gneiss and micaceous schist, and in these are found coal and ores of iron, lead, zinc and other metals. Limestone also occurs.

The Mining and Metallurgical Industries of Hungary have, of late, been attracting considerable attention both in Britain and on the Continent of Europe, and in a paper recently read before the Society of Arts, London, Mr. B. H. Brough gives a great deal of statistical information concerning these industries which he gathered during a visit to the Buda-Pesth Exhibition and to the mining districts of Hungary. He states that all mineral deposits of technical value are the property of the Crown, and that prospecting can only be undertaken with the permission of the Government mining authorities; a number of the more valuable mines are worked by the State. Mr. Brough describes the different deposits both geologically and historically, and remarking on the gold and silver mines of Schemnitz, he states that in 1690 they produced as much as 17,000 oz. of gold. The lodes occurring in the Schemnitz district proper are in biotite-trachyte. They course in a north-east, south-west direction parallel to one another and dip 45° to 80° towards east. They are filled with decomposed trachyte, quartz, or calc spar, containing auriferous silver

and lead ores, iron and copper sulphides and zinc blende. The dressing works at Schemnitz were constructed by Rittinger, and the most recent innovation is a second stamping of the ore; all that does not pass through a one-fifth inch mesh being automatically treated again. The Salzburg, or Lower Hungarian percussive table is found to be better than the Rittinger continuous percussive table, and although there are at the works three American iron stamps weighing 900 lbs. each, which do as much work as twelve continuous wooden ones, still these latter are on the whole considered more satisfactory. A great deal of statistical information relating to these mines is given by Mr. Brough. This is also the case in connection with the other mining districts of Hungary, and with regard to Transylvania he remarks that the oldest rock of this mining division is crystalline schist, above which is deposited mesozoic limestone and tertiary sandstone, through which burst various eruptive rocks which are traversed by gold veins, the gold being either free or associated with tellurium and sulphur. The largest quantity of gold is found where the rock is of average grain, and where the vertical main lodes intersect the veins with slight dip.

The tellurides from Nagyág are treated by boiling them with sulphuric acid pouring into water, allowing this solution to become clear and then precipitating the silver with hydrochloric acid, and, from the residual solution, the tellurium by zinc. In Transylvania stamps weighing 100 lbs. to 140 lbs. are used in the crushing of silver ores. The heads of stamps are of hard quartz blocks, and it is stated that the quartz answers tolerably well. The metallurgical industry of Hungary is also treated in the paper at some length.

Mr. P. L. Litchauer in an article in the *Berg und Hüttenmännische Zeitung* discusses various questions relating to the mining of the various Hungarian deposits of coal and of lignite. Coal, he says, occurs in Hungary in the carboniferous and Lias beds, lignite being found in the cretaceous and Tertiary rocks. The first colliery in Hungary was opened up in the year 1750, and the author describes at some length both the history of coal mining in Hungary and the laws connected with the subjects which have been, or are now in vogue there.

A translation from the Russian appears in the same Journal of a paper by N. Jossa, of St. Petersburg, on the reasons for the decline of mining and metallurgical industries in the Altaï Mountain District. He describes in detail the different deposit of ore and of coal, and gives statistical information relating to the production of gold, silver, copper, iron and lead during the years 1855-1884.

In the *Revista Minera or Metalurgica* appears a description by A. G. Espin of the mining industry of Portugal, and he describes the deposit of poor copper pyrites occurring at the Santo Domingo mine. This mine is situated at a distance of 14 kilometres from the Guadiana and about 50 from the sea. The ore deposit is of somewhat curious shape, and at its widest part has a width of about 60 metres, and a length of 600 metres. The ore averages about 2.75 per cent. of copper, though the percentage of this metal occasionally reaches 12. The present state and future prospects of the mining industry of Spain is discussed in the same paper by I. B. Vicens.

A series of articles on the mechanical principles of the modern stamp mill, by H. Louis has appeared in the *Mining Journal* and the subject is dealt with at considerable length.

BOOK NOTICES.

An English authority just to hand gives the following review of Mr. Griffith's 1886 edition of "The Iron and Steel Brand Book." "It is a valuable rather than interesting compilation. Nobody will think of turning over the pages of the book in search of amusement for an idle hour, and yet the work contains a vast amount of technical information for business men, handily arranged, and set forth in a manner that betrays no motive save a desire to produce a work of ready reference. Statistics of the output of iron and steel are excluded from Mr. Griffith's scheme, which aims at showing the kind and not the quantity, of the manufacture of iron now existent in Great Britain. A list is given of all the iron smelting works in England and Scotland whose iron is in the market. These amount to one hundred and sixty, and they contain seven hundred and seventy-one furnaces, of which one hundred and sixty have been standing idle since December, 1885. Charcoal iron is now produced by but one firm—located at Ulverston; and anthracite iron, since the stoppage of the Yniscedwyn Works, is represented only by the Ystalyfera Company of Swansea, which, however, also closed in December, 1885. Of cold blast iron there are now but twelve makers left, four in West Yorkshire, four in South Staffordshire, two in Shropshire, and one each in South Wales and North Lancashire. The hematite trade is represented by thirty-four firms, only ten of which combine the manufacture with that of other kinds of iron. Two hundred and twenty firms are included in the directory of mills and forges, sixty-five in that of steel converters, and thirty-three in that of steel rolling mills. For the record of brands, Mr. Griffith claims that though it does not set forth every description of iron, the headings are so comprehensive as to indicate the works likely to roll any section of iron that may be required. This of course, is a matter to be tested in practice, but of the general clearness of the arrangement and apparent completeness of the book there can be no doubt."

MINING REGULATIONS

To Govern the Disposal of

Mineral Lands other than Coal Lands.

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labour during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES, AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, &c., &c.

THE SCHEDULE OF MINING REGULATIONS

Contain the *forms* to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

At this quarry there is an inexhaustible supply of most beautiful white marble. Samples to be seen and information obtained at the office of the MINING REVIEW.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1ST of JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with,—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein,—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section,—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers", is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,

Commissioner.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office until noon on Monday, the 1st day of November next, for four timber berths of ten square miles each, more or less, numbered respectively 4, 5, 8 and 9, situated on Kicking Horse River, and Otter Tail Creek, a tributary of the Kicking Horse River, near Field and Otter Tail Stations, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position, approximately, of these berths, together with the conditions on which they will be licensed, may be obtained at this Department or at the Crown Timber Offices, Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

A. M. BURGESS,
Deputy of the
Minister of the Interior.
Ottawa, 14th August, 1886.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office up to noon on Wednesday, the 1st day of December next, for three timber berths of fifty square miles each, more or less, numbered respectively 16, 17 and 18, situated on the west side of the Columbia River, near Golden City Station, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position, approximately, of these berths, together with the conditions upon which they will be licensed, and the forms of tender therefor, may be obtained at this Department or at the Crown Timber Offices at Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

O'FICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

The death is announced of Mr. John Kelly, Deputy Commissioner of Mines for the Province of Nova Scotia. The late gentleman who was much respected has occupied this position for nearly a quarter of a century. Mr. Charles Carman, the deceased deputy's chief clerk, is highly spoken of as his probable successor.

At the annual meeting of the Iron and Steel Institute held in London on the 6th inst., President Piercy, the retiring officer, delivered an address on the iron and steel resources of Great Britain and the United States, and pointed out that British production of Bessemer Steel is rapidly decreasing.

We have observed with much satisfaction signs of improved methods being adopted for the development of our mining industry. During the past year substantial progress has been made. Our iron, copper, silver, gold, apatite, asbestos and salt deposits present a field for enterprise which has been too long neglected; and with the union of capital and skill we may confidently hope for the development of these resources, which, in the near future, will form not an unimportant part in advancing the welfare of the country.

At a great demonstration of miners held recently in the west of Scotland, a resolution was submitted regretting the continuance of low prices and consequent low wages; the evasions of the Truck Act, so common in the country, were strongly denounced and energetic measures to suppress the evil were called for. The reso-

lution also sought for the establishment by law of an eight hours day for underground workers. There was a considerable degree of earnestness and enthusiasm shown by the men, and the various speakers were warmly cheered when they referred to the hardships of the miners' lot and indicated the means by which it might be improved.

Nothing, remarks our esteemed contemporary the *Engineering and Mining Journal*, is more surprising than the tonic and strengthening effect of salt water or even a sea breeze on a gold or silver mine. A poor puny prospect-hole out west has only to cross the Atlantic once, and by the time it reaches London it is a "strong" and "healthy" lode, 'mineralized throughout,' full of "great strikes," and stronger and richer the deeper it is followed. From the merest shadow of a mine that would not yield "grub" to the industrious and abstemious Western miner, the sea air has invigorated it to such an extent that it not only can pay the liberal board of distinguished "guinea-pigs," but it promises a profit of from 20 to 50 per cent. on several million dollars of the worthy investors. We have not noticed that any physico-mineralogico-medical authorities have heretofore called attention to this curious and important phenomenon.

We continue to experience much difficulty in collecting correct statistics and other reliable facts in connection with mining operations in the Dominion; not that the information has been refused us in any case, but owing to the nature of it the owners and managers of mines neglect to furnish us with the particulars we desire. They appreciate the value of publishing reports of the mining industry, and wherever personal visits have been made they have been found willing to give details relating to the progress made, number and wages of employees, quantity and value of output, &c., &c. But while a personal visit to the various mines is desirable—and for gaining a proper knowledge of the industry, local observation and enquiry are occasionally essential—it is an expensive mode of ascertaining facts, and the great distances to be travelled in order to make a complete round of the mining centres of the Dominion would necessitate our employing a staff of representatives which we could not support. The progress of our mining industries is a subject in which the country at large has a deep interest, and the time has arrived when it has become necessary to organise a Bureau of Mines, in connection with the Geological Survey, with authority to make the supply of information compulsory.

Mining in Ontario is certainly growing in importance, though much more slowly than the extent and richness of her mineral deposits would warrant. Mr. A. Blue, Secretary of the Bureau of Industries, in his annual report to the Commissioner of Agriculture, declares that throughout the mining districts of the province,

as in the United States, speculation has been far more active than business enterprise, and adds: "It is easier to place a mine in the market for a million dollars than to sell it for a hundred thousand." The methods adopted for working mines have been, on a small scale, precisely the same as those pursued in the United States, on a large scale. The money required for prosecuting mining operations has been ventured in the hope of realising a speedy fortune from the discovery of a bonanza; operations are marked by rashness and extravagance, and too often end in disappointment and failure. In other words, plans are seldom laid with a view to the remote future, the desire being to produce the largest amount of bullion in the shortest time possible. The same experience is referred to by Mr. Clarence King, in the United States Census Report, recently issued. He says, after referring to the stability and steadiness of the mining industry in some foreign countries, "an engineer in this country is hardly to be blamed if he plans for the immediate present; on the one side he is pressed by the stockholders, clamorous for speedy profits, and on the other hand he realizes that the chances for a long period of bonanza are slight. His policy is forced upon him. He aims to secure given results by the most direct means, and when the object has been attained he cares little whether his drifts cave, and the structures over his hoisting works and mills fall in, if they have served their purpose." This, says Mr. Blue, is the record of Silver Islet, and East Silver Mountain, in the Province of Ontario, one of which has yielded millions of ore, and the other nothing beyond a rich surface show.

Insoluble Phosphate.

The following letter has been recently addressed to a gentleman in the Southern States by N. B. Powter, Esq., manager in New York of the Grand Cayman's Phosphate Co., of Kingston, Jamaica, W. I.:

MY DEAR SIR,—

You ask "why does the insoluble phosphoric acid in the natural West Indian Guanos give good results when sown with potash and ammonia, when the insoluble phosphoric acid in Charlestown floats, Canadian apatite, navassa and other rocks give no results although applied in a much finer state of division than the West Indian Guanos?"

In reply, allow me to state that the solubility of the phosphoric acid depends on two great points.

First: The amount of volcanic heat to which they have been subjected. For instance, apatite is the most insoluble of all forms of phosphate rock, and the most perfectly crystalized by volcanic heat. Then, next, those rocks which have been only partially crystalized, such as Charlestown rock, Navassa, Connetable, Swan Islands, phosphate of alumina from Germany, France, and Spain, and many others. But the natural fertilizers from the low lying islands, which all show that they are water formations and have never been subjected to any heat are very few in number and of small extent, and most of them so low in grade as not to pay to mine and ship.

Those best known here are Orchilla, Mona, Flamingo, Vivorilla (exhausted), Cay Avola (exhausted), Morant cays (exhausted), and now we offer the Grand Cayman's phosphatic guano, only recently discovered and of large extent. And this last is the only natural guano which is a compound of phosphate of lime, phosphate of alumina, and phosphate of iron, and these ingredients add much to its value as they help more on soils where the simple carbonaceous guanos have but little effect, such as marls and limes.

Secondly: The natural guanos are themselves soils which have been acted upon through a great length of time by the air, water, and action of vegetation. The mechanical condition is thus naturally suited to plant life, whereas the crystallized rocks before mentioned are often in great masses, as in connetable, the apatites, &c., &c. or are covered up in beds and pockets as in the Charlestown beds, Navassa, &c., &c., and are entirely useless in their present state for plant food.

Hence, although all are classed as insoluble phosphates by the chemists because they will not dissolve in water. Yet the natural guanos are all more or less soluble in citrate of ammonia solutions, and are fit for plant food as much so as the reverted phosphoric acid which is in the acid phosphates made from Charlestown rock, apatite, &c., &c.

Such being the case, I warn you not to be led astray by the statement that the insoluble phosphoric acid in Charlestown floats is as good as the natural guanos, for it has been proved over and over again that floats from Charlestown rock, apatite and navassa give no results, and as proved by the Georgia State experiments often make an actual loss.

I am, yours truly,
(Signed), N. B. POWTER.

[We publish the foregoing letter with the permission of its author, in order that our readers may have an opportunity to criticise in these columns the statements Mr. Powter makes. We have not the slightest doubt that he implicitly believes all the theories he advances, and in the interest of the Company he represents it is well that he should; on the other hand we have had the most positive assurance that experiments which from time to time have been made with Canadian apatite in its raw state have proved it to be very useful as a plant food the second year, and frequently the first year, after application. —ED.]

The Phosphate Trade.

The first shipment of Canadian phosphate went forward from Montreal on May 12th consigned to Hamburg, and since that date shipments have been irregular, due chiefly to the unsettled state of the British and European fertilizer markets, and the unusual fluctuations in ocean freight rates which have varied from five to twelve shillings per ton, and at this last high rate some of the later lots have gone forward. The market abroad has been in a stagnant condition during the past nine months and values have been reduced to 11d. per unit. for 80 per cent. phosphate, and with ocean freight at 8 to 12 shillings it is not to be wondered at that mine owners look upon the season's business with dissatisfaction. Notwithstanding this unfavorable state of things, viz.: reduced values and higher freights, there has been a fair amount of business done, which, however, must have proved

unremunerative to sellers.

Mine owners continue confident that there will be an early revival in the fertilizer trade and that better prices will be realized next season. This opinion is endorsed by dealers on the other side who report that indications of a re-action are already noticeable and predict an active market with the opening of navigation of 1887. Some of the producers have been averse to forwarding their output under the unfavourable conditions which have characterized the season's operations, and those of them who can afford to carry over until next year are wise if they have done so.

There has been no apparent relaxation in the activity at the mines; on the contrary, work has been carried on energetically throughout the past summer, and preparations are being made for continuous active operation during the winter.

The DuLievre Phosphate Milling Company have been much encouraged by the flattering letters they have received from customers, attesting to the excellent quality of their ground phosphate which they have received and used during this season. Shipments aggregating about 600 tons have been made to Boston, Buffalo, Detroit, Chicago and St. Catherine, and in every instance consigners have expressed themselves highly pleased, and affirm that they can use this grade of fertilizer to better advantage and with more satisfactory result than they have been able to obtain from South Carolina rock which they have been in the habit of using.

The demand for this ground phosphate will certainly expand, as there is every reason to believe that a large percentage of each year's production will be sold in this form, and that its principal market will be the northern United States. When such a market has been established it will very materially stimulate the Canadian phosphate mining industry.

We are not yet in receipt of a statement of phosphate shipments to date, but there is no doubt that the quantity which has gone forward for the season is considerably less than last year. Before our next issue will appear, the shipping season will have closed, and the November number of the REVIEW will contain a detailed statement of the year's output, and of all shipments for the season of 1886.

Asbestos Mining in Canada.

This industry is rapidly expanding in the Eastern Townships, and with the assistance of capital, and skilled labor it will assume larger proportions year by year. During the season of 1886, up to date, there has been greater activity noticeable at the mines than in any former year, and the result has been a marked increase in the production. The market, too, has been fairly brisk, and the demand abroad for Canadian asbestos is steadily increasing, as we find it to be superseding the Italian almost entirely.

Values have been steady during the year, and remain so, prices ranging from \$80 to \$50 per ton (2,000 lbs.), according to quality. A portion of this season's output is yet unsold although some of the most extensive operators have orders ahead for all they can produce up to the end of the year at current prices.

The Anglo-Canadian Asbestos Company (limited), are getting their mine at Black Lake well opened up, and will soon be in a position to largely increase their output. The steam drills, and air compressors which they put in last winter have given great satisfaction, and will ultimately tend to greatly facilitate mining operations.

The Scottish-Canadian Company, whose mine

is also situated at Black Lake, are preparing to put in machinery with a view to increasing their operation which are now under the superintendence of Mr. Chas. Lionais.

The Thetford mines, which are worked to a greater depth than has yet been reached at Black Lake, are still operated entirely by hand labor. In consequence of the greater depth from which the asbestos is taken at the mines in Thetford, the output is more uniform in color than that of the other mines of the district whose surface output requires to be classified as 1st and 2nd quality. The Black Lake mines are looked upon with much favor for future, and more extensive working, and when greater depth has been reached their product will unquestionably be of the highest grade. New uses for asbestos are being constantly discovered, but it is difficult to obtain accurate information in this connection until such discoveries have been worked out, and perfected, and but a small percentage of them prove of any practical value.

The output of the Canadian asbestos mines for this year, up to date, will aggregate about 2,000 tons, 500 tons in excess of last year's production for the entire season, and is made up approximately as follows:

	Tons.
Anglo-Canadian Company, Black Lake	400
Scottish-Canadian Company, "	200
Boston Asbestos Packing Company, Thitford	400
Johnson Company, Thitford	375
King Bros. & Company, Thitford	175
Ward & Company, Thitford	150
Jeffery & Company, Danville	200
Desultory mining, say	100
Total,	2,000

Coal in New Zealand.

In a recent report presented to the New Zealand House of Representatives by Mr. Larnach, the Minister for Mines, it is stated that in 1878 the total output was only 162,218 tons, but in 1884 it had reached 484,831 tons, and last year 511,063 tons. The consumption of the colony is still, however, in excess of the home production, and in 1885 130,202 tons were imported. The number of workings at present in operation in New Zealand is 95, and the output per man 345 tons per annum. Last year there was a strike at one of the mines, which resulted in a loss of production of 36,000 tons. In two cases the shafts reach a depth of 1,600 feet, and at that point the seam is from 17 feet to 18 feet in thickness. The industry is being conducted with a good deal of energy and enterprise, the best machinery being used, and it is hoped that before long the export of coal from New Zealand to the other Australasian colonies will assume some importance. It is acknowledged, however, that for a long time to come agricultural and pastoral industry will naturally claim priority in the application of capital and labour to the natural resources of the country.

The recent inquiries into the dangers of blasting have served to stimulate invention in the direction of mechanical "coal-getters." Several promising devices have lately been brought to notice of colliery owners in England and on the continent. Some of these are now undergoing the test of actual work. In the Westphalian mines particularly, attention is given to such machines, two or three of which have already won their way into favour. Foremost among these is that of Herr von Walcher. This apparatus, says Mr. George G. Andre, in the *Colliery Guardian*, is in regular use in three important collieries, from each of which have been received a highly satisfactory report of its working.

COPPER IN ONTARIO.

Extensive Deposits Near Sudbury.

DEVELOPMENT WORK BEING VIGOROUSLY PUSHED
WITH MOST SATISFACTORY RESULTS.

So much has been written within the past few weeks in the *press* regarding the copper deposits in the vicinity of Sudbury, and the reports have varied so vastly as to facts, that we will endeavour now to give our readers the benefit of the information we have been able to gather from other reliable sources as well as from a representative of the *Review* who has quite recently visited the locality in question with a view to arriving, as nearly as possible, at the facts as they actually exist.

The main lode, carrying yellow Sulphuret of Copper ore, has been traced by surface croppings for a distance of about four miles and extends from lot 5 in the 1st concession of the Township of Blezard, known as Stobie, or Mineral Hill location, south-westward to lot 2, in the 12th concession of McKim, known as Copper Cliff location. Another lode appears on the lot 11, in the 5th concession of McKim, about five miles from Sudbury, where it is crossed by the main line of the Canadian Pacific Railway.

THE FIRST DISCOVERY OF COPPER

in the district, according to a report by Mr. Blue, Secretary of the Ontario Bureau of Industries, was made at this point at the time of the construction of the railway. The deposit extends south-ward and east-ward until it joins the main lode of Copper Cliff, and on it are the McConnel and Fly Lake locations. Some prospecting has been done on these properties, but the only actual development work has been at Copper Cliff.

Mineral Hill location, about four miles north-east of Sudbury, was discovered and taken up by Mr. W. Stobie, in August, 1885. Here an opening has been made on the lode from the foot to the top of the hill on its south-east side and a test pit sunk to sufficient depth to reveal good ore. Proceeding south-westward, for a half mile or so, the Exposed Hill's location is reached, on lots 6 and 7 in the 6th concession of McKim, which comprises eight hills, extending along the north-west side of the north branch of Sudbury Creek, and embracing 6,500 feet on the lode. From both the Exposed Hills and Mineral Hill claims a fair quantity of ore has been taken out, and the assays have been very satisfactory. A line of railway has been surveyed for the main line of the Canadian Pacific Railway which will serve both these locations.

The Murray location, the property of Thomas Murray, M.P.P., of Pembroke, is crossed by the railway and shows out croppings of ore along its whole extent. Nothing has yet been done towards developing this claim, although this portion of the lode is regarded as very rich in copper.

On the McConnel location, which is on the same ridge as the Murray, two test pits have been sunk, penetrating bodies of high grade ore. To the eastward of the McConnel claim, two pits have been sunk on the Fly Lake location, lot 1, concession 3, of Snider township, the result of which has been to expose a sufficiently important ore body to induce the Canada Copper Company to pay \$13,000 for the entire claim, comprising about 1,800 acres.

THE CANADA COPPER COMPANY

is composed of wealthy United States and Canadian capitalists, and has been organized by Mr. Ritchie, of Akron, Ohio, President of the Central Ontario Railway. This company has already acquired the Copper Cliff, Fly Lake, McConnel, Mineral Hill, and one of the Exposed Hills locations, and will vigorously prosecute mining operations as soon as transportation facilities have been arranged by the construction of branch lines of railway. Already five locations on the main lode have been partially developed, one of which, the Copper Cliff, is now being extensively worked by the Canada Copper Company by means of open quarry work, which has been driven forty feet into the face of the hill, at a point where the vein is about fifty feet wide. About one hundred men are now employed, and owing to the very favourable position of the deposit at this point the ore can be raised at small cost, and in large quantity. Quite 2,000 tons of ore are now on the dump awaiting shipment, and the company is forwarding about 15 car loads daily to the smelting works in New Jersey. It is thought that ultimately the output of copper ore from this locality will find its way to Cleveland, and Detroit, as the reduction in freight rates to those points would be an important item. The distance by rail to Lake Huron is but 70 miles, from whence it can be shipped in ore vessels direct to the smelters. It is not unlikely that furnaces will eventually be erected in proximity to the mines, and the ore smelted there, and in the interest of the industry it is very important that some determined step should be taken in this direction.

The mineralized portion of the main lode in the Sudbury district is composed of yellow Sulphuret of Copper, (copper pyrites) intersected by strings of galena, and at some points measure from 40 to 60 feet in width of high grade of ore which will probably yield 8 to 15 per cent. of Metallic copper. Although these figures are infinitely below those which have been published, anyone familiar with the history of the important copper mines in other parts of the world will readily agree with us in the opinion that if the above data can be relied upon as the average character of the Sudbury lode, it will develop into a mine, or a number of mines, of gigantic proportions and unlimited capabilities.

Revival of the Mining Industry.

We are indebted to the *Engineering and Mining Journal* of the 2nd for the following:—"The great revival in business that has fairly taken root in this country has a more healthy tone and better prospect for enduring than the spurt we had a year ago. At that time, as we pointed out, every branch of business was lifeless throughout Europe, and so closely connected are countries to-day that no one can long enjoy great prosperity while the others are suffering from business stagnation. Our present active business is accompanied with a decided improvement and a better outlook in every European country. There is, consequently, good ground for the belief that we have fully entered upon a great wave of universal prosperity that will carry us forward for a few years at least.

We are not admirers of 'booming,' and we hope the present business activity may continue to increase at such an even and temperate rate that the wild excitement and violent fluctuations that are the symptoms of 'booming' may not be seen. A more active interest in mining and a greater desire to invest in mineral property have been very noticeable for some time past. We

are also advised from London that a real 'boom' has come over phlegmatic cousin John, and nothing is talked of but the great gold strike in the Transvaal, South Africa. It is said that the mine produces large amounts of seven-ounce rock. If this be so, it will go hard with the Boers to hold their country, and whatever the rest of the world may gain, they will probably lose.

But as 'one swallow does not make a summer,' so one find of seven-ounce ore does not create a rich mining country, though it is sufficient to excite the average London mining broker. The example of the Indian gold mines, in which so many millions have been sunk on the fortunate accident of finding one, but only one paying mine, the Mysore, among the vast number of prospects sold at the prices of good mines, makes it probable that a fresh lot of good money will go out from that great paradise of worthless mine vendors. It is safe to predict its principal return will again be the valuable but unheeded experience that prospects are not mines; that an investment in the shadow of a neighboring bonanza is the most unsubstantial of values; that the prospectuses prepared by London 'promoters' are generally works of pure imagination and financial will o' the wisps; and that no public mining investment is worthy of attention unless the value of the property has been ascertained and is vouched for in detail by competent, disinterested and honest experts.

But it is not our province to warn Englishmen of the shoals and quicksands that surround Indian and African mining speculations. Nor is it possible for us to buoy every sunken reef that will wreck so many English investments in this country. For some time past, American mines have found ready sale in London, and for the most part, those offering there are either absolutely worthless, as in several cases we have exposed, or are so vastly overvalued as to be little short of swindles.

It is the old story over again: 'It is all but impossible to sell a mine in London at a fair and honest value.' And American mines are brought into disrepute by the dishonesty of those who float worthless property there, and the unquestioning credulity of those who invest on their 'fish-stories.'

Mining never was more prosperous in this country than it is to-day, and there is no other kind of investment that offers so large a reward as that prudently made in mineral property, neither is there any other country in the world that has so many good mines or offers so many of the elements of success and profit to the investor.

Products of Bituminous Coal.

"Few persons, says the *Chicago Mining Review*, have an idea of the wonderful products from a lump of coal—a lump of coal that is placed in the retort of a gas manufactory. Ordinarily burned, the combustion of a lump of coal results in carbonic acid smoke (which is merely soot, or rather the visible portion of smoke is soot), and the ash, in which are found silica, alumina, oxide of iron, phosphoric acid, sulphuric acid, potash, sodium, combined sulphur, sometimes traces of chlorine, titanate acid and other substances. In the gas retort a variety of products are obtained. The gas as it is carried through the hydraulic main to the purifying rooms takes with it tar and ammonia, the latter evolved from the nitrogen. Ammonia has to be washed out with water in an arrangement by which the ammonia is gathered and saved. Tons and tons of sulphate of ammonia are thus made and become an

article of commerce. The sulphur is removed by caustic lime or oxide of iron. The carbonic acid is also removed by lime, but the carbonic acid cannot be removed, and with several others remain in the gas after all efforts to remove it. The others give the gas its smell.

By distillation naphtha and asphaltum are obtained. Asphaltum is a dead oil, very useful to preserve wood. From this, too, carbolic acid is obtained, very important in surgical operations as being the most valuable antiseptic known. From naphtha, benzole, eumol, teluol and cymol are obtained. Naphtha, as is well known, is used as a burning fluid. Benzole is a solvent for grease and oils, very useful in cleaning kid gloves and things of that kind.

Benzole treated with nitric acid produces nitro-benzole. This singularly enough, is used as a flavoring extract by confectioners and for perfuming soap. When used for this purpose it is known in commerce as the essence of myrrhbane, which it is not, although it smells and tastes something like essence of myrrhbane or oil of bitter almonds. Nitro-benzole is terribly poisonous but not more so than some other adulterants used by confectioners.

From nitro-benzole analine is obtained. This when first obtained is a perfect colorless liquid but darkens as it grows older. From analine are obtained the coal-tar colors, which are so very brilliant. The colors are of all hues. The one known as 'turkey-red' is exactly similar to the red that used to be made from the madder root. Since the discovery of this analine it has almost completely broken up the raising of madder in Holland. There, thousands of acres were devoted to the raising of madder root to get the turkey-red dye. It can be made much cheaper from the product of a gas factory."

Henry George on Miners.

In the *North American Review* for September Mr. Henry George, the well known author of "Progress and poverty," and other politico-economic works, makes some startling revelations of the condition of labor in Pennsylvania. His investigations have been mainly among the mining class, which numbers many thousands of men, most of them with families depending upon them. Mr. George, before going into details, calls attention to the extraordinary natural advantages of that great state. It is nearly as large as England, and in the fertility of its soil its mineral wealth and commercial position stands second to no state in the world. It has a fine population of four millions and a half, a mere fraction of what so rich a state is capable of maintaining. If anywhere in the world, labor should there enjoy the greatest rewards. Poverty and pauper wages should be things unknown. But mark the actual state of affairs among the mining class. Pennsylvania is the greatest coal-producing state of the union. She has almost a monopoly of it, especially in the article of anthracite. She has enjoyed (to use a phrase that is becoming ironical) the most stringent protection. And yet her miners are to-day in a condition the most pitiable imaginable. They are the abject, helpless slaves of the great coal kings, men who own whole counties and against whom the power of labor unions is exerted in vain. Mr. George cites the case of a mining strike among the workmen of one of these anthracite magnates who, refusing to listen to the men's complaints, swore he would burst the strike or turn the country into a desert. As he was the owner of whole mining townships and could apply the screw of eviction even more remorselessly than an Irish landlord, it is needless to say that he burst the strike.

The tenements supplied by the great coal men to their workmen are pictures of squalid wretchedness. Workmen have no chance to become property owners themselves because the coal proprietors will not sell, and even if they would the workmen can never save money. Protectionist quotations of their high wages are entirely fictitious. The wages the miners are supposed to receive are in point of fact about double what they actually get. For out of his wages the wretched coal miner has to pay for his own explosive, for the sharpening of his tools, and for the coal he consumes. In England, coal owners have to bear these expenses themselves. Then, too, in Pennsylvania, a system prevails of deducting from the men's pay for impurities in the coal which has become a most tyrannical abuse. Each man has a car with his number attached, and as the car is drawn from the pit it is examined. The smallest piece of shale or the slightest shortage in weight damns the whole load. The miner gets nothing for it and the coal owner gets a car-load without costing him a cent.

The most flagrant abuse of all is the system of company stores. The coal owners maintain establishments for supplying the general wants of the miners, which, from their extortionate nature, the miners have dubbed "pluck me" stores. Prices in these establishments range from 15 to 100 per cent. higher than elsewhere, but the miner is powerless. He must deal at the "pluck me" store on pain of losing his occupation. He seldom sees a cent of his wages. Only the difference between his account at the store and his wages ever comes to him, and oftener than not his account is greater than his wages after the latter have been subjected to the deductions mentioned before.

To fight the coal owners is almost impossible. Legislation could help the miner, but legislation is controlled by the giant monopolists. The latter are all powerful. Sheltered behind the protection screen, they fear no competition. They control the market for their coals, but the only commodity the miner has to sell, his own labor, is left defenceless. On the slightest provocation, indeed without any provocation whatever, Bohemians and Hungarians are introduced to work the mines at wages upon which the Americans cannot exist. In England, where wages are in reality but little lower than in Pennsylvania, and where money goes a great deal further, no one hears of the importation of Bohemian and Hungarian miners. The reason is that in Free Trade in England it is more profitable to employ the best men that can be got, and the English miner is doubly as good a workman as the half-starved Bohemians and Hungarians. In Pennsylvania the coal monopolists are under no necessity of employing the best men. They are sure of their market and consequently are sublimely indifferent to the class of workmen they employ. Protection is bearing its bitter fruit in Pennsylvania.

Deep Shafts of the World.

Western miners have in ten years accomplished nearly as much as has been done in Europe in three centuries. At least such would be the inference when a comparison is made between the deepest workings of the old and new world. The deepest shaft in Europe is the Adelbert, at Prizbam, Bohemia, which was started in the sixteenth century, and has a depth of 3,280 feet. The greatest depth obtained by a shaft on the American continent, is the Combination shaft, on the Comstock, which was begun ten years ago and is within thirty-seven feet of being as deep as the famous ancient hole on the other side of the waters.

Mining in Australia.

"PENDRAGON" AT BALLARAT, AND HIS DESCRIPTION OF THE WORK AT THE FAMOUS BAND AND ALBION GOLD MINES.

The following letter by the gentleman who edits the "*Referee*," under the well known *nom de plume* of *Pendragon*, and who is now travelling in Australia for the benefit of his health, is so interesting that we reproduce it for our readers in full.

"When we went to see the Arts and Sciences Exhibition at Melbourne the sight which 'took' my companions far and away above pictures or sculpture or designs or models or anything of that sort, was a case which contained gilt casts of the most celebrated nuggets found in Victoria. About this they hung and hovered. I went two or three times round the show, and always found them in the same place, examining the nuggets, reading how one or other of the most weighty among them had been come upon suddenly and without any premeditation, how another had been found within a few feet of the surface, and so on through the list of auriferous discoveries, the stories of which are often really interesting, even to the mind which is free from the gold fever, now fast spreading again throughout the continent of Australia. There were my couple, oblivious of anything else, calculating the value of each nugget, and reckoning what they could do with the money. The result of all this was that nothing would satisfy them but they must go to Ballarat, the nearest place to Melbourne in which gold mines are now to be found; and as it has been in everything else since we started, the will of the majority—I am ever in the minority—carried the day. So we prepared for Ballarat. It was in vain I explained that nuggets are not found in such mines as exist at Ballarat; that the difference between operations in the quartz and the alluvial is such as to make the journey (from their particular point of view) fruitless.

In due course we arrived at the Band and Albion mine (or claim, as such ventures are still called here), the biggest and most successful of the shafts in this neighborhood, and, having presented our papers, were permitted the pleasures of an inspection. There is no necessity for me to go through a description of quartz-crushing, the throwing down of the gold by its own weight, its attachment by means of mercury, the searching and attracting process of the shaking tables, or any of the other means to the end of obtaining the precious metal from crushed quartz and its accompanying pyrites. Anyone who wants to know all about these things can find them set out fully and far more effectively than I could set them out, even if I had space, in books and treatises devoted to mining in all its ramifications. There is no necessity for anyone to come to Australia to see the battering and extracting processes; thousands of tons of quartz are sent home to be crushed and washed and assayed, and whatever else is necessary, by English means and machinery. Suffice it to say here that what my companions saw was widely different from what they expected. All their dreams of men shovelling up earth, from which they picked great lumps or small lumps (but always lumps) of bright red gold—dreams which I had vainly endeavored for days to show were dreams and dreams only—vanished directly our guide began to explain the mechanical appliances, the way in which the pyrites detritus is dried and ground and made into boiler paint, as well as the rest of the details which must be familiar to so many. There can hardly have been an exhibition of any

importance in England or out of it during the last thirty years but has contained models, often in actual work, of these various machines, together with all sorts of samples and specimens of the results attained by them. Presently, however, we did see something that was interesting even to me. By great good luck we arrived on the ground just as the battery manager was going through the concluding portion of his smelting operations for the week—once every seven days the Band and Albion people cast into a solid block of metal as pure as it can be got the result of the week's mining, blasting, battering, throwing down, mercury-attaching, and shaky-tabling operations. When we got into the room sacred to this smelting work the gold was bubbling in a crucible, just like broth simmers in a pot. Every now and again, as the furnace man threw in the saltpetre, borax, and whatever else it is that is used to give the last purifying touches, or withdrew them with their metallic attachments, we were permitted a peep at this precious liquor, which, before we had been there very long, was ready to be turned out into the in-got mould that, greased for the purpose, stood ready to receive it. With a strong and steady grip of the tongs, and without any apparent care for the intense heat which, when the fire was at last thrown open, seemed as though it would burn the eyes out of our heads, though we stood at some distance away, the manager took up the crucible and poured the most valuable stream I ever saw in my life into the mould, where, after giving off as many colors as a dying dolphin, it was soon cooled. When weighed, the tally was 400 ounces, or say £1,650 sterling worth of gold, which may be taken as a fair average for recent years, though in days gone by they have in a week secured as many as 1,000 ounces. In the period of the alluvial, before the quartz reef was struck, when nuggets and dust came up by the bucketful, the Band and Albion was still more profitable. The yield is now about an ounce and a quarter of pure metal to the ton of quartz. Besides the gold, the pyrites, as I have already intimated, pays for the work expended on it. Fifty per cent. of the result may be taken as the cost of working. Thus, 200 ounces of the 400 ounces we saw turned out would be net profit—that is, profit over and above the expenses of men and machinery. As the mine paid almost from the first sinking—Band of Hope, it was then called, and a junction was afterwards effected with a neighbor, the Albion—the number of proprietors and the amount of capital invested are sufficiently small to make this very profitable. In proof of this, I will conclude with the announcement that, during its twenty years of existence, the Band and Albion has produced no less than twenty-six tons of pure gold.

Since the day of our visit I have often wondered whether, if I had refused to go, and the other two had, as they insisted they in such case would do, gone by themselves—whether either or both would at the last moment have gone down the shaft. I don't like to be unjust, but I certainly don't think both of them would have gone, and I hardly think one would have gone without the other. After inspecting the stuff that came up from the mine, all their preconceived as well as their last lingering hopes of nuggets, or even of bits of gold no bigger than pins' heads, had departed, and there was really no reason whatever for going down beyond the reason that you could say you had been down afterwards; and that, as we have good authority for knowing, can always be done without the actual trouble of descending into the earth's bowels. Now came my opportunity. This was not a venture of mine—far from it; I had for a

variety of reasons never encouraged it, but having got so far I had not the slightest idea of turning back until the work was accomplished. It was necessary, owing to the constant dripping of water both in the shaft and cuttings which led from it, that we should cover ourselves up, and this we did with as grotesque a collection of old clothes as ever was got together. To enter into details is hardly necessary; but to make the picture completer I may as well tell you what our outfit was. Dirty overall trousers of canvas, an old pair of what are called half-boots, but which were in this instance quite big enough to be whole ones, and a white (or what had once been white) duck jacket, the look of which I wouldn't have minded at all if it had been but dry—it had been used in the morning by one of the directors and I had to wring the wet out before putting it over my own clothes—an old sou'-wester, and my preparations were complete. Mrs. PEN. got a skirt and a waterproof cloak, and an old bonnet; in Covent Garden so attired she could easily have obtained work shelling peas or carrying baskets. Except that his costume was not so new as the clothes usually worn by him, and that they were not made by Poole, I did not notice any particular change in Mr. Stephens' appearance.

When people go down a coal mine in England, and think they have done something wonderful, they go down a wide, well-drained and equally well-ventilated shaft, seated in a comfortable cage—they might almost be in one of the lifts at the stores so far as concerns lack of violence to their feelings. Here all was different. There was no cage, nothing but the cross-bar, or 'saddle,' upon which the galvanised iron troughs came up full of quartz or went down empty. The shaft was not above four feet square, and as we took our stand upon the wet and dirty piece of iron from which a trough was shifted to make room for us, the water from above poured on us in streams. Mr. Stephens elected to wait above until we had gone down, and so Mrs. Pen. and myself, in company with a guide, departed. There was plenty of room for four of us, standing close together, as was shown by us all ascending on the one 'saddle,' but S. G. prefers to do things his own way; he has done them his own way as far as we have gone, and there was no reason, I suppose, why an alteration should be made in this particular. No matter how crowded on the "saddle" you may be, you can't fall off, as there isn't space enough, but you might easily get your head knocked off, or meet with some similar slight disadvantage, if you did not keep quite steady. Down—down—down, in absolute darkness, for about a minute, when the platform on which we stood gave a lurch and a swing, which made my wife tighten her hold on me and give vent to a smothered groan. 'We are now six hundred feet down—I know that mark well; it was there'—and then, as though that story might not be exactly what was fitting under the circumstances, our guide broke off, and we went on in silence. 'That's the thousand-foot mark,' said he presently; 'another hundred—' And hardly had the words escaped him than we bumped upon the hard earth at the bottom of a pit eleven hundred feet deep. Mrs. Pen. would have been very glad to get out at the bottom if she hadn't been so awfully troubled by the knowledge that she had to get to the top again. Mr. Stephens having in due course joined us, candles were handed round and lighted, and we went upon our travels. And we might just as well have stayed up above for all there was to see below. The cutting is very small, just big enough to allow the troughs containing the

quartz to run on a two-foot tramway, and the water is always four inches, and sometimes six inches, deep throughout. Often we had to get down and almost crawl, and the number of times I had to stoop in the ordinary parts so as to avoid knocking my head made me feel like a veritable Gulliver in the neighbourhood of Blefuson. We had to do almost as much wading. Mrs. P., who had not changed her boots, and who flatly refused to get into one of the troughs and squat down in the wet bottom so as to let her head go free under the drooping roof, soon had to be left in a safe corner trying to pick pieces of gold out of the quartz wall, while we pushed on to see what we could see where the miners were working. After desperate struggles we at last came to that part of the reef which was being operated upon, and there being no fans or other apparatus for ventilating the mine, and it now being very far from the shaft, the heat was intense. One of the men at work, in reply to my comment on the heat, took up his shirt and wrung the perspiration out of it. I climbed up a rude scaffolding and got into a hole where a man sat, chip, chip, chipping all by himself, but I might just as well have got into a baker's oven just before drawing time, the heat was that intense; so I came away again. After a rest for a minute we partly waded, partly crawled, partly groped our way back again to where Mrs. P. stood in agonies of apprehension and little less than a pool of water. She had wandered from her coigne of vantage, a rush of air had blown out her candle, and visions of all sorts of dread and danger gibbered and made darkness horrible around her. As soon as we got to the bottom of the shaft we huddled together, and, drenched and miserable, in due course reached daylight again, without anything worse having happened to us than I have described. In lieu of nuggets Mrs. Pen. and Mr. Stephens found some really fine specimens of the nasal and bronchial catarrh, and they now bark and snort and grunt and talk through their noses, and drink hot rum with honey and butter in it, and buy all sorts of cough and cold specifics, and have their feet in hot gruel and bran mash, and stick mustard plaisters all over themselves, and generally make their wretched travelling companion's life intolerable. And through it all they pretend now that they thoroughly enjoyed themselves. I know I didn't; and I don't suppose for a moment they did."

Mining in British Columbia.

Extracts from Mr. Koch's valuable report to the Local Government on the Cariboo Quartz Ledges.

PATENT PROCESSES.

"I must give you warning by calling your attention to the many processes being placed before the public, or before men not skilled in such business as mining and milling ore, for they are the only ones who can be led astray into such wild and impracticable schemes as some of the processes are.

"I will refer you to some of the failures, and if your memory does not serve you well in the matter you can get full particulars from Wm. Ireland, jr., State geologist of California.

"The first one in my mind was introduced by a man I think named Mears, in Chili, ten or more years ago. He became the rage in that great mining country. His process was, of course, a secret. His trials, like all such, were however public; even those likely to fall into the trap were invited to make tests for themselves, all with good results.

"Many wealthy men became bankrupt by buying mines which were too poor to be worked by ordinary process. The promoter was presumably interested in such sales. The matter became so public, and so many had invested their all, that an investigation was had, which resulted in the fraud being exposed and the promoter sent to prison, and, if alive, he is perhaps there yet.

"Among the more recent patent processes is the Frier process.

"Some twenty-two years ago, Meadow Lake district was discovered in the Sierra Nevada mountains, about thirty-five miles from the Central Pacific railroad. The veins were extremely large and well defined, many of them rich. A large town grew up, as it were, in a day; mills built and mines opened, when, to the consternation of all, the ores were found to be refractory, and up to this time they have baffled the most skilful manipulators. About ten years ago, a man named Frier gave out that he had discovered a process by which the ore could be worked. I, with many others, think that he was honest in his belief; but after men of means had spent thousands of dollars in the erection of reduction works it proved to be an utter failure, and to this day, the rich veins of Meadow Lake lie dormant. A San Francisco company by latest advices are shipping in, and erecting a mill, to cost one hundred and fifty thousand dollars. Let us hope the mystery has been solved as to the proper treatment of the ores.

"A more recent process is one started some five years ago in San Francisco and lately revived in Victoria. I had the satisfaction of investigating it some time ago, soon after it was made public. Small works were erected in Sacramento, but never started.

"It was taken east, and I was told that Jay Gould, and other moneyed men, all ignorant of such matters, took stock, and erected works in Colorado. If so, they quietly closed them down; not one of them is at work either in California, or, to my knowledge, in any other country in the world. Every mining man in the world would hail with delight such a process if it were feasible.

"I cannot well afford to make the effort I am now making on behalf of your people, and government, and see my work hampered by having some patent process sprung upon the public, and proved to be an unmitigated failure after costing individuals or the government thousands of dollars; and the fault be laid on the mines as being valueless. I refer those that have witnessed the process, and feel anxious to investigate, to such men as Wm. Ireland, jr., State geologist; Prof. Price, assayer and chemist; C. A. Luckhardt, of Nevada metallurgical works, and H. Kustell, assayer, all prominent men in that branch in San Francisco. Either will be pleased to give them information on the subject.

"I must not let any patent process escape me for fear you may deem it applicable to your ores, because I neglected to report or state my views on the subject. I therefore call your attention to an article in the *Mainland Guardian* of July 31st, 1886.

"I do not deny the possibility of saving the gold by the process referred to in the article; but the very fact of the pulp or ground ore having to pass over a bath of melted copper explains at once that the ore must be dry-crushed, that process at once reduces the crushing capacity of the mill over one-fourth as compared with wet-crushing; and the same per diem cost of fuel and skilled labor goes on.

"Next, in order to reach the gold, all the crushed ore, sulphurets, and vein gangue alike must pass over the molten bath which requires

fuel and skill to keep to the requisite temperature as well also does it require skill to keep the pulp passing evenly over the bath, and lastly when your gold is gathered, you must resort to the expensive method of parting the precious metals from the copper, which process alone would go far towards de-sulphurising and chloridizing as now done in California.

DIFFERENCE IN COST OF MINING IN BRITISH COLUMBIA AS COMPARED WITH CALIFORNIA.

"In the absence of statistics, I will attempt to show the difference in the cost of mining and milling in California as compared with Cariboo, and the very probable results to be obtained from the energetic, careful and scientific handling of your large and well defined gold-bearing veins.

"Skilled labor, which includes mechanical engineers, smiths, millmen, and chloridizers costs, in California, about four dollars per diem.

"First-class miners and blasters cost \$3, and second-class from \$2.75 to \$2.50. Outside labor, including Chinese, averages \$2 per diem. Wood, for steam purposes will, no doubt, average, at this time, five and a half dollars per cord, while the ores milled do not, in my opinion, yield to exceed eight and a half dollars per ton. That estimate may seem small to a California miner, but when it is remembered the enormous quantities of low-grade ores milled by such companies as the Plumas-Eureka, Sierra Buttes, Douglas Island, Doctor Zielie mine, and many others, it greatly reduces the average as compared with the few stamps milling \$12 to \$20 ore. And yet the far-seeing capitalist of California finds investment in a quartz mine one of his best investments, and does not hesitate to erect the best machinery that skill can invent, whereby mining may be made a legitimate branch of industry; and my examination of your veins has led me to carefully study the situation as compared with the above. I find skilled labor, as above, will perhaps cost \$6 per diem, good miners \$4, second-class \$3.50, while outside labor costs \$3, and wood not to exceed \$3 per cord.

"While I feel safe in placing the milling value of your ores at from \$17.50 to \$20 per ton, and I feel confident that those figures can be safely advanced from ten to twenty per cent., but I have endeavored to be cautious in the examination of your mines, and my statements to your people, and do not wish to cause them to be over sanguine until milling results are reached. I have made the above estimates as to cost after talking with your most prominent citizens, and estimate the value of your ores after making over fifty assays from the different veins, and carefully testing the feasibility of chloridizing the sulphurets contained in the ore.

MINERALOGICAL SURVEY.

"I deem it of the greatest importance to the province that a systematic mineralogical survey be made, not alone of this immediate vicinity, but of the outlying and surrounding country. The survey should be so managed as to keep pace with the prospector, rather than neglect the work commenced by extending the examination too far beyond present work; for, by extending the survey beyond present developments, you deprive the prospector of the assistance and advice of your engineer.

"As I have previously stated the government can materially aid and assist the prospector in his work of development, and often save him much time and money by having an intelligent and practical engineer near by to consult and to

advise him as to the best method to prospect his ground, and as to the probability of reaching pay-ore.

"In this connection I will state that I see a bill is presented before the house in New Zealand whereby it is proposed to appropriate one hundred thousand pounds to aid in developing the mineral resources of the colony; while the United States has, perhaps, the most complete and extensive mineralogical survey system of any country in the world, and the result is—what? English and French capital come to the United States in preference to any other country. They read, and have the mineral resources of the country explained to them constantly.

"Following upon the heels of the annual mineralogical report, enterprising men go to London and Paris well supplied with samples of ore, and elaborate maps of mining property, and gifted with national go-ahead-iveness and never-let-go, they annually induce a large amount of capital to come into California, Nevada, Colorado, Idaho, New Mexico and Arizona. Not one of these states or territories but have large English and French companies successfully at work; and the more capital they invest the better they are pleased in case it yields from six to ten per cent per annum.

"The capital can be turned hitherward; not, however, by sitting supinely waiting for its coming.

"Ask an Englishman which he would prefer—Canada or the United States, and why, and he will answer "The United States, because there is more dash, enterprise and go ahead amongst the people." Including Alaska, Oregon, California, Idaho and Montana, mining industries have almost surrounded you, and the outside world scarcely knows that you are the possessors of such promising and well-defined gold and silver-bearing veins.

"Several years ago so eminent a man as Prof. Dawson took with him to Montreal samples of the quartz broken from the croppings of your veins, and reported to you from five to six dollars per ton, and encouraged you to hunt in those veins for richer ore, as they were, beyond doubt, the sources of the many millions of coarse gold intermixed with quartz taken from your creeks and benches, and no richer placer diggings were ever discovered than your creeks and benches through which the veins pass. Do not forget that the mountain will not come to you; on the contrary you must seek capital and give it encouragement, and the day will come when your district will again rank as formerly amongst the great gold producers.

"Capital, at present, is seeking investment in the most remote corners of the globe. All manufacturing industries are overdone. Silver is a drug upon the market and can scarcely hold its place as a circulating medium, while, (including the product of the entire world) gold enough is not now produced to supply the arts and sciences. Then why not use energy and push enough to induce English capital to come to your district?

"In referring to capital seeking investment I may refer you to the circumstance of an English company formed to work the gold quartz found in South Africa. In order to be well equipped in every detail, their mill was built in San Francisco, shipped overland to New York, thence to England and transhipped to Natal on the south coast, where it had to be hauled by cattle seven hundred miles inland. Also, one of a hundred stamps and necessary amalgamating pans was built in San Francisco and shipped to Peru, where, by rail and mules it had to reach the giddy height of thirteen thousand feet, near the

summit of the Andes Mountains, to work a silver mine.

MANAGERS OF MILLS AND MINING PROPERTY.

"I can not too strongly impress upon the minds of those proposing to invest in, or operate mines, in this district, the great importance of selecting none but the most competent of men for their managers. They should come with good references as to ability and integrity.

"Favoritism, friendship, partnership, good honest men and too old to work, and such like considerations that can be advanced for making appointments, which might lead to the ruin of a company, or, at least, the useless expenditure of thousands of dollars, should all be discarded.

"The day is past for appointing ministers out of place, highly-educated physicians and lawyers or rich men's sons just out of college, because their fathers are largely interested.

"Appoint some man who has had years of experience of vein mining, one who has cost some San Francisco or Eastern company half a million of dollars by some blunder made years ago. He has had experience, and blushes, and wonders how he could have made such mistakes as he has. He will, even now, make small mistakes, but he is quick to discover and remedy them. Good men can be procured, men that have worked in and helped to open the finest mines in the world.

"A manager should be able to run an engine, know how to run a mill in all its branches, know when each stamp is doing duty, detect a loose mortar bolt, cut out any kind of timbers for shaft, drift or elsewhere, sharp a pick or drill, and, in fact, he must, be a miniature encyclopædia, and he must be honest, temperate and kind.

Meeting of the Austin Mining Company (Limited.)

The annual general meeting of the shareholders of this company was held at the company's office in Ottawa, on the 28th ult., the meeting being largely attended by those interested. Little was done beyond the election of directors, the new board being, Hon. W. A. Henry, G. H. Perley, J. A. Gemmill, E. Grant Powell, J. F. Nellis and G. F. Austin. The operations of this company have been much hindered and obstructed by the action of some of the holders of paid up shares, but now that the management has got into the hands of capable men it is to be hoped there will be no further obstruction, and that capital may be secured to put the property on a working basis.

Alfred Krupp, the world famous German miner and manufacturer, employed in 1881 no less than 19,605 hands, upon whom were dependent others to the number of 45,776. In other words, the people whose bread is earned in Krupp's works, would fill a city of 65,381 inhabitants.

The *London Iron Trade Exchange* says, "that returns of the mineral production of France in the first six months of the year show that the output of coal was 9,696,573 tons, an increase of 319,862 tons on the same six months of 1885. The manufacture of pig iron fell from 829,366 tons in 1885 to 763,225 tons in 1886; puddled iron rails from 1,468 tons to 480 tons; merchant iron from 332,795 tons to 326,023 tons; sheet iron from 59,829 tons to 47,620 tons, and steel rails from 182,084 tons to 146,269 tons, and steel plates from 25,638 tons to 22,987 tons. The production of merchant steel rose from 4,237 tons last year to 55,538 tons in 1886."

MINING NOTES

Nova Scotia.

The main shaft of the Cowan gold mining company has already yielded upwards of \$20,000.

The Annapolis *Spectator* announces the discovery of a rich lead of gold bearing quartz in Caledonia. The samples shown by Mr. Charles Ford, of Maitland, are said to indicate unusual richness.

We learn from a recent issue of the *Critic* that Mr. R. Macnaughton has brought to Halifax 600 ounces of gold, the September product of the Rawdon Mines, and that a new 25 stamp mill is now in operation there.

A local exchange informs us that a brick of gold weighing 319 ounces and valued at over six thousand dollars was brought to Halifax, N.S., from the Oxford mines at East Halifax. It represents thirty days' work of three men.

The work at the Coxheath copper mine of cross cutting from the shafts at the 200-foot level directly to the new vein, 70 feet north is now being carried on. Some 180 feet has already been accomplished, proving the continuity of the ore body for that distance.

On Wednesday, 22nd ult., a fire broke out in one of the engine houses at the Albert mines, Albert County, and five buildings, including engine house, blacksmiths' shop, carpenters' shop, a dwelling and store house were completely destroyed. No estimate has been given of the loss, which is not covered by insurance. It is thought that the conflagration was the work of some unknown incendiary.

The gold mining outlook, says the *Critic*, grows brighter and brighter every day. New finds are frequently reported, and best of all the capital to develop them is at once forthcoming. The find at Malaga Lake, in Queen's County, is likely to prove one of the richest in the Province, but unfortunately it seems destined to undergo the same trials as the famous Salmon River mine. Rival claimants are in the field, and as the property is undoubtedly very rich, a settlement will hardly be reached without an appeal to the courts. Under the system at present in vogue of taking up mining claims, it is the easiest thing in the world to put in a bogus application and force properties into litigation. No capitalist will look at a mining property in the title to which there is the slightest suspicion of a flaw, and, taking advantage of this, unprincipled men make a contest on the most frivolous pretext and often succeed, where the real owners are anxious to sell, in forcing a compromise and getting an entirely unmerited share of the mine. This business has been reduced almost to a science, and if not put a stop to in some way, is bound to do immense harm to the gold mining industry. We do not know that these remarks apply to the Malaga Lake contest, as we are not familiar with the points at issue, but we do know that similar tactics have succeeded in numerous other cases.

A radical cure must be found for the evil, and we would almost favor making it a penal offense to put in a bogus claim to a mine. In most cases it is simply an attempt to extort money through false pretenses, and should be punished accordingly. A party contesting should be obliged not only to furnish security for costs in case he failed in the suit, but also security for any damage that the owner incurred through the contest. This alone would prevent any but *bona fide* claims being raised. Time is everything to a mine owner, and any disputes should be adjudicated upon at once, and it might be well to have them referred to a mixed board of arbitrators, composed of mining experts and judges of the Supreme Court, where decisions in all cases should be final. When the Mining Association is organized, this subject should be one of the first to demand attention. It is an easy matter to drive capital away from a country, but a most difficult matter to restore confidence where it has once been lost. Outside of this one cloud of litigation, the mining horizon is clear. The capitalists now investing their money in this Province are also practical miners, and are not to be made the dupes of dishonest men. The day of the cunning mine manipulator has gone by and the best proof of the value of the gold mining industry in Nova Scotia lies in the fact that mines are now bought and sold solely on their merits.

New Brunswick.

The mines at Markhamville are said to be shipping manganese all the year round.

Operations at the manganese deposit near Sussex have been suspended, pending an equity suit. The mine has been leased and worked by a Mr. F. W. Stockton, but another mining expert claims an interest, which is repudiated, and hence the action.

Quebec.

A new company styled the St. Lawrence Corporation (Ld.) has been organized in London, Eng., with a capital of £100,000, 100,000 shares of £1 each. The objects of this corporation are to purchase, lease, or otherwise acquire, hold and work timber and other lands, mines minerals, hereditaments, and premises in the Dominion of Canada, and in particular the lands and estate known as the Mille Vaches Estate, in the county and district of Saguenay, bounded in front by the river St. Lawrence and behind by the public domain, on the south by the township of Iberville, and on the north by the township of Laval, together with all the timber, and all minerals on and under the surface, the houses, and other appurtenances, and all rights, and to acquire and undertake all or any of the assets, debts and liabilities of the Dominion of Canada Freehold Estate and Timber Company, Limited.

Ontario.

The first shipments of Canadian Iron ore to Lake Erie Ports was made to Cleveland last month and consisted of 540 tons. The mines on the Central Ontario Railroad, owned by a Cleveland Syndicate, have been shut down owing to a cessation of demand since last March. The *Cleveland Iron Trade Review* says that during 1885, 10,508 tons were shipped from these mines, of which 100 tons went to Bessemer, Pa., and the remainder to Cleveland. There were mined, however, during 1885, 32,059 gross tons, of which 3,752 tons were second-class ore. It will thus be seen that 21,551 tons were added to the stock-piles last year, besides the amount mined from January 1st to March 31st inclusive,

this year. It is understood that the cessation of demand for this ore was owing to the presence of titanium, which rendered roasting necessary, and that no more ore will be mined until that on hand is first roasted. It is also known that the ore already delivered on Cleveland blast-furnace docks is roasted before using.

THUNDER BAY DISTRICT.

The mill at the Rabbit Mountain Mine is now running very smoothly and is said to be stamping about \$250 a day.

Messrs. Harvey & McInnis are having their property at Silver Mountain surveyed, and as soon as the waggon road is constructed they will proceed with the work of development.

Mr. H. Wilson, of Mount Forest, reports that a stock company, with a capital of \$150,000 has been formed to develop the Heron Bay Mine. This property is very conveniently situated close to the railway station.

A new Prospect is just being opened on the Port Arthur side of the Beaver Mine. Messrs. Crawford & Corbett are taking out rock bearing quantities of argentiferous galena. Some very fine specimens are being shewn.

Mr. T. A. Keefer has commenced operations at the Little Pig Mine. This property, which adjoins the north end of the Silver Creek Mine and the Beaver Mill on the west, is owned by himself and Mr. Oliver Donnais.

Recent reports from the Silver Falls Mine (43 miles from Port Arthur) indicate that ore will be struck soon. The shaft is now down about fifty-two feet and the water fills in so rapidly that an engine is needed to pump it out.

Operations at the Beaver Mills are expected to be begun about the middle of this month. The houses, shops and mills at this mine are very systematically laid out. Mr. White has charge of the mechanical department and Mr. Crow is reputed a thoroughly practical and experienced miner.

A party of prominent miners and capitalists, including Mr. Alex. McEwen and his three sons, Messrs. G. A. Thompson, A. J. Duffield, and T. A. Keefer, received Sir A. T. Galt and a number of British capitalists quite recently at Port Arthur. The object of their visit to the district was ostensibly to re-open the Silver Islet Mines and to organize for a thorough exploration and development of the gold and silver mining region on the North Shore of Lake Superior.

During the past month the Rabbit Mountain Mine was visited by J. H. Burwell, general manager of Mast Buford & Burwell, machinery house; R. B. Nalusha, general solicitor of the St. P., M. & M. road; H. Sahlgaard, real estate dealer, and vice-consul of Sweden and Norway, all of St. Paul, and John Crubach, railway contractor and bridge builder, Rock Island. The party were delighted with their visit and carried away with them a silver bar weighing 37 1/2 lbs., 95 per cent. of which is solid silver. The mine is owned and controlled largely by St. Paul parties, and it is their intention to enlarge the working capacity to a considerable extent. At present they have a shaft about 120 feet down

and have commenced to work on levels and side cuts.

Several complaints are being made by the miners about the bad condition of the roads in the district, which they say prevents anything like a systematic development of their properties. The road on the other side of the Silver Mountain is in a particularly wretched condition, travel being much impeded by large numbers of stumps from two to three feet high. In winter fully three feet of snow will be required to make the road fairly passable. An expenditure of one thousand dollars should be sufficient to make a good winter road here. As matters stand at present the average rate for carrying freight and supplies is about two cents per pound, a heavy tariff very detrimental to the progress of development, and in the interests of the country it is desirable that steps be taken as soon as possible to have these obstructions removed and the road placed in a passable condition.

The following gentlemen constitute the first Board of Directors of the recently organised Thunder Bay Colonization Railway Company: Thomas Marks, merchant; D. F. Burke, capitalist; George T. Marks, merchant; George H. Macdonell, contractor; Thomas S. T. Smellie, physician; W. G. Smith, merchant; Michael Dwyer, contractor; Allen R. Macdonnell, contractor; T. A. Gorham, barrister. Referring to this the *Sentinel* writes:—"It is our pleasant duty to chronicle the arrival at Port Arthur of the first silver brick ever manufactured in this district from Thunder Bay ore. Although, of course, in the past large quantities of barrelled ore as it came from the mine, and concentrates from the various mills, have been shipped. The Rabbit Mountain Mining Company is the first institution to have built a mill which produces silver by amalgamation as well as by concentration. The bar in question weighs about forty-five pounds and it is rendered doubly valuable in the eyes of mining men from the fact that the whole of this has been collected from the tailings which have passed over the ordinary Frue vanners, and the silver of which in the mills heretofore built in the district was also entirely lost to the proprietors. To those unlearned in mines it is hard to understand the value of the product from samples of the concentrates, but the most unlettered in a mining way can readily see and understand its product when of pure silver. The bearing of each of these interesting events have a most important effect on one another. Without the Thunder Bay Colonization Railway the mines cannot be worked to their full extent, nor can they be worked as economically as their most ardent admirers would desire. And without the mines one of the most important factors in the future success of the railroad's traffic returns would be wanting.

From present indications we are happy to say that we are not only likely to have the railway, but that beyond peradventure the mines of the Thunder Bay district will play an important part in furnishing traffic for the new line."

Manitoba.

Work at the Cascade Coal Mines, near Banff, is being vigorously pursued, and the owners will soon place their anthracite coal in the market at Winnipeg. The Canadian Pacific Railway have been using it on some of their engine, running on heavy grades, but their report of the test is not yet available. The Canada Anthracite Coal Company are putting new machinery in place,

and are doing everything in their power to conduce to the full development of their property.

British Columbia.

A number of men are out in the country to the north of Bayne's Sound prospecting for gold.

Mr. Krail, a mining expert, who visited the interior a few months ago, and then went to California, has returned to Victoria. He states that this country is rich in minerals, and will locate permanently here. He is examining a ledge 14 miles from the city and will soon report on its value.

Mr. J. M. Smith, who has recently been engaged in collecting geological specimens for the local government, brought from the Selkirks a number of valuable specimens of mineral ores. Amongst other samples was one thirty pounds in weight taken from the Kerr, Corbin and Kennedy claim near the summit of the Selkirks, about 30 miles east of Farwell. An assay made of this ore went as high as \$700 to the ton. The owners refuse to sell, having means enough of their own to work the lead effectively, and have sent forward a carload of the ore to be smelted at Chicago. Mr. Smith also brings with him samples of gold-bearing free milling ore from the Bonanza King or Bright & Tayford lead in the Big Bend district; and in addition, a specimen of silver ore from a mine at Spellmeheen, about 30 miles from Farwell, which assays \$116 to the ton.

Mr. G. A. Koch, a mining engineer, who has been for some time past testing the value of quartz ledges in the Cariboo district, for the local government, expresses the opinion that gravel mining in this district is virtually worked out. He reports the quartz interests throughout the whole district as good, and gives the following information regarding the mineral wealth and the various gold bearing properties in and around Cariboo.

There is a ledge called the Bonanza upon which the B. C. Mining and Milling Co. have located their claim; and have got a shaft down 100 feet from the surface passing through a vein 23 feet wide. Mr. Dunlevy, of Soda creek, has got engine power on his claim on Island mountain sufficient for 20 stamps, and all the power necessary for the concentration of the ore. The B. C. M. & M. Co. have got machinery for 40 stamps, which was formerly bought for the free milling process. Mr. Koch has made no less than 100 assays of ore taken from lodes in the Cariboo district, and in his report to the government states, that the ores average from \$17.50 to \$20 per ton. The cost of mining and milling these sulphurets ores will not exceed that of mining and milling free gold ores, because the cost will more than offset the cost of the closer milling necessary for sulphurets, so that the percentage is in favor of mining the latter class of ore. Aside from these considerations, free milling mines are as it were, only of a day, while the sulphurets are well known to be continuous. There is, for instance, the Providence mine in Nevada county, and the Dr. Zealy mine in Calaveras county, California, which have been working for many years, paying well, though the ore of the latter mine only averages \$6.50 per ton. From the Treadwell mine (Douglas Island) owned by Senator J. P. Jones and others, a parlor test was sent to San Francisco which returned \$7 to the ton, which was sufficient to convince them that they could make a perfect success. The first mill forwarded was a five stamp on

and its workings confirmed the first test. Then they despatched a 120-stamp mill which is now in full blast, producing a proportionate yield. It is moreover said that another mill of the same capacity will shortly be likewise set at work there. Mr. Koch has assayed over \$600 to the ton from the ore of Island Mountain, made, not from selected samples but from extremely rich sulphurets which exist all through the ore, while again, sulphurets can easily be found that are very poor. The average of the sulphurets of this province, he says, are far richer than those of California. In one instance out of two pounds of sulphuret Mr. Koch took out gold amounting to four thousand dollars per ton, which must not however, be confounded with the average result. There are no means of determining where these rich spots occur, they are so minute and so generally distributed through the veins. He considers that the veins will prove to be permanent and that this province is destined to become a great gold mining country. The only question is that of freight and duties, as it is an impossibility for mining machinery to be made at Montreal until they have had experience: consequently, the machinery will have to be imported from San Francisco.

Mr. Koch has shipped a box of samples of these ores to the Toronto exhibition, and will take with him to San Francisco, a similar lot of samples for exhibition to mining men. The formation of the country, he declares, to be identical with that of California—slate, granite, porphyry, etc.—but with richer sulphurets.

El Callao, the great Venezuelan gold mine, produced and sent to England \$293,000 for July, out of which a dividend of \$6.20 per share was paid, aggregating \$257,600.

We are informed that operations at the Wright silver mine, near Lake Temiscamingue, are being vigorously pushed. An expensive smelter has been completed, and the exportation of quartz has been rendered unnecessary in future.

MINING REGULATIONS

To Govern the Disposal of

Mineral Lands other than Coal Lands.

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labour during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

Iron—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, lench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES, AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, &c., &c.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

A. M. BURGESS,

Deputy Minister of the Interior.

THE INTERCOLONIAL RAILWAY OF CANADA.

and Freight Route,

BETWEEN

CANADA AND GREAT BRITAIN,

AND

direct route between the West and all points on the Lower St. Lawrence and Baie des Chaleurs, also New Brunswick, Nova Scotia, Prince Edward Island, Cape Breton, Newfoundland, Bermuda and Jamaica.

New and elegant Pullman Buffet Sleeping and day cars run on through Express trains.

Passengers for Great Britain or the Continent, by leaving Toronto at 8.30 A.M. Thursday, will join Mail Steamer at Halifax A.M. Saturday.

Superior Elevator, Warehouse and Dock accommodation at Halifax for shipment of grain and general merchandise.

Years of experience have proved the Intercolonial in connection with Steamship lines to and from London, Liverpool and Glasgow to Halifax, to be the quickest freight route between Canada and Great Britain.

Information as to Passenger and Freight rates can be had on application to

E. KING,

Ticket Agent,

FOR SALE,

White Marble Quarry on Calumet
Island.

At this quarry there is an inexhaustible supply of most beautiful white marble. Samples to be seen and information obtained at the office of the MINING REVIEW.

DEPARTMENT OF INLAND REVENUE.

AN ACT RESPECTING AGRICULTURAL FERTILIZERS.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1ST of JANUARY, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contain ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and a sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with,—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein,—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected and which does not contain the percentage of constituents mentioned in the next preceding section,—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars: Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "an Act to prevent fraud in the manufacture and sale of agricultural fertilizers", is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office on 11 noon on Monday, the 1st day of November next, for four timber berths of ten square miles each, more or less, numbered respectively 4, 5, 8 and 9, situated on Kicking Horse River, and Otter Tail Creek, a tributary of the Kicking Horse River, near Field and Otter Tail Stations, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position, approximately, of these berths, together with the conditions on which they will be licensed, may be obtained at this Department or at the Crown Timber Offices, Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

A. M. BURGESS,
Deputy of the
Minister of the Interior.

Department of the Interior,
Ottawa, 14th August, 1886.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office up to noon on Wednesday, the 1st day of December next, for three timber berths of fifty square miles each, more or less, numbered respectively 16, 17 and 18, situated on the west side of the Columbia River, near Golden City Station, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position, approximately, of these berths, together with the conditions upon which they will be licensed, and the forms of tender therefor, may be obtained at this Department or at the Crown Timber Offices at Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

MAIL CONTRACT.

SEALED TENDERS, addressed to the Postmaster General will be received at Ottawa until noon on FRIDAY, 17th December, 1886, for the conveyance of Her Majesty's Mails, on a proposed Contract for four years, three times per week each way, between ASHTON and PROSPECT, from the 1st January next.

Printed notices containing further information as to conditions of proposed Contract may be seen and blank forms of Tender may be obtained at the Post Offices of Ashton, Munster, Dwyer Hill and Prospect, and at this office.

T. P. FRENCH,

Post Office Inspector.

Post Office Inspector's Office,
Ottawa, 23rd Oct., 1886.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned will be received at this Office until FRIDAY, the 19th instant, for the Clearing and Removal of Snow, etc., from the Public Buildings, Ottawa; and also for the Removal of Snow, etc., from the roofs of buildings, out-buildings, walks, avenues or roads, etc., at Rideau Hall.

Forms of Tender and Specifications can be had at this office, where all necessary information can be obtained.

Separate Tenders will be required for each work, and must be endorsed, "Tender for Removal of Snow, Public Buildings," and "Removal of Snow, Rideau Hall," respectively.

Each tender must be accompanied by an accepted bank cheque made payable to the order of the Honorable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party decline to enter into a contract when called upon to do so, or if he fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department will not be bound to accept the lowest or any tender.

By order,

A. GOBEIL,
Secretary

Department of Public Works,
Ottawa, 12th Nov., 1886.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Many of our readers will regret to learn of the death of Mr. James W. Lynch, superintendent of the Derry Phosphate Mines, near Buckingham, Que. The deceased gentleman, who was favorably regarded in mining circles, passed away at Derry, on Thursday, 25th November, from an attack of inflammation of the lungs.

We learn that Mr. E. Gilpin, Inspector of Mines, succeeds the late Mr. John Kelly as Deputy Commissioner of Mines for the Province of Nova Scotia. The new appointment, and the amalgamation of the two offices thus provided, is very favorably received in mining circles throughout the province.

At the meeting of the Iron and Steel Institute, held last month in London, Eng., it was stated in one of the papers read, that a small amount of chromium added to steel renders that metal much harder and improves it for a variety of purposes. If this important fact be universally recognised it will undoubtedly create an increased demand for chromic iron, of which, as our readers know, there are large deposits in the Province of Quebec. Several large blocks of this metal were on exhibition at the Mineral Court of the Colonial and Indian Exhibition.

Messrs. Foster and Gregory, the gentlemen appointed by the Royal Commission to report on the minerals and rocks shewn at the Colonial Exhibition, have completed their examination of the Canadian exhibit. Mr. Foster, who is Her Majesty's inspector of mines for North Wales, reports particularly on the ores, building stones, and other

minerals of economic importance, and we learn that he expresses himself much pleased with the extent and excellence of the collection brought together by our geological survey. Particular mention is made of the large series of silver ores from the Port Arthur district, many of which are very rich, and he expresses the opinion that as that country is opened up, it will become one of the most important mining districts in the Dominion.

It will be remembered that several specimens of chromic Iron, from the Canadian Mineral Court, at the Colonial Exhibition, were recently tested by an English firm with a view to importation. The report on these samples, says the *Canadian Gazette*, "shows that some of the ore is sufficiently rich to suit the requirements of manufacturers in Great Britain, while in the case of other samples it is expected that either by a process of careful selection, or by striking new ground, an ore may be obtained of sufficient richness to be profitably exported. The chromic iron ore occurs in the same districts as the asbestos, which of late years has been so extensively mined. The Quebec Central railway has recently made the deposits much more accessible than formerly. It may be remembered that many years ago a trial shipment, consisting of ten tons of the ore, was made to England, but it was then found to be too poor in chromic oxide to be profitably handled."

The action of coal dust in bringing about colliery explosions, was very clearly explained by Herr Nasse in his address to a recent meeting of German mining engineers at Düsseldorf. From experiments it appears that risk of explosion depends upon four circumstances and conditions, each of which affect the explosiveness of the air in a large degree. These are (1) the quantity and degree of firmness of the dust, circumstances that depend upon the hardness and the structure of the coal; (2) its chemical constitution; (3) the quantity of carbonated hydrogen present; and (4) the degree of moisture in the dust. The last is a matter of great importance, and demands careful attention. It is a variable condition in the same mine; for dust may be very dry in one part of the workings and saturated with moisture in another. Also, the moisture contained in the coal-seam may be much less in one mine, or in one locality, than in another; so that great variations in the dryness of the dust at the working faces may be observed. Generally, the seams that do not reach the surface are much drier than those that crop out. The former usually contain about 4 per cent. of water; the latter, from 9 to 15 per cent. Herr Nasse believes watering to be desirable, and where shot-firing is carried on, necessary. But he admits that practical difficulties have hitherto stopped the way against a general adoption of this precautionary measure. He thinks that the subject should receive more attention from mining engineers.

The following interesting item, on the state of the Nova Scotian coal trade, appears

in a recent issue of the *Canadian Trade Review*. "When we had a reciprocity treaty with the United States, the Americans were the principal purchasers of Nova Scotia coal. In 1865 and 1866, out of an average of 595,000 tons mined, about three-fourths of the entire product went across the border. After the abrogation of the treaty, the American import duty upon bituminous coal of course interfered with the sales to the United States, and gradually those sales have decreased, until last year the Americans took but 34,000 tons, only a thirty-eighth part of the entire product. We then protected our coal miners, and the manufacturing industries. The first movement gave the miners an extended home market, the second increased the consumption and consequently the demand for coal. Now, instead of mining only 595,000 tons annually as in 1886, or 700,000 tons as between 1871 and 1880, the Nova Scotia output had reached 1,352,000 tons, at which it stood in the year 1885. Of this quantity Nova Scotia, owing in part to the increased demand for manufacturing purposes, used 450,000 tons, while New Brunswick took 150,000. The Upper Provinces took 493,000, and the remainder was taken by Prince Edward Island, Newfoundland and the West Indies. The total sales of Nova Scotia coal in 1879 reached 688,624 tons. The total sales in 1885 reached 1,250,000, and the output 1,350,000. Thus the business has doubled since 1879. The total sales to Ontario and Quebec in 1881, two years after the introduction of the National Policy, were 268,000 tons. The total sales to the same provinces in 1885 were 493,000 tons, an increase of not quite one hundred per cent. in five years.

At the present time, writes the *Chicago Mining Review*, there is occasional enquiry concerning the probable exhaustion of our coal, oil and gas fields. The assumption generally being that these supplies were created ages ago, and stored up in reservoirs, in which they are now discovered to meet the requirements of the present time. Some years ago the problem of the future supply of coal assumed large proportions and was considered with much anxiety. The discovery of petroleum and its adaptation to use as fuel, removed and destroyed much of the interest connected with the discussion of the question of supply. As attention was turned to the supply of oil, and its outlines were beginning to be definitely established in the minds of speculative investigators, the value and importance of the wide-spread discoveries of natural gas still farther removed the date of the exhaustion of our fuel supply. At the present time there is much difference of opinion concerning the permanence of the supply of natural gas; many holding that it has been collected in reservoirs, which, when depleted can never be refilled, hence predict a short season of spasmodic activity in the life of this new agent, which is already becoming an important factor in the industrial history and advancement of the present time. As we have stated, much of the difficulty and confusion comes from a lack of definite

knowledge concerning the productive causes or the creative forces which, by their action, gave these important productions as a result and until this can be more positively established and is better understood, all discussions and conclusions in regard to the magnitude or permanence of the supply must be problematical and unsatisfactory. Our own opinion, in regard to this matter, is that the creative forces of nature are ever present and ever active; that the creative period is never ending, and wherever favorable circumstances exist the union of chemical elements, according to established laws and affinities, will unite and produce their diversified product and results.

"Since the days of '49,'" writes an authority, "prospectors have mistaken mica, or 'fool's gold,' for gold itself. Mica, in nature, is very abundant; it is met with in every camp; we are brought face to face with it in every mountain range as its forms are of three constituents of which granite is composed (mica, quartz and felspar). It is also a prominent constituent in granite, gneiss, and mica-schist. We find it again in our soil, formed from the disintegration of the above named rocks. From a mineralogical standpoint, common mica is called 'botite,' which is a magnesia-iron mica, part of the alumina being replaced by sesquioxide of iron, and protoxide of iron and magnesia existing among the protoxide bases. Black is the prevailing color, but brown, green, yellow to white also occur. Prisms, commonly tabular; often in disseminated scales, sometimes in massive aggregations of cleavable scales. The hardness is 2.5 to 3. Now note the specific gravity, which ranges between 2.7 and 3.1; while that of gold raises from 15.5 to 19.5; according to its purity. In countries where mica-schist abounds, yellow mica in the sand is very abundant, and often deceives the eye of the prospector in his search for gold. This silvery and golden mica in scales is the 'cat-silver' and 'cat-gold' of Mediaeval Europe. Others mistake iron and copper pyrites for gold, and arsenical pyrites are mistaken for silver; this last, in fact, is a very common mistake, even in old camps. Gold is sometimes found in a finely divided condition in pyrites, but vast masses, or perhaps it would be better to say mountains, of it in California and Colorado do not carry a trace of gold. Pyrite or bi-sulphuret of iron is very brittle; its hardness is about 6.5, while that of gold is 2.5. It occurs commonly in cubes, usually of a brass color. The cubic faces are often striated, with striations of adjoining faces at right angles. Chalcopyrite is a double sulphurate of copper and iron of a brass-yellow color and metallic lustre; on exposure to moist air it becomes iridescent on its surface. It is easily scratched with a knife, giving a greenish black powder. It is the principal ore of copper at the Cornwall mines. Arsenopyrite or mispickel has a hardness of 5.6, and is very brittle; of a metallic lustre and a silvery-white to steel gray color. This metal occurs in small particles in the partly oxidized ores of this camp, and is very often mistaken for silver. Pyrites, being brittle, are readily reduced to

powder before the blow of the hammer, while gold and silver in their native state will flatten."

As much as the miner may oppose the scientist and the school-taught expert, there is much reason for a larger increase in knowledge in every branch of mineralogy and metallurgy. The history of the loss and waste in connection with mining operations and ore treatment during the past few years, when its immense magnitude is fully comprehended, will not prove to be a very strong support in favor of the methods that have prevailed, or the management and skill of those directing them. Those who more fully comprehend the question, clearly understand that a union of practical and theoretical knowledge is most to be desired, and that neither the theorist and student, or the practical miner or mill man, can afford to ignore the other. Every increment of knowledge, from whatever source, or however gained, is an additional element of power to be used in the accomplishment of any purpose. The wider the range of information, the more comprehensive the understanding, the deeper the insight and investigation, so much better fitted and more valuable is the possessor to accomplish the best results in the most economical manner. It is more than probable that some mistakes and some losses have accrued from the inexperience of scientists and experts, but the mining territory from Alaska to Mexico is covered with the monuments of inexperience and ignorance, erected at a vast expenditure of time and money, by men claiming to be practical. Practically, notwithstanding the wonderful results, the mining territory has been one vast scene of costly experiments; and to-day even the present methods, as great as is their improvement over those of the past, are by no means creditable to the intelligence and advancement of this century, as shown in the activities of every other industry. We stand, as yet, upon the threshold of improvement in this direction, where such methods and appliances prevail that would ruin any other business not so prolific in resources. The bleaching bones of thousands of enterprises lost in this desolate desert, and the stagnation that hangs like a gloom over so many promising localities, the indifference of capital to the most alluring stories of glittering wealth, the languishing camps that appeal in vain for assistance to open the treasure-houses within their limits, all show the uselessness of attempting to proceed by old methods; and the imperative necessity for a wiser management, a more comprehensive knowledge, and the inauguration of new methods in developing the vast mineral resources of our country; which will some day, when these questions are practically met, give results that will astonish and outshine the most flattering and wonderful statements yet recorded in the history of this great industry.—*Chicago Mining Review.*

Miners returning from the Lorne Creek mines, B.C., report a very unfavorable season there owing to the continued high water.

Phosphate Shipments from Montreal for Season of 1886.

Iron Among the Ancients.

Iron was first used in Western Asia, the birthplace of the human race, and in the northern parts of Africa, which are near to Asia. The Egyptians, whose existence as a nation probably dates from the second generation after Noah, and whose civilization is the most ancient of which we have any knowledge, were at an early period familiar with the use and manufacture of iron. Iron tools are mentioned by Herodotus as having been used in the construction of the pyramids. In the sepulchres at Thebes and Memphis cities of such great antiquity that their origin is lost, butchers are represented as using tools which antiquarians decide to have been made of iron and steel. Iron sickles are also pictured in the tombs at Memphis, and at Thebes various articles of iron have been found which are preserved by the Historical Society at New York, and are probably three thousand years old. Thothmes the First, who is supposed to have reigned about seventeen centuries before Christ, is said in a long inscription at Karnak, to have received from the chiefs, tributary kings, or all of

sovereigns of lower Egypt, presents of silver and gold, "bars of wrought metal and vessels of copper, and of bronze, and of iron." An expedition which the same king sent against Chadasha, returned bringing among the spoil "iron of the mountains, 40 cubes." Belzoni found an iron sickle under the feet of one of the sphinxes at Karnak, which is supposed to have been placed there at least six hundred years before Christ. A piece of iron was taken from an inner joint of the great pyramid at Gizch in 1837. Both of these relics are in the British Museum. The reference to iron in Deuteronomy, iv, 20, apparently indicates that in the time of Moses, the Egyptians were engaged in its manufacture, and that the Israelites, if they did not make iron for their taskmasters, were, at least, familiar with the art of manufacturing it; "but the Lord hath taken you, and brought you forth out of the iron furnace, even out of Egypt." This expression is repeated in 1st Kings, viii, 51. A small piece of very pure iron was found under the obelisk which was removed in 1880, from Alexandria to New York. The country which lies to the south of Egypt is supposed to have produced iron in large quantities in prehistoric times. Iron was known to the Chaldeans, Babylonians, and the Assyrians, who were contemporaries of the early Egyptians. Some writers suppose that the Egyptians derived their supply of iron principally from these Asiatic neighbors, and from the Arabians. Among the articles discovered by Layard, at Nineveh, were iron scales of armour from two to three inches in length. He also found a perfect helmet of iron, inlaid with copper bands. The Old Testament teems with incidents in which iron is mentioned. In the wanderings of the children of Israel, iron is frequently mentioned. When they smote the King of Bashan, they found him within an iron bedstead. Canaan, the land of promise, is described in Deuteronomy as "a land whose stones are iron." The Medes and Persians, India, and China, and other eastern countries appear to have been acquainted with its manufacture from a very early period. It is worthy of mention that the mythologies of both Greece and Rome attributed the invention of the art of manufacturing iron, to the gods, a fact which of itself may be regarded as establishing the great antiquity of the art in both centuries. Homer, who is supposed to have lived about 850 years before the Christian era, and, therefore, before the era of authentic Grecian history, makes frequent mention of it in his poems. Some of the swords and javelins of the Romans were made of iron and steel in fourth century before the Christian era, but their agricultural implements, were made of iron at an earlier period. The Romans used a battering ram, which had a head of iron, at the siege of Syracuse, in the year 213 before Christ. In the Acts of the Apostles, a statement is made which indicates that iron was used at this period for architectural purposes, "when they were past the first and the second ward they came unto the iron gate that leadeth into the city." Pliny says that iron ores are to be found almost everywhere. Iron has also been found in the ruins of Pompeii, about the time the Coliseum was built.

New Jersey Cedar Mines.

Among the strange productions of Cape May are the "Cedar Mines"—swamps of dark miry stuff, in which are buried immense trees of White Cedar, *Cyprinus Thyoides* of the botanists. These mines contain enormous trees buried to a depth varying from three to 10 feet. The logs lie one across the other, and there is abundant evi-

dence to show that they are the growth of different successive forests. Indeed in these very swamps forests of the same trees are now growing. The miners become very skillful at their work. An iron rod is thrust into the soft mud, over which often the water lies. In striking a buried tree, the workman will by several soundings, at last tell how it lies, which is its root end, and how thick it is. He then manages to get a chip off the tree, and by its smell determines at once whether it is worth the labor of mining—that is, the workman will tell unerringly whether the tree be a *windfall* or a *breakdown*. If a breakdown, it was so because it was decayed when standing; if a windfall, the tree fell while sound, and has been preserved ever since by the antiseptic nature of the peat marsh in which it was buried. The soft earth is then removed. This makes a pit in the swamps. Into this the water soon flows and fills up. The saw is now introduced, and at regular intervals a cut is made through the tree. It is curious that the log of a sound tree will sure to turn over when it floats up, the lower side thus becomes uppermost. Trees in this way are sometimes obtained, which yield 10,000 shingles worth \$20 per thousand, thus one tree will yield \$200. The age of many such trees, as the season rings have been counted, has been made out to be from ten to twelve hundred years, and even more. A layer of such trees is often found covered by another layer, and these again by another, and even a third, while even living trees may still be growing over all. It is evident, indeed, that New Jersey has experienced what the geologists call "osilations." Cape May contains abundant evidence of having been lifted out of a modern sea. The recent oyster and clam are found in natural beds, just as they did in the ocean, but now in positions many feet higher than the contiguous oyster beds; while buried trees exist at depths lower than the beds of mollusks.

PROSPECTING.

Indications that will Facilitate the Search for Minerals.

(SELECTED.)

The search for minerals in any given district should not be undertaken unless there is some previous indication as a reason for it; because, save the most ordinary building materials, the mineral substances to which the art of mining is applied are sparingly distributed in nature; and in any given point of the earth's surface we are authorized to suppose *a priori* that these substances do not exist.

More or less proximate indications of their existence may be deduced:

1st. From a knowledge of the geological structure of the country.

2nd. From the presence at the surface of the ground of fragments of veinstone or of ore.

3rd. From the presence of the outcrops.

It is advisable to give a few details on the value which should be attached to each of those indications.

The geological structure of the ground sometimes furnishes *positive*, sometimes *negative* indications.

It is evident, for instance, that the existence of an igneous rock, such as granite, shuts out the possibility of there being coal *at the same point*; but this conclusion only holds good *for the very point under consideration*; and it is known, for instance, that a large number of more or less developed coal mines in France are scattered over the primitive central plateau, and thus rest either upon granite itself or upon such ancient

rocks as gneiss or mica-schist. As an example of a *positive indication* it may be said, on the contrary, the presence of the *Coal Measures, properly so-called*, may fairly lead us to suppose that coal is present also. It is rare, in fact, unless in the case of a mere insignificant patch of the rocks, that the coal measures do not contain some workable seam of coal, and we have seen from the examples of the Belgian coalfields that they sometimes contain a very large number. It may also be said that the existence of Permian rocks may lead us to conjecture the presence of copper; that of the Trias, and more especially of the variegated Marls, the presence of rock salt (at all events in the north east of France); that of the supraliassic Marls the proximity of iron ore.

The presence at the surface of the ground of fragments of useful substances (shoad-stones), or even of sterile, substances known to be often associated with the first, is an indication which deserves to attract attention. In prospecting a country, an examination should be made of all denuded parts, escarpments, sides of valleys, etc., and particularly of ravines and beds of the different water courses. Standing in the bed of a torrent we find everywhere, in some measure, a collection of mineralogical specimens derived from all the region higher up. Each mineral species has its own value from the point of view under consideration. Among rocks consisting of mica-schist, for instance, we shall attach very little importance to fragments of quartz with a simply resinous or even saccharine fracture, as this substance frequently occurs interposed in reiform lumps between the folia of the schist. Well crystallised quartz will deserve more attention. Substances that are foreign to the composition of the rock and known to be pretty commonly veinstones of lodes, such as calc-spar, fluor spar, harytes, etc., will deserve still more attention. The same thing will be the case *à fortiori*, if spots of pyrites, or galena, or any traces of a green coloring due to the decomposition of copper ore, etc., are found on breaking these fragments.

In carrying out observations of this kind it is necessary to ascend the beds of the torrents step by step, examining the sand and pebbles carefully and minutely in order to ascertain how high up the fragments which awakened attention by their special nature, are found, and thus to discover the point whence they are derived. An idea of the distance of this point may be formed from the more or less rounded shape of the fragments, due consideration being paid to their hardness. When this point has been discovered it will only remain to examine whether the substances noticed have a purely adventitious character of the rock, or whether they belong to a deposit apparently of some extent. This verification is quite essential, for the first case is perhaps that which presents itself most frequently to the observer.

Mineral springs furnish us with indications with regard to soluble substances, analogous to those obtained from fragments of rock concerning insoluble substances. It is thus that brine springs, or springs charged with chloride of sodium, have led to the discovery in the east of France, and especially in the department of Mewithe, of thick beds of rock salt, which are being actively worked at the present day.

If by direct observation, or by proceeding in the manner described in the preceeding paragraphs, we have ascertained the presence of an outcrop, this outcrop should be made the subject of a special examination. As the lode is of a *different nature* to the enclosing rocks and has been exposed to the *action of the same atmospheric agents*, it will not have resisted in the

same way. It will often appear at the surface, either as a hollow or in relief, according as its hardness is greater or less, than that of the enclosing rocks. It is in this manner that hard quartz ore lodes are seen standing out above the surface of the ground in the form of prominent walls, many feet high, running sometimes for a distance of several hundred yards. These outcrops are a certain indication of the presence of a lode; but as a rule they do not give any information about its richness, since the metallic substances have generally been oxidized and removed in the state of soluble salts, often leaving behind nothing but an ochreous precipitate, from the amount of which, in certain cases, may be inferred the quantity of certain metallic sulphides, such as iron or copper pyrites, which the deposit originally contained. This ochreous precipitate itself is often absent, and the outcrop only shows by a slight accidental discoloration any sign of its original richness in ore. Even if an outcrop contains no ore whatever, it is still worthy of investigation if it exhibits a certain continuous character. Therefore, the first care, after having hit upon some point of an outcrop, should be to make sure whether this continuity exists. In case it is not apparent at the surface, a few pits may be sunk to endeavor to ascertain the strike and dip of the deposit and to infer from these, allowing for the outline of the ground, the approximate position of the line of outcrop. This line should be staked out, and efforts should be made to discover other points of the outcrop by digging trenches at intervals at right angles to its presumed strike, and then down till rock in place is met with. When at least three points of the outcrop, not very far apart, and situated at different levels, have been determined in this way, a plane passing through these three points, in case of a lode or bed, may be taken provisionally, on account of possible disturbances of the deposit between these three points, as representing the position of the deposit of the bosom of the earth; it will also serve as a basis for settling upon the best manner of exploring the deposit in depth. If it is a massive deposit with two comparable horizontal dimensions the preliminary excavations should be carried on so as to circumscribe it in every way.

BOOK NOTICES.

The veteran chemist and mineralogist, Dr. T. Sterry Hunt, presents as Chapter VIII, of his *Mineral Physiology and Physiography* (a second series of "Chemical and Geological Essays," a treatise on *A Natural System of Mineralogy, with a Classification of Native Silicates*. This treatise has been published in full in the *Transactions* of the Royal Society of Canada, and in abstracts more or less extended in other places. We cannot undertake, within the limits of an article, to give it an adequate critical examination. The best that we can hope to do is to impart to our readers a general notion of its contents.

The essay is in three parts. In the first, which is an historical introduction, the author outlines the systems of classification in the mineral kingdom proposed by Werner, Mohs, Dana, Berzelius, Rammelsberg, and others, and shows that the "natural history" systems of Werner and Mohs (followed with more or less modification by Haidinger, Jameson, Shepard, and, in his earlier editions, Dana) were founded on external characters, such as hardness, specific gravity,

and crystalline form, independent of composition, as revealed by chemical analysis. Students of mineralogy under the eminent teachers of the last generation will remember that they taught determinative mineralogy without recourse to chemistry, and even looked upon the blow-pipe as almost an evil—a thing which the metallurgist might need, but the mineralogist had better do without, save in the last resort. We can bear witness to such a feeling in the case of the venerable Breithaupt, the successor of Mohs at Freiberg; and under his successor, Weisbach, it has not ceased to exist.

Indeed, for certain purposes of instruction, it is the right feeling. Determinative mineralogy should be so taught that the student may become able, in the great majority of instances, to recognise minerals from their physical characters. And since the practical field-mineralogist has more to do with determinative than with analytic mineralogy, it is natural that he should retain the tendency received at school, and that he should become more familiar with hardness, streak, and crystalline than with molecular equivalents. Moreover, the mineralogist is usually a collector, and, as Dr. Hunt acutely remarks, the divorce between physical and chemical characters maintained in the study of mineral species by Werner, Mohs, and their followers, produced a system available for the purposes of determination without the destruction of the individual specimen. The artificial system of Linnæus in botany possessed the same advantage; and that it is for many purposes a practical advantage, the tenacious life of that system, in spite of its scientific absurdity, bears witness. The same will probably continue to be the case with the mineralogical systems which science has more or less outgrown. They will survive in tables and in practice, long after they are shown to be less truly natural than those which take into account the chemical analysis as of paramount importance.

There is, in fact, a general consent among mineralogists that the chemical system, proposed by Berzelius, and perfected by Rammelsberg, Naumann, Dana, and others, presents the truly natural classification. Hardness, specific gravity, crystalline form, optical characters, etc., are rated as secondary in value, and important chiefly as means of determination. But this is to go to the other extreme. A truly natural system should be based on both physical and chemical grounds—if such a thing be possible; and possible it can become only when, to use Dr. Hunt's words, "inherent and necessary relations between the physical characters and the chemical constitution of inorganic bodies" are made known. That such relations exist, our author declares; and in this essay he seeks to establish at least some of them.

The second part of the paper before us reviews at some length the author's progressive treatment of this subject since 1853, when he first declared the possibility of a physico-chemical classification. We shall not follow this review in detail, but content ourselves with quoting from a paper published in 1867, the following admirable statement of guiding principles:

"In approaching this great problem of classification, we have to examine, first, the physical conditions and relations of each species, considered with relation to gravity, cohesion, light, heat, electricity, and magnetism; secondly, the chemical history of the species, in which are to be considered its nature, as elemental or compound, its chemical relation to other species, and these relations as modified by physical conditions and forces. The quantitative relation of one mineral (chemical) species to another is its equivalent weight, and the chemical species, until it

attains to individuality in the crystal, is essentially quantitative. It is from all the above data, which would include the whole physical and chemical history of inorganic bodies, that a natural system of mineralogical classification is to be built up. . . . The variable relations to space of the empirical equivalents of non-gaseous species, or, in other words, the varying equivalent volumes (obtained by dividing their empirical equivalent weights by their specific gravity) show that there exist in different species very unlike degrees of condensation. At the same time, we are led to the conclusion that the molecular constitution of gems, spars, and ores is such that those bodies must be represented by formulas not less complex, and with equivalent weights far more elevated, than those usually assigned to the polycyanides, the alkaloids, and the proximate principles of plants."

Following the line thus indicated, Dr. Hunt began by seeking to find in the realm of inorganic chemistry the laws progressive or homologous series and polymerism, already recognized in the chemistry of the hydrocarbons. Already in 1853, he had suggested that "all species crystallizing in the same shape have the same equivalent volume, so that their equivalent weights (as in the case of vapors) are directly as their densities, and the equivalents of similar species are as much more elevated than those of the carbon series as the specific gravities are higher." And this suggestion he had illustrated with instances drawn chiefly from the carbonate spars and the polysilicates. In these and later essays in the same direction, Dr. Hunt indicated, as the principal evidence and measure of the connection between the chemical and the physical characters of species, *the relation of equivalent weight to specific gravity*.

The complete statement of the principles adopted as a basis of classification is now given substantially as follows:

1. The extension to all mineral compounds of the conception of high equivalent or molecular weights like those of the carbon series in so-called organic chemistry.
2. The similar extension of the laws of progressive or homologous series.
3. The attribution of minor variations in the chemical composition of a mineral species not only to its polybasic character (that is, to the replacement of one base by another in varying degrees), but also in certain cases to indefinite admixtures of homœomorphous species.
4. The assumption that for homœomorphous solids, and probably for all solids, the molecular volumes are identical; and the attempt to fix the molecular weights of such compounds as the polysilicates and polycarbonates from their densities, as compared with those of species the minimum molecular weights of which are otherwise determined.
5. The adoption of atomic formulas to represent the composition of mineral species, and the comparison of the volumes of complex species by means of numbers deduced from these formulas. The term *atomic* here used, is distinguished from *molecular*; and Dr. Hunt's atomic weights are derived from the ordinary chemical equivalents, or molecular weights, by multiplying the latter by the numbers representing the atomicities of the respective elements. His symbols are distinguished by the use of small letters instead of capitals. Thus, for the monad elements like sodium, chlorine, and fluorine, the atomic symbols represent the same numbers as the received molecular weights: Na = na = 23; Cl = cl = 35.5; etc. For dyad elements, like oxygen, calcium, and ferrosium (that is, iron in ferrous salts), the molecular weights are divided by 2

O = 16, o = 8. Ca = 40, ca = 20; Fe = 56, fe = 28. For triads, like aluminium, boron, and ferricum (iron in ferric salts), the divisor is 3: Al = 27, al = 9; B = 11, b = 3.66; Fe = 56, fi = 18.66. For tetrads, like silicon and titanium, the divisor is 4: Si = 28, si = 7; Ti = 50, ti = 12.5. Finally, the pentad, niobium, requires 5 as divisor: Nb = 94, nb = 18.8.

Employing these weights, Dr. Hunt translates the empirical formulas of the received notation into atomic formulas, and these formulas he affects with a modulus or multiplier, to represent the law of polymerism. Thus, the formula of lime-magnesia pyroxene given in Dana's text-book is $\text{CaMgSi}_2\text{O}_6$. Calcium, magnesium, and oxygen, being dyads, and silicon a tetrad, the atomic formula for this variety would be $\text{ca}_2\text{mg}_2\text{si}_4\text{o}_{12}$, or, using the symbol *m* to represent the interchangeable metallic elements, $\text{m}_4\text{si}_4\text{o}_{12}$. This is the same in proportion as $\text{m}_2\text{si}_2\text{o}_6$; while, as to the molecular weight of the body as a whole, that is, of the species, it can not be determined from an empirical formula derived solely from chemical analysis. It must be either the weight directly shown by the formula, or some multiple of it; that is all we can say so far. Hence, the general atomic formula for the *molecular weight* of pyroxene is written by Dr. Hunt $n(\text{si}_2\text{m}_2\text{o}_6)$, *n* being the undetermined multiplier. But it is not necessary to know the value of *n* in order to obtain a number representing the volume of the atomic unit. In the case taken for illustration, the empirical atomic formula $\text{si}_2\text{m}_2\text{o}_6$, in which the one atom of *m* is one half *ca* and one half *mg*; we have a total weight of $(2 \times 7) + (0.5 \times 20) + (0.5 \times 12) + 3(8) = 54$. Dividing this by 3, the number of oxygen atoms, we have 18, which represents the weight of the atomic unit of the species, this atomic unit in this case being an oxide. For other combinations than silicates, this atomic weight (the general symbol for which is *P*) is obtained in a slightly different manner, which we will not here stop to consider. *P*, being once obtained, is divided by *D*, the ascertained specific gravity of the species (water = 1.), and the quotient, *V*, is a number representing the volume of the atomic unit.

5. The fifth principle is that, in related and homologous species, the hardness and the chemical indifference are inversely as the value of *V*—or, in other words, that they increase with the condensation which has attended the chemical combination. This, we presume, is a sort of check on the foregoing assumptions and calculations. If the values of *V* are really more closely connected with the characters of hardness and indifference than are the values of *D*; that is to say, if, by manipulation of the atomic formula after Dr. Hunt's fashion, a series of numbers can be obtained which will tell us more, or tell it more accurately, than the simple series representing specific gravities, then the introduction of chemical elements into the calculation is more or less perfectly vindicated. Otherwise, we might just as well throw it all away (so far as this use is concerned), and content ourselves with the simple old notion that among similar minerals hardness and chemical indifference vary as the specific gravity.

It is difficult to apply a precise test in this case; for we have no numerical measure of chemical indifference, and only a very loose and vague measure of hardness. A casual inspection of Dr. Hunt's tables of the silicates shows that *P* does not vary greatly among nearly allied min-

erals, and hence that $\frac{P}{D}$ varies on the whole inversely as *D*.

The third part of the essay presents a classifi-

cation of silicates. Here, the first division is on chemical lines. According as the minerals contain protoxide bases, sesquioxide bases, or both, the order Silicate is divided into three sub-orders: Protosilicate, Protopersilicate, and Persilicate. An ingenious and forcible argument is offered, to show that this division is really fundamental in nature—that it lies in the the processes of mineral genesis and sub-aërial decay. In each of these sub-orders, five "tribes" are distinguished on physical and chemical grounds, which correspond in a general way, though not precisely, to the classes of spars, gems, and micas established by Mohs, with the addition of a separate class of amorphous or colloid species, and a further division of the spars into hydrous and anhydrous. The five tribes of Dr. Hunt thus become Hydrospathoid, Spathoid, Adamantoid, Phylloid, and Colloid; and the sub-order is indicated by the appropriate prefix. Thus, we have under the Protopersilicates, Hydroprotopersilathoids, Protopersilathoids, etc.; under the Protopersilicates, Hydroprotopersilathoids, Protopersilathoids, etc. The longest of these names are replaced in practice by others, referring to typical species. Thus, the Hydroprotopersilathoids are Zeolitoids, comprising the zeolites which do not contain persalts exclusively. The latter (Perzeolithoids) constitute the Hydropsilathoid tribe of the Persilicate order.

Compared with the reigning system of classification; as found in Dana's text-book, this is apparently more symmetrical, logical, and comprehensive. The fundamental division of the former is based on the presence or absence of combined water; and the next rank of subdivision, namely, into bisilicates, unsilicates, and subsilicates, involves a chemical distinction only—a distinction, moreover, which becomes somewhat hazy among the hydrous silicates, which are divided into a "general" section, a "zeolite" section, and a "margarophylite" section. Of course, minerals of very different physical characters are thrown together under this purely chemical classification.

Another scientific advantage in Dr. Hunt's method is, that it is independent of complicated theories as to the arrangement and relations of the atoms or the molecules in chemical combination. The terms *atom* and *molecule*, as employed by him, represent imaginary units, and do not involve the hypothesis of hard particles with void spaces, of bonds and links, to explain chemical affinities. Whether such be or be not the actual constitution of inorganic bodies, is a question which does not affect the relations he has sought to establish.

We have no space to consider his brief suggestion of a scheme covering all mineral species, or his striking discussion of the question of molecular weights. In the latter field, indeed, we feel both least inclined to adopt, and least competent to criticise, his conclusions. Their correctness does not seem to be necessarily implied in his classification of the silicates.—*Engineering and Mining Journal*.

"Mr. Charles Marvin," writes a prominent English authority, "whose name of late years has, by reason of his writings on Russian affairs, become very familiar to the public, sends us a pamphlet, 'The Coming Deluge of Russian Petroleum.' On this occasion Mr. Marvin writes on a commercial subject, and he has put together a number of astounding facts as to the wealth of the petroleum springs of Baku. He tells us at the outset that a single well in Russia yields daily more petroleum than all the other oil wells in the world combined, and there are

25,000 wells in America. Three years since a well was reported at Baku to be spouting 3,400 tons of petroleum daily, and the world wondered; but Mr. Marvin tells us that this autumn one well has been spouting 11,000 tons of petroleum daily. The object of Mr. Marvin is to again call the attention of English capitalists to the rich field for enterprise in the development of these Russian oil wells. Development is hardly the word applicable to the wells, for they have a manner of developing themselves, and inundating the surrounding district with oil. Mr. Marvin told of the vast extent and practically inexhaustible character of the wells some years since, but he complains that British capitalists have not come forward to claim their share of the trade. There are 120 firms at Baku having oil refineries and they produced nearly 120 million gallons of refined petroleum. Eight years ago the output was but one and a quarter million gallons, and this marvellous development is attributed to improved means of transport. Formerly the oil had to be barrelled on the spot. In 1879, a steamer fitted with oil tanks for conveying petroleum in bulk commenced working on the Caspian sea, and now there are upwards of 100 Russian steamers carrying on the trade. Mr. Marvin explains that the Baku crude petroleum yields, but 30 per cent of "lamp oil," as compared with 70 per cent. in America, but 60 per cent. of the residue called *astalki* can be treated to yield valuable products particularly for lubricating purposes. One well-known London firm Sir Charles Price & Co., is regularly receiving large shipments of this residue, and it is asserted that lubricating oil made from it is of extraordinary quality. As the price at Baku ranges from 4d. to 1s. 4d. per ton, there must be plenty of money to be made in this branch of the trade. Nearly 3½ million gallons of lubricating oil were sent from Baku up the Volga last year, and upwards of 2½ million gallons were despatched by the Batoum railway. Owing to the low cost of the oil refuse it is being largely used for steam generation in the steamers running from Batoum to Odessa; the Russian fleet on the Caspian has used nothing else since 1874; and the Black Sea Company, owning 76 steamships, will shortly adopt it exclusively. Messrs. Rothchild are largely interested in the trade, and to facilitate transport have placed 250 tank cars on the Transcaucasian Railway. By this line 80,000 tons of managene ore were carried from the Caucasus last year. Mr. Marvin proves that the great need of the district is a cheap means of bringing the oil to a shipping port. Messrs. Rothschild have applied for a concession to construct a pipe line from Baku to Poti or Batoum, six hundred miles; but they have been refused because they are working oil refineries, and the Russian government stipulates that the pipe line shall be controlled by a company not interested in the advancement of any particular refinery. The estimated cost of the pipe line is £2,000,000, and already at least one English firm has sent representatives to Baku and Batoum to investigate the scheme, and examine into the work necessary. Two of the directors of Messrs. John Russell and Co., limited, of Walsall and Wednesbury, were out last year, and Mr. Marvin states that a representative of the firm is now on the spot. Quite apart from the illuminating oils, the Baku oil wells seem likely to have an important bearing on the "liquid fuel" question which is now being discussed by some of our scientific societies. As to the permanency of the Caucasian oil wells. Mr. Marvin says that the oil bearing character of the district was known 2,500 years ago, and oil has probably been flowing on uninterruptedly ever since.

Mineral Products of the United States.

Advance sheets of the report of the United States Geological Survey have just been received, which show the total production of minerals in this country during 1885, as compared with previous years. Of the metallic minerals produced pig iron appears to have been the most valuable in total production, and platinum appears to have been the scarcest. The total production of pig iron in 1885 was 4,045,525 long tons, valued at \$64,712,400 against 4,097,863 tons valued at \$73,761,624 in 1884. The total consumption of iron ore was placed at 7,990,786 tons, of which only 390,786 tons were imported. Silver was next to iron in total production, being 39,910,279 ounces, of a coining value of \$51,600,000, against 37,774,605 ounces in 1884, valued at \$48,800,000. The total gold production was 1,538,376 ounces, valued at \$31,801,000 against 1,489,949 ounces, valued at \$30,800,000 in 1884. Copper showed a slight increase over the preceding year, as 170,962,617 pounds, valued at \$18,292,999 in New York, were produced in 1885, against 147,805,407 pounds valued at \$18,106,162 in 1884. Lead was produced to the extent of 129,412 short tons, valued at \$10,469,431, against 139,897 tons in 1884, valued at \$10,537,042. The quantity of zinc mined showed an increase, 40,688 short ton, valued at \$3,539,856, being produced in 1885, against 38,544 tons, valued at \$3,422,707 in 1884. The valuations above given for copper, lead and zinc are those current at New York. The quicksilver production was valued at San Francisco at \$979,189, against \$936,327 the year before, and the production was 32,073 flasks, against 31,913 flasks in 1884. The production of nickle was much heavier than in 1884, as 277,904 pounds, valued at \$191,753, were mined in 1885, against 64,550 pounds, valued at \$48,412 in 1884. Crude platinum was produced to the extent of 250 troy ounces, valued at (New York) at \$187, against 150 ounces valued at \$450 in 1884. Aluminum was produced to the amount of 3,400 troy ounces, valued at Philadelphia at \$2,550 against 1,800 ounces, valued at \$1,350 in 1884. Of the non-metallic minerals, coal was the most important production, the yield of all kinds of this fuel being 99,969,216 long tons, valued at \$159,019,596, against 106,906,295 tons, valued at \$143,768,578, in 1884. It will be seen from the above figures that while the total production of coal fell off 7,837,079 tons, the value increased \$15,251,018, showing an average increase in price of 25c per ton. The above figures include the colliery consumption. The bituminous coal produced amounted to 64,840,668 tons, valued at \$82,347,648, against 73,730,539 tons, valued at \$77,417,066, while of anthracite 34,228,548 tons were mined, valued at \$76,671,948 against 33,175,756 tons, valued at \$66,351,512 in 1884. Of petroleum 21,842,041 barrels, valued at \$19,193,694 were produced, against 24,089,758 barrels, valued \$20,476,294 in 1884. Lime was an important production, 40,000,000 barrels, valued at \$20,000,000, being made in 1885, against 37,000,000 barrels, valued at \$18,500,000 in 1884. The salt industry was also an important one, 7,038,653 barrels, valued at \$4,825,345, being made in 1885, against 6,514,937 barrels, valued at \$4,197,734 in 1884. The production of building stone was about the same as in 1884, the total value being \$19,000,000. It is worthy of note that 200 tons of "block tin" ore were mined in 1885 at the Etta mine in Dakota. The total value of all the mineral products of the United States in 1885 was \$428,511,356, against \$413,214,748 in 1884. Of this the value of the metallic products was placed at \$181,589,365,

against \$186,414,074 in 1884, while the non-metallic products were valued at \$239,431,991 in 1885, against \$219,800,674 in 1884.

Dishonesty and incompetency, writes the *Critic*, have done much to throw discredit on mining, and this distrust will hardly be removed until our leading business men take hold of it and give mining the position it deserves. A few of our merchants dabble in mines, but their money is too often invested secretly and through the agency of some "cute" operator, who often is an adept in all the practices that throw discredit on mining. They shut their eyes and open their mouths, and receive their share of the profits, with no desire to know the details of the transaction, which they easily surmise cannot bear an honest investigation. "There is nothing like a mining speculation to bring the dirt out of a man," said a leading barrister of our city, and the remark is unfortunately too true. Men who would shrink from the slightest suspicion of dishonesty in their usual business transactions, seem to think that, like in love and war, all is fair in mining. The manipulator of a clever mining swindle who spends his money freely, and jokes openly at the expense of his dupes, is pronounced "a jolly good fellow," while his victims are condemned for their folly in going into a mining speculation. While swindlers in any other business would be forced into court, the mining swindler generally goes free, and his immunity from punishment encourages scores of imitators, who flood the market with worthless schemes. These men are the curse of honest miners, who see capital enlisted in puffed and worthless mines, while their modest statements of facts are passed over. We would echo and re-echo these sentiments.

MINING NOTES

Nova Scotia.

An interesting exhibit from the recently discovered deposits of copper and iron ore in North Sydney was on view during the last weeks of the Colonial and Indian Exhibition.

From the *Canadian Gazette* we learn that: "A company in England has, within the last few days, made arrangements with the owners of a number of the Nova Scotian gold mines for the purchase of their 'tailings.' These will be concentrated in Nova Scotia to a certain richness and then shipped to England for further treatment. The Company has had a number of essays of the 'tailings' made, and has found that they contain quite enough gold to warrant treatment in this way."

The owners of the Carlton gold mine, Yarmouth county, have decided to place a Wiswell Crusher to be run by water power, and have made a contract for the erection of steam hoisting and pumping machinery on their property. The lead has been opened in three places in a distance of 750 feet and the ore has been found equally rich in each shaft.

An exchange reports the sanitary condition of Springhill as deplorable, the water bad, and epidemic diseases very prevalent. A great many accidents, some of them fatal, have recently occurred at these coal mines.

The Clementsport *Courier* announces the discovery of gold by prospectors at a place about five miles from that town. Specimens shown to a *Courier* representative are said to indicate a rich find.

Mr. A. A. Hayward, has purchased the Cochrane Hill property, located about eleven miles from Sherbrooke, Enysboro' County. The property, which was sold by the Sheriff, contains a fifteen stamp mill, large boilers, and is also well equipped with hoisting and mining gear.

The same gentleman is also the proprietor of Empress Mine, where he is meeting with great success. The following particulars of the work being done there are gleaned from the *Critic*: "The main shaft is now down to a depth of 320 feet, and as soon as the large plunger pump, which is now being put up, is in working order, it (the main shaft) will be rapidly sunk upon. There is now over 76,000 feet of stoping ground open, and ore enough at hand to last a 15 stamp mill two years. All the latest labor-saving appliances have been introduced into the mine, and the mining is conducted on scientific principles, guided by great practical experience. No. 5 shaft to the north of the main shaft, has been sunk to a depth of 200 feet and connected with the main shaft and shaft No. 2 by two cross cuts, one at 100 and the other at 200 feet in depth. Good pay ore has been found in the cross cuts and shafts. The Harding mine averaging 71 $\frac{2}{3}$ cents a foot. Shaft No. 5 and drifts to the north, averaging \$1.50 per foot. Shaft No. 3, 52 $\frac{1}{4}$ cents, and No. 2 level west from shaft No. 3, 50 cents per foot. Overhead stoping is the rule, the detached ore dropping by its own gravity into receptacles, from which it is loaded on the ore cars and raised to the surface without handling. At the surface the ore is dumped automatically, and is soon being crushed under the ponderous stamps of the mill."

We learn that as a result of enquiries made at the Colonial Exhibition, regarding the exhibits of briquettes, a prominent English consulting engineer has been placed in communication with Cape Breton manufacturers, and if sufficient slack coal can be obtained at the different collieries of the province, there seems to be good prospects of extensive works for the manufacture of this fuel being erected there. These briquettes contain about nine per cent. of coal tar pitch, and are said to be admirably adapted for steam purposes, particularly for locomotives.

We learn from the *Engineering and Mining Journal*, that negotiations are in progress at Halifax between the representatives of a New York company and John Grenier for the purchase from the latter of two coal and copper mining properties in Cape Breton; \$200,000 is asked. The copper areas begin at George River Mountain, and extend westerly ten miles along the southern side of Little Bras d'Or, being divided into four blocks of five square miles. The coal areas cover fourteen square miles, and are situated between Lingan and Sydney, near the General Mining Association's property.

The *Critic* is our authority for the following item from the Oldham district: "Mr. E. C. McDonnell brought into town a brick of 140 ozs. of gold, the product of 65 tons of quartz, being the result of six weeks' work by 20 men. The ore was taken from the Dumbrack lead, which averages about six inches in thickness, and was mined from a tunnel at the depth of 250 feet. The main shaft has reached a depth of 315 feet,

the quality of the ore steadily improving as the lead is sunk upon. Mr. McDonnell has been mining for over 23 years, 14 of them on his own account, and has probably paid as much money in royalties as any mines in the Province. The mine is equipped with one of Mumford's patent boilers and a good hoisting engine, and has proved a most profitable investment for its owner."

Quebec.

The phosphate property at High Falls has been sold by its owner, Captain Bowie, for \$10,000.

Mica is reported to have been discovered on the property of Mr. Lemires at St. Ambroise de Kildares.

Dr. C. Le Neve Foster, H. M., Inspector of Mines for North Wales, who was appointed by the Royal Commission to report upon the minerals and rocks shown at the Colonial Exhibition, has expressed a most favourable opinion of the slate exhibited by the Rockland Slate Co. of Montreal. This gentleman has had under his supervision many of the celebrated Welsh slate quarries and he states that although the slate exhibited does not split as smoothly as the Welsh slates, and therefore does not look as well in a rough state, it is fully equal to the best Welsh slate when planed or otherwise worked. The slabs exhibited by the company are very large and the slate is free from iron pyrites, which are often present in the Welsh slates, and by its decomposition, stains them with spots of iron rust. Dr. Foster, like a number of other gentlemen interested in the slate business who have visited the Canadian section, spoke very highly of the manner in which the slate washtubs sent from Montreal were put together, and thinks that the slate workers of Wales might, in this manner, very profitably take a lesson from their Canadian brethren.

Ontario.

Specimens of copper from the deposits at Sudbury were forwarded to the Colonial and Indian Exhibition.

Copper from this mine is being shipped at the rate of ten cars per week to the smelting works in New Jersey.

The rush of miners and speculators into Sudbury has become so great that prices for food and lodging at that place are exorbitant.

The C.P.R. have constructed a side track from the Algoma branch into the portion of the newly discovered copper mines at Sudbury. They are also laying for the owners of the mines another branch to run to a point at the mines about four miles distant.

THUNDER BAY DISTRICT.

The Silver Mountain mine has been sold to an English company for \$175,000. Work will be commenced at once under the supervision of Mr J. Tretheway. The chairman of the new company is Mr. J. A. Tobin, a director of the Liverpool, London & Globe Insurance Co., and on the board of management is the name of Sir Alex. Galt. The capital is placed at \$500,000, all paid up, and it is stated that fully \$200,000 will be available at once for working expenses. The property was purchased from Messrs. Oliver Dounais, J. Tretheway, R. Tretheway and J. Gifford. The vein, which is located on locations R53, R54, was discovered by an Indian in September, 1884.

In addition to the east end of Silver Mountain the Port Arthur *Sentinel* advises that the company have purchased other mining locations as well as about one thousand acres of land from the Ontario government, so that they now control absolutely over fifteen hundred acres, all of which they expect to use in the development of their mine. Two of the locations purchased from private parties cost the original owners about \$100 each, and were purchased by the company for \$1,000 and \$2,000 cash respectively, after being held only about a year.

The Silver Islet mine is to be pumped out, with a view to again working it.

It is not improbable that work will be suspended for the winter at the Peerless mine.

Valuable silver veins are reported to have been discovered on Arrow Lake, a few miles from Whitefish.

Rice leaf silver is reported to have been struck at the Elgin mine. This property is located near the Beaver mine, and is on the same range.

A fourteen foot shaft has been sunk at the Elgin mine. Four men are working the claim and the indications are said to be good.

Mr. C. J. Johnson has taken patents for a large tract of land some 35 miles east of Port Arthur which is said to contain rich deposits of silver lead.

Operations are temporarily suspended on account of the water at the Silver Falls property. After the water has been pumped out work will be resumed.

Iron is said to have been discovered a short distance west of Lac des Mille Lacs. An exchange informs us that negotiations are now in progress with a Chicago company to operate this deposit.

Writing of these and other iron ore deposits in the Thunder Bay District the *Miner* says:

"We believe that we have some of the largest deposits of iron of any district in America; and if this is the case, we have no fear that we shall be able to find a market for it; for the vast consumption, and rapidly increasing demand for the products of iron ore in the United States, places us in such an advantageous position, that it will become almost imperative that the United States draw their principal supply from us. It is almost pretty generally known that unlimited quantities of iron ore exist on Lake Winnipeg, and in the district between this lake and Hudson Bay; and we have no doubt that in a short time, with proper railroad facilities, this vast district will become the great mineral reservoir, for the whole Dominion of Canada, and probably for the United States."

The Fort William *Echo* gives the following particulars concerning the iron deposit owned by the McKellar Bros. and Graham, Horne & Co., on the Atic Okan river (near the Seine):—

"The rich iron ore occurs in a great lode or belt with one and in places two partings of silicious, chloritic and dioritic schist, 10 to 50 feet in thickness of 100 to 150 feet. The iron lode conforms with the associated strata and dips north at an angle of about 80 degrees to the horizon, and shows the rich body of ore along the strike for a distance of nearly a mile and a

half, the ore holding its full size along the middle position for about half this distance. It forms a mountain range along the whole way, that rises to an elevation of about 100 feet above the level of the surrounding plain for a good portion of the distance; so that it presents excellent facilities for extensive and cheap mining."

The quality of the ore as shown by Professor Chapman, the great authority on iron ores in Canada, is second to none. He states, in the certificate of analysis, "so far as regards composition and physical characters, a better ore could not be obtained." He shows the ore to contain 70.06 per cent. metallic iron, no titanitic acid, and only a very small amount of sulphur, and phosphorus, practically none, the balance being alumina and silica.

LAKE OF THE WOODS DISTRICT.

A sixth interest in the Gold Hill location has been sold for \$500 to Mr. A. Gillis, of Belleville, Ont.

It is rumored that Mr. Dobie has refused \$15,000 for a one-sixth interest in the Pine Portage Mine.

The Gold Mining company have been compelled to stop work on their property near Rat Portage by a Mr. Mather, who claims the mineral under his timber lease.

The miners in the vicinity of Rat Portage have taken steps to petition both the Ontario and the Dominion Governments against the difficulty of securing valid titles to their properties, many of them have been waiting since 1879 for a title to their claims and their patience is becoming exhausted.

Manitoba and N.W.T.

Sir Alexander Galt reports that the coal taken from the mines at Lethbridge improves in quality the further in operations are carried. It is now selling at \$6.50 on the cars, and \$7.25 delivered. He expects that the output for the winter will increase to 400 tons per day.

The first meeting of the Canadian Anthracite Coal Mining Company held at Winnipeg on the 16th November elected the following as directors: McLeod Stewart, Ottawa, Ont., president; Senator Thorp, Eau Claire, Wis.; vice-president; H. Ingram, President of the National Bank, Eau Claire, Wis., treasurer; A. Puge, St. Paul, general-manager. Messrs. Dennis Ryan, John Stewart, W. B. Scarthe, E. A. Bronson and Archibald Stewart are also mentioned as directors of the company. The subscribed capital of the new company is \$500,000.

This company has been formed to develop the deposit of anthracite coal in the vicinity of the Cascade mountain, 75 miles west of Calgary. It owns 1,360 acres of land containing the whole of the available deposit. The seam or vein has been reported by Dr. Geo. M. Dawson, Assistant Director, Geological Survey, and others, as measuring at the further opening four feet and eight inches in thickness, having increased from its outcrop to this width from four feet. It is five feet and two inches in thickness at the Black Diamond or Hughes mine, nearly three miles distant. The stratum may, therefore, be regarded as having an average thickness of 5 feet with but little, if any variation. From a calculation made by Mr. C. D. Wilber, Inspector of mining properties. In Chicago, it is estimated that every three feet of stratum will give 7,392 tons; and 300 feet will give 100 times as much or 739,000 tons. Reasoning on this basis

the company calculate that at a trifle over 400 feet in depth that there are 1,000,000 tons of anthracite coal.

The Manitoba *Free Press* says that with careful management and having the co-operation of the Canadian Pacific Railway, whose desire it is to foster enterprise, which will build up and develop the mineral resources of the far west, the future of this company is of a promising character. The development has been going on for the past month under Pennsylvania management, the promoters being desirous that the best seams be tunnelled and developed, and the coal properly prepared before placing it on the market.

British Columbia.

A one-fourth interest in the old Channel Company in the Granite creek district was recently sold for \$750.

There is a vital necessity for a waggon road from Columbia River to McCulloch Creek in order that supplies and machinery may be brought in.

At the mouth of Cairn's Creek (30 miles from Revelstoke) J. H. Cameron has staked a large claim, and is now on the ground making preparations for work next season.

A prospecting party have discovered gold at a creek about eighty miles from Barkerville. The specimens shown are good and miners will go to the new gold field in spring.

A number of parties are prospecting in the vicinity of Slate creek. From latest reports some excitement exists over the reported find of a \$215 nugget in the neighborhood.

A fine seam of coal $5\frac{1}{2}$ feet thick has been struck by the East Wellington Colliery. It is also reported that the level running down the valley from No. 3 shaft of the Wellington Collieries has also opened up a splendid seam of superior coal.

A large number of quartz claims have been taken up and prospected in the Big Bend district, 70 miles from Revelstoke, on the Columbia River. Sufficient work has not been done on any of them yet to test their richness, but old miners pronounce the indications as very favorable.

In the same district a short distance from the claim of Messrs. George Platt & Co., a farmer from Manitoba is industriously at work fluming a canyon, an undertaking which is pronounced by those who have seen it, to be one of the greatest exhibitions of pluck and perseverance in the history of mining.

At a meeting of the B. C. Mining Company, held at Victoria on Thursday 21st ult., arrangements were made to extensively prospect their property known as the Cariboo location. The present shaft will be straightened and sunk lower, cross-cutting and drifting in the descent. The estimated cost of the work is placed between five and six thousand dollars.

Rumours of a rich find on Vancouver Island are prevalent in Victoria. A *Colonist* representative states that he has been shown a specimen seamed with gold, which contains as much of the precious metal as quartz. It is he says larger

than a man's fist, weighs three pounds four ounces, and is estimated worth over \$80 in gold. Some suspicion exists as to the truth of the story.

Specimens of quartz taken from the ledges known as "Senator Jones" and "Governor Perkins," near Lowhee creek, were recently forwarded to the Government Assay office and have netted from \$55 to \$150 to the ton. The vein is thought to be a continuation of the "Bonanza" ledge owned by the B. C. Mining Company.

As an instance of the recent revival in quartz rock in the vicinity of Richfield, it should be stated that no fewer than 39 registrations of quartz were made during September at the Government office of that place, while applications for mining ground, water privileges, free miner's certificates, new, and renewals, are of daily occurrence.

Recent tests made of the quartz ledge, commonly known as "Perseverance Claim," near Coldstream are thought to be sufficiently good to induce the locators to proceed with the work of prospecting the property. The ledge is one foot thick on the surface, and widens to two feet at a depth of six feet. The locators entertain the belief that it will improve as it is further developed.

Mr. McCullum who has been for the past sixteen months in the mines at the Big Bend district has arrived in Victoria. He reports very favorably of that district. Mr. S. Adler who has arrived in Victoria, Granite Creek, describes it as the worst mining camp he has known since 1850. Those who are remaining are only holding on in the hope of an improvement. If gold is secured in paying quantities it will be found in the hill claims. Some of these latter have paid wages. A house that cost \$600 in labor alone was sold for two glasses of whiskey. Another that cost \$1,500 was sold for \$15 and cut into firewood. Goods are being sacrificed. About forty white men still remain.—*B. C. Colonist*.

A correspondent writing to the *Colonist* regarding the mines at Misquito Creek says that: "The Discovery," last year took out \$10,000; but this year they had just struck good pay when the water gave out. They are now bringing in a ditch five miles, and when this is ready it is expected that a continual head of 200 inches will be had. Above this claim is that worked by Plyn Bros., which also suffers from a lack of water, though last year it paid well. They were engaged in cleaning up at the time of our visit and we saw a couple of pans of dirt worked. A couple of shovels of a mixture of mud and gravel were placed in the pan and then worked with water until nothing was left but the gold. It had almost all been washed away and we thought there was not a color, but a minute more disclosed several nuggets which weighed \$6 in all. The second pan furnished \$3. No wonder there is a resistless charm about the rough labor when from the earth a miner can wash the glittering yellow gold. The gold of Mosquito creek is of the finest character found in Cariboo, weighing \$19 to the ounce.

Recent events, writes an English financial paper, have made it so thoroughly manifest that the British investor has a liking for gold mines that it is much to be regretted that energy is lacking in the development of the gold-bearing districts of British Columbia. Here is a vast

and sparsely populated region, rich in mineral resources: who will take it in hand? Mr. Koch, from whose report to the gold commissioner of the Cariboo district we recently quoted, points out that as yet there has been nothing like an adequate examination of the gold quartz deposits in that part of Her Majesty's dominions. He makes special reference to Hixon creek, where he superintended operations in the hope of finding a paychute of quartz. "A shaft was sunk, and at a depth of 60 feet a drift was started, and the vein was found at the exact point where it was estimated to be, and no vein in California has truer or better defined walls." Mr. Koch proceeds to admit that it is quite possible a greater depth must be reached before paying quartz in large quantities will be obtained, but he expresses himself satisfied with the results of recent prospecting, and declares his opinion that the gold quartz deposits of the district are not merely local, but that a regular and unbroken formation exists; that this continues for many miles, and that true fissure, and even contact, veins of gold and silver can be found by intelligent prospectors. If this belief be well founded most people will be of opinion that intelligent prospectors had better set to work at once—unless, indeed, they are afraid that the authorities of British Columbia, following the example of the Dogberries of Queensland, are only waiting until English capital has been invested in their mines to give the whole business a gratuitous but official black eye.

Mr. Ames Bowman, M.E., of the Provincial Government geological staff, has expressed a most favorable opinion of the mineral resources of the Cariboo district. He has just returned from the work of occupying a large number of additional triangulation stations for geography, and has been following the formations, and placer mines, and quartz ledges in detail. The principal quartz ledges in the old placer district were visited, to trace, as far as possible, the connection between the ledges and the placers, and particular attention was given to the strike of the rocks containing the auriferous deposits. In this way the gold belt has been traced and segregated from one end of the country to the other. Mr. Bowman states that to the north-eastward there is a newer formation, differing entirely from the slate country of Cariboo, in which mining has been profitably carried on. In this fossils have been found, showing it to be newer than Cariboo, but older than any of the gold-bearing country in California. In the southeastern corner of the field work is a formation newer than the gold-bearing country of California. He advocates the adoption of central chlorination works or leading establishment which would form a market for the products of the mills and to show the necessity for this describes the process as follows: "There are three different kinds of roasting furnaces in general use; first, the reverberatory in which the ore is shovelled from one end to the other as in a bake oven; the cylinder, where the same thing is done mechanically; the Stetefeldt furnace in which it is dropped down a shaft, falling from one shelf to another until the sulphur is burned out. The roasted ore, which is now a fine dust, is placed in a tank or tub, saturated with chlorine gas and leached out with water; it now being in the form of a red mud is placed in crucibles and converted into bullion. Thus, if the roasting is not done just right, much gold is lost. It is evident these are all expensive appliances and require skill. An immense quantity of ores requiring that treatment are in the Cariboo district and properly managed chlorination works would prove a profitable in-

vestment to all concerned. In case silver occurs with gold a different process of leaching is required, but the method does not vary materially. In the event of chlorination or leaching works being available, people having ledges would merely dress their ores in a form which would bear transportation to a considerable distance, occasionally on horseback with profitable return. Such a custom works would thus allow men of small capital to successfully work ledges, as they would be in a similar position to the farmer who brought his wheat to a grist mill to be ground into flour.

Vertical shafts are preferable to inclined shafts when heavy pumping machinery has to be put up, for pumps and rods are more easily fixed and require fewer repairs when they are arranged vertically. However, many metallic mines may be quoted, especially in England, where large engines, work pumps in inclined shafts or in shafts which have been sunk vertically, when they intersected the deposit and have then been carried on along its dip. This arrangement of inclined shafts is justifiable in working alone when the enclosing rocks are very hard. In this case in fact, an inclined shaft allows the lode to be studied in detail during the sinking itself. If, however, a large output is required the preference should certainly be given to vertical shafts, for, in order to obtain such a result, great loads must be raised, at velocities which are only admissible in vertical shafts, furnished with the best system of quives.

MINING REGULATIONS

To Govern the Disposal of Mineral Lands other than Coal Lands, 1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

RED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

A. M. BURGESS,

Deputy Minister of the Interior.

The Intercolonial Railway of Canada, AND FREIGHT ROUTE BETWEEN Canada and Great Britain

—AND—

Direct Route between the West and all points on the Lower St. Lawrence and Baie des Charleux, also New Brunswick, Nova Scotia, Prince Edward Island, Cape Breton, Newfoundland, Bermuda and Jamaica.

New and Elegant Pullman Buffett Sleeping and day cars run on through Express trains.

Passengers for Great Britain or the Continent, by leaving Toronto at 8.30 a.m. Thursday, will join Mail Steamer at Halifax a.m. Saturday.

Superior Elevator, Warehouse and Dock accommodation at Halifax for shipment of grain and general merchandise.

Years of experience have proved the Intercolonial in connection with Steamship lines to and from London, Liverpool and Glasgow to Halifax, to be the quickest freight route between Canada and Great Britain.

DEPARTMENT OF INLAND REVENUE.

An Act respecting Agricultural Fertilizers.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, or offers or exposes for sale, any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells, or offers or exposes for sale, any fertilizer which does not contain the percentage of constituents mentioned in the manufacturers' certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars; Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALI,

Commissioner.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office until noon on Monday, the 1st day of November next, for four timber berths of ten square miles each, more or less, numbered respectively 4, 5, 8 and 9, situated on Kicking Horse River and Ottentail Creek, a tributary of the Kicking Horse River, near Field and Ottentail Stations, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately of these berths, together with the conditions on which they will be licensed, may be obtained at this Department or at the Crown Timber Offices, Winnipeg, Calgary, N. W. T., and New Westminster, British Columbia.

A. M. BURGESS,

Deputy of the
Minister of the Interior.

Department of the Interior,
Ottawa, 14th August, 1886.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office up to noon on Wednesday, the 1st day of December next for three timber berths of fifty square miles each, more or less, numbered respectively 16, 17 and 18, situate on the west side of the Columbia River, near Golden City Station, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately, of these berths, together with the conditions upon which they will be licensed, and the forms of tender therefor, may be obtained at this Department or at the Crown Timber Offices at Winnipeg, Calgary, N. W. T., and New Westminster, British Columbia.

A. M. BURGESS,

Deputy of the
Minister of the Interior.

SEALED TENDERS, addressed to the Post-
master General will be received at Ottawa until
noon on FRIDAY, 17th December, 1886, for the
conveyance of Her Majesty's Mails, on a proposed
Contract for four years, three times per week, en-
route, between ASHTON and PROSPECT, from
the 1st January next.

Printed notices containing further information
to conditions of proposed Contract may be seen at
blank forms of Tender may be obtained at the Post-
Office of Ashton, Munster, Dwyer Hill and Pros-
pect, and at this office.

T. P. FRENCH,

Post Office Inspector.

Post Office Inspector's Office,
Ottawa, 23rd Oct., 1886.

Notice to Contractors.

SEALED TENDERS addressed to the under-
signed will be received at this Office on
FRIDAY, the 19th instant, for the Clearing and
Removal of Snow, etc., from the Public building
Ottawa; and also for the Removal of Snow, etc.,
from the roofs of buildings, out-buildings, walk-
ways or roads, etc., at Rideau Hall.

Forms of Tender and Specifications can be had
at this office, where all necessary information can
be obtained.

Separate Tenders will be required for each work
and must be endorsed "Tender for Removal of
Snow, Public Buildings," and "Removal of Snow
Rideau Hall," etc.

Each tender must be accompanied by an accepted
bank cheque made payable to the order of the
Honorable the Minister of Public Works, for the
sum of five per cent. of the amount of the tender, which
will be forfeited if the party decline to enter into
contract when called upon to do so, or if he fail to
complete the work contracted for. If the tender
not accepted the cheque will be returned.

The Department will not be bound to accept
the lowest or any tender.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 10th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Mr. W. A. Allan, of this city, has shown us some very fine blocks of white marble which he has just received from his property in the Upper Ottawa district. The specimens are of a very superior quality, fully equal to the best Italian grey marble. The blocks are to be sawn and placed on exhibition at an early date.

In our last issue attention was drawn to the specimens of chromic iron recently exhibited at the Colonial and Indian Exhibition and to the deposits of this ore to be found within the Province of Quebec. We have since received a communication from an authority in that province who states that last winter the Hon. L. G. Ross and Dr. James Reed, Reedsdale, shipped several tons of the ore, averaging 50 per cent. of chromic oxide, to Philadelphia, at \$18 per ton of 1240 lbs. The ore was placed on the cars at this price at Robertson station, Quebec Central Railway (near the Thitford Asbestos Mines). Samples from the deposit assayed by Professor Ditmar, Anderson's College, Glasgow, average 52.48 chromic oxide. The ore is found in large quantities in lot 7, range 10, at Leeds, Megantic county, while another deposit exists on lot 5, in the 4th range, Thitford. The writer adds "that among other purposes it is used for rapid tannery, and that there is no difficulty in getting large quantities of the ore, provided remunerative prices could be obtained for it."

If testimony was required to demonstrate the great and valuable work that is being accomplished from year to year by our Geological Survey it is undoubtedly evi-

denced in the voluminous reports of its doings periodically issued by its eminent director, Dr. Selwyn. That for 1885 is before us, and like its predecessors it is, from beginning to end, replete with much valuable information regarding the topography, the geological structure, and the mineral wealth of our Dominion. As in former years the work of exploration and survey has been vigorously pursued over a vast area, portions of every province and territory from Nova Scotia to the Pacific coast, have been visited and investigated and a flood of new light has been thrown upon districts hitherto unknown or but imperfectly understood. To the public at large the report will prove of inestimable value while the student of our geology and particularly of our mineralogy will find within its necessarily condensed but very able summary, much useful matter of great variety and varied interest. The notes and statistics bearing upon our mineral resources are particularly worthy of attention.

Referring to the establishment of a mining and mineralogical department and the collection and publication by the Survey of statistics of mines and mineral product, a question which of late has been the subject of much wholesome discussion. Dr. Selwyn writes:—"I may say that after carefully considering the matter in all its aspects, I am led to the belief that the system I originally adopted, namely, that of issuing a circular with questions to be answered on a form printed for this purpose, and when convenient or considered necessary, to be accompanied by personal application on the ground, is that which is most likely to afford the desired result. There are two gentlemen, trained mining engineers, now employed on the survey, to whom the work of issuing, collecting and compiling the returns might be entrusted, and, and who might also each year visit and critically examine and report on one or two mining districts. In this way, every mining district in the country would be visited at intervals of one or two years, unless some special development called for more frequent examination. At present the chief mining developments are in the provinces of Nova Scotia, Quebec and British Columbia, and in each of these provinces the local government employs a mining inspector or engineer, who collects statistics and reports on the mines of the province.

"It would not, therefore, seem desirable or necessary that the work should also be done in these provinces by the Geological Survey, but with the co-operation and consent of the provincial authorities, the results obtained by their officers might be incorporated in the general statement issued annually by the Geological Survey, and thus gain wider publicity.

"So far as the special examination of mining districts is concerned, a commencement was already made in 1883 and continued in 1884, the districts examined being: In 1883, the Lake of the Woods gold region, and the phosphate region in the townships of Wakefield and Templeton; and in 1884 the Marmora gold and iron bearing region

around the north shore of Lake Superior; also some of the mines in the province of Quebec. If the scheme now proposed is carried out, no further assistance would be required, but the two gentlemen named, Messrs. E. Coste and E. D. Ingall, should be appointed on the permanent staff with the title of 'Mining Geologists.'"

Again we have to add that the establishment of a thoroughly organized and equipped Bureau of Mines and Statistics is of vital importance to the country at large, and that if there is to be such an establishment it must be founded on a permanent basis with an adequate and efficient staff. The work of collecting and compiling information and statistics in connection with Canadian mines and minerals is too important to be left to the tender mercy of any half-hearted organization, and it can never be done in a manner that will be acceptable to the mining public until such time as a distinct and separate department, thoroughly and efficiently equipped has been added to the Survey.

In another column our readers will find a reprint of Mr. Eugène Coste's valuable pamphlet, "Observations on Mining Laws and Mining in Canada," which is presented as Part K of the Annual Report, 1885, just published by the Geological and Natural History Survey of Canada. Mr. Coste, who, by-the-way, is a graduate of the School of Mines, Paris, and a mining engineer of marked ability, has had an extensive and varied experience of the mining districts of England and Europe, and his remarks on the state of the mining industry of our Dominion, and particularly to those districts lying within the Provinces of Ontario and Quebec, will be read with much interest. His suggestions for the better development of the mineral resources of the country are particularly well timed and worthy of the best attention.

Among other papers read before a recent meeting of the Mining Institute of Scotland, was one by Mr. David Reid, Glasgow, on "Pitkins Electric Safety Lamp." Examples of the lamp were exhibited and explained from which it was shown that it consists of a small storage battery encased in a light box with lamp attached capable of being carried by the miner into his working place. The lecturer stated that it gave a splendid light underground and that when perfected it would become the lamp of the future.

An effort is being made by several leading newspapers to impress upon the Dominion Government the necessity of giving adequate protection to our iron industry. The Montreal Star, handling the question editorially, says: "If it is not considered advisable at present to increase the custom duties on iron and steel there can be no general objection to the passage of an act obliging all railways receiving public assistance to use rails and rolling stock of Canadian manufacture. If such a law was passed and pamphlets descriptive of the

iron and coal deposits of the Dominion sent to the leading iron men of Great Britain and the United States there can be no doubt that capital would be brought into the country to develop our iron resources, and a great industry would be established on a paying basis. The first step should be to advertise for tenders for Canadian made rails for the extension of the Intercolonial railway through Cape Breton. If it were understood that, in future, not only Government railways, but all railways receiving public aid, would be obliged to secure their construction materials in Canada, there would be no difficulty in securing tenders. The construction of the railway through Cape Breton would perhaps be delayed for a short time by such an arrangement, but no part of the Dominion has more to gain from the adoption of such a policy than the island of Cape Breton. The *Island Reporter* recently claimed that the minerals of Cape Breton Island were worth more to the Dominion than all the farming lands of the great North-West, and certain it is that noted geologists have said that there is more coal and iron to the square inch in that end of Nova Scotia than in any other known quarter of the world. The island would certainly be benefited by the encouragement of the iron industry. By the immediate adoption of such a policy, the Government could prepare the way for a revision of the tariff, giving adequate protection to every branch of the iron and steel industry."

A statement which evidently emanated from the associated press agent at New Glasgow, Nova Scotia, recently gained currency to the effect that a very bitter feeling had been created by the action of the Manager of the Dominion Coal Mines at Westville in refusing to permit the men presently working on full time there to share their work with those of their fellows who had been thrown out of employment at the close of the shipping season. On enquiry it appears that the company made every effort to retain as many of their hands as possible and that at present there are more employees than their limited winter operations demand. This will be the better understood when it is learnt that the decrease of men is only 35 per cent., while the actual work done shows a falling off of 60 per cent. The criticisms which the action of the manager has involved seem to be uncalled for.

Mineral Deposits.

BETWEEN THE GREAT LAKES AND THE HUDSON BAY.

In an article to an esteemed contemporary on the metallic ores to be found between the great lakes and the Hudson Bay, Dr. Robert Bell of our Geological Survey writes: "Iron has been found in several places not far from Algoma Mills, and again at Desert Lake, north of the Bruce mines. A deposit of iron was reported on an island in Lake Nipissing by Mr. Murray, of the Geological Survey, nearly thirty years ago. Still farther north, toward James's Bay, is the largest iron deposit yet known in that whole country, and situated at the foot of the Grand

Rapid of the Mattagami River. It was first pointed out by me in 1875. Proceeding toward Lake Superior, very large quantities of iron ore are found, not far north of Batchawana Bay. I also found indications of large deposits of iron near the Montreal and Perch rivers. A deposit of hematite was discovered by one of my assistants on the Slate islands, in 1870, and some low-grade magnetite has long been known to occur at the mouth of the Little Pic River. To the north of this region, a perfect mountain of iron has been discovered by that fortunate prospector, Mr. Peter McKeller, of Fort William. It is back in the woods, in the unsurveyed region, about 200 miles northeast of Port Arthur. In my reports of 1869 and 1870, I mentioned certain discoveries of iron near Long Lake, on the south side of Lake Nipigon, on the Sturgeon River, some of which have since been found to be important. A comparatively valuable deposit of magnetite, in workable quantities, occurs near Silver Lake, not far from the head of Thunder Bay. Quite lately, a rich deposit of magnetite has been found on the celebrated 3 A silver location, Thunder Bay. Still farther west, during the past summer, two important discoveries have been made, one of them on the Atik-Okan (Reindeer Antler), just north of the south bend of the Seine River, about 100 miles northwest of Thunder Bay, and thirty miles south of the Canadian Pacific Railroad track. The ore is of first-rate quality, and described as occurring in immense quantities, and it is probable that it will be extensively worked before long.

The other large deposit occurs about 100 miles farther west, and is also south of the Canadian Pacific Railroad, at a considerable distance to the eastward of the Lake of the Woods. There is a rich deposit of hematite on Big Island in Lake Winnipeg. Between Lake Winnipeg and York Factory, on Hudson's Bay, at the narrows of Knee Lake, there is a large quantity of magnetite. I discovered one deposit of rich magnetite, in the region I was exploring this summer, but am unable to give particulars until I have made my official report.

Copper is known to exist in more or less promising quantities at numerous places on the north shore of Lake Huron. One of these is the Wallace mine, near Killarney, which was worked at one time for both copper and nickel. Then passing westward, the celebrated Bruce mines are situated about 40 miles east Sault Ste. Marie. Work was begun here in 1846 and continued until 1876. In the palmiest days of its enterprise, large numbers of Cornish miners were employed, and quite a town was built. In 1876, the mines closed, and it being the year of the Philadelphia exhibition, I collected statistics that showed the output during the thirty years to have amounted to \$3,300,000. Copper ore has been found in notable quantities at several points inland from the Bruce mines and around Echo Lake.

I have not yet examined the Sudbury mines personally, but at the time ore was discovered there, some three or four years ago, I had samples of all the different kinds sent to me. The first ore prepared for market amounted to about 3,000 tons, which, however, was of a lower grade than the producers supposed, and I was informed that, on the advice of one of their New York correspondents, they cobbled it over and reduced the 3,000 tons to 1,000, which was found to contain about 7 per cent. of metal. In my explorations in the extensive region between Lake Huron and Hudson's Bay, I have found many indications of copper, which have been reported from time to time. Among the earliest copper mining enterprises in Canada, were those of the

Quebec and British American mining companies. The works of the former were carried on at Namanise (Little Sturgeon), in the Lake Superior region. In later years the Lake Superior Native Copper Company carried on operations in the same neighborhood. Recently, this company has been reorganized as the Lake Superior Copper Company, but little is done at present. On Michipicoten Island, in the northeast angle of Lake Superior, a company, called the Michipicoten Native Copper Company, was organized a few years ago. After working a short time, this company was also reorganized, and last winter had a small force of men at work. At both the above localities, copper occurs in the native state. About forty years ago, numerous locations were taken up, principally in the names of gentlemen residing in Montreal, but which were held by the Montreal Mining Company. These were afterward sold to what was called the Silver Islet Mining Company, but more correctly the Ontario Mineral Lands Company. One of the locations thus taken up was the celebrated Wood's location, in which Silver Islet is situated. Some locations were worked near Nipigon Bay and southwest of Thunder Bay. I have found indications of copper in many places northwest of Lake Superior.

The principal deposits of lead in the district under consideration are at the Victoria mine, near Garden River, a short distance east of Sault Ste. Marie. This mine was principally owned in Quebec City. A short distance to the north of that, another lead mine, the Cascade, has also been worked to some extent. On the northwest side of Black Bay, Lake Superior, a rich vein of lead was worked by the Enterprise Mining Company. Other large deposits of this ore are known to exist in the same neighborhood, but, owing to the very low price of lead at the present time, there is not much inducement to open them. Around Thunder Bay also, a number of lead-bearing veins have been discovered. Lead occurs in several localities on the Lake of the Woods.

Silver is also well represented. It was first found many years ago on Lake Superior, notably on Michipicoten Island, and Prince's Location, not far from Port Arthur. But the first discovery of silver to attract public attention in late years was that afterwards known as the Thunder Bay mine, situated about three miles northeast of Port Arthur. Here, native silver was found in large quantities, in quartz at the outcrop of the vein. The mine promised to be so rich that immediate steps were taken to prevent its being plundered, owing to the silver being so easily obtainable on the surface. Attempts were made to open the mine, but from various causes, prominent among which was bad management, it never made a success, and has been closed for some years. A short distance southwest of Thunder Bay, another mine was discovered and worked under the name of the Shuniah mine, afterward changed to the Duncan mine. The celebrated Silver Islet mine was discovered in 1868, while Wood's Location was being surveyed by Mr. Thomas Macfarlane, now chief analyst in the Inland Revenue Department here. One of the first blasts at the surface of the vein threw out silver ore to the amount of \$1,500. The mine was worked to the depth of 1,200 feet, and \$2,500,000 worth of silver is said to have been produced. The silver mines at present attracting attention are situated inland or in two groups at twenty-five and thirty-five miles southwest of Port Arthur, in the White Fish River region. The mines in which most work has been done are the Rabbit Mountain, Beaver, Porcupine, and East and West End Silver

Mountain. The three first mentioned are actively worked, and quite lately, the East End Silver Mountain was sold to a joint-stock company in Liverpool for \$150,000 cash, and the company has undertaken to spend a still larger sum on the property.

Traces of gold have been found in various places north of Lake Huron. On Lake Superior a vein containing visible nuggets occurs in Jackfish Bay. On Partridge Lake, nearly one hundred miles to the northwest of Port Arthur, small nuggets are disseminated through a large mass of quartz, and some distance west of this locality another rich gold-bearing vein has been discovered. The Huronian mine, owned by an Ottawa company, is situated near the height of land about one hundred miles west of Port Arthur. Here, a well-marked vein has been worked to some extent. A crushing-mill has been erected, but the principal impediment in the way of the working of this mine is the want of transportation facilities. A good road to the mine has become absolutely necessary. Coal has also been discovered in numerous localities on the Lake of the Woods, but at present little or nothing is done.

Personal.

Our readers will be glad to learn of the return from Britain of Dr. A. R. Selwyn, director of our Geological Survey. Dr. Selwyn held the position of Canadian Commissioner to the late Colonial and Indian Exhibition, and was created a C. M. G. by Her Majesty the Queen.

Phosphate Mining.

THE HIGH ROCK MINE, BUCKINGHAM.

The reports received from this mine are very satisfactory, and indicate that during the past year, operations have been actively pursued and that many important improvements have been made.

Five pits are now working, and at the deepest of these, that known as No. 8, where some 180 feet has been sunk, the miners are at present drifting in the bottom on a paying vein of phosphate about three feet wide. At No. 5 pit, the well-known "Bonanza," they are also drifting at a depth of 160 feet on a vein ranging from 1 to 4 feet in width, which is also paying well. No. 11 pit, 75 feet deep, is reported to be the best, and there, running under the hill on a 500 feet level, the management have discovered a vein of the purest ore 30 feet wide by 15 feet high. Mr. Pickford, the manager, says that "it is the finest show which has ever been seen on the hill, it having yielded last month 296 tons with an average of ten men."

The output for November, 704 tons, is the best on record at the mine, while that for December would probably have exceeded this but for the holidays. As it is, the output will be considerably over 600 tons. So satisfactory are the present state of affairs that the company contemplate increasing the staff to 250 men next summer, and working them in night and day shifts. At present about 120 men are employed.

During the past summer a tramroad extending from the mines to the river landing, two miles in length, has been constructed and some 6,000 tons of ore have been transported over this. It should be mentioned that the total shipment for this season was 6,349 tons, and that this is the largest quantity ever shipped from this property in any one year.

Under the management of Mr. W. W. Pickford, who has so ably conducted the mine since 1884, tramroads have been constructed, new machinery erected, and many other valuable improvements made. Not a little credit is due to this gentleman for the very satisfactory condition of things at this property.

Graphite.

Although Graphite has been known from time immemorial, and its name at once indicates the antiquity of its principal use, its geological origin is still a matter of doubt, and its properties not yet half understood. It belongs to no particular geological horizon, but occurs in rocks of all ages, in beds; imbedded masses, laminae, or scales, more commonly in granite, gneiss, mica, slate, crystalline limestone, and occasionally with deposits of coal. The famous Borrowdale variety is found in nests, in trap, in clay slate. Nearly every locality presents it in some new association, so that it is scarcely to be wondered at that geologists have been puzzled to account for the origin of a mineral that makes its appearance in utter disregard of the laws of deposition, stratification, injection or age. The recent progress of chemistry has thrown some light on this subject, and new theories have been advanced, tending to dispute the vegetable origin of graphite, and to explain its presence on the principle of the decomposition of cyanogen or of other intro-carbon compounds. In the preparation of caustic soda, cyanide of sodium is produced, and when, in the course of the operation, Chili saltpetre is added, to oxidise the sulphides of iron and sodium, and the mass is in a state of fusion, graphite arising from the decomposition of the cyanide rises to the top, where it swims and can be skimmed off, washed and dried, when it presents the appearance of brilliant, light power, perfectly pure and admirably adapted to the manufacture of pencils, and many other purposes. The brilliant, red crystals which form in blast furnaces and now and then give rise to what is called "salamander," were formerly supposed to be pure titanium. Wohler afterwards shewed that they contained cyanogen, and this discovery, together with the appearance of cyanogen in the soda ash manufacture, has led chemists to suspect that the formation of artificial graphite in iron furnaces is not always one to the solution of an excess of carbon in the molten iron, but may be referred back to a compound of nitrogen with carbon, in other words, to the decomposition of cyanogen. Applying these observations to geological phenomena, some authors seek to account for the formation of graphite in nature, on the principle of the chemical decomposition of the cyanides. It is certainly a very ingenuous theory, and has many strong points to sustain it, and as it may finally conduct us to an artificial method for the production of graphite, in any quantity and at reasonable rates run it deserves the careful study and experimental research of all parties interested in the development of this branch of industry.

The *Times* announces that a second assay of rock from the Cowichan ledge, B.C. discovered and located by Mr. Hugh Bell, of Somenos, went \$18 of gold to the ton, and a little silver. Both of the samples referred to and a former sample assayed a week previous, went \$20 in gold, and were from surface rock. It is thought likely that when the lode, which is an extensive one, shall have been sunk upon still better results will be developed.

British Columbia Milling and Mining Company.

Report of Mr. E. A. Koch to Joseph Heywood President of the Company:—

SIR.—At the request of Mr. Joseph Mason by telegraph, dated the 4th inst., I have carefully examined your property, consisting of the American, Cariboo, St. Laurent, and Wilkinson claims, together with the machinery stored in the two buildings. The most prominent surface indications of the existence of mineral-bearing veins I find in this district is the extremely large chimney or blow-out, of quartz, which comes to the surface near the line dividing the St. Laurent, and Cariboo claims. It is a very prominent feature and of itself speaks well for the vein, as samples taken from it for a distance of 750 feet, or up to the centre of the Cariboo claim, immediately over the deep shaft, showed gold in four separate assays ranging from traces of gold up to \$7.30 per ton of 2000 pounds: While its prominence and showing of gold would have been encouraging, that of itself would not by any means have been sufficient to justify any extraordinary expense except by way of prospecting in sinking, say one hundred feet on or near it, and then cross-cutting the vein and drifting some distance on it.

But the 50-foot shaft, sunk some 700 feet from the great blow-out or chimney, has to a great extent done the developing mentioned above.

The tunnel which taps the vein is driven in the hill about the centre of the three first mentioned claims and taps and cross-cuts the vein fifty feet from the surface, where the vein continues its course as on the surface, a little west of northwest, and at that point I find the vein between walls to be 17 feet. It is true, a large amount of slate (all of which is highly metaline) is more or less intermixed with the quartz in the vein.

The greater portion of the ore at that point is white quartz, which carries about \$3 per ton of gold; yet in many places the ore is heavily charged with sulphurets which assay from \$3 to so high as \$120.70 per ton; while the entire mass of the vein is highly colored with copper stains, which is indicative of a strong and living vein. You could not have done otherwise than continue your shaft below the level of the adit, with such encouraging prospects and assurance of developing a good mine.

I carefully examined your waste dump that came out of the shaft, as well as the ore now in the ore-house, and the discarded ore, which had been thrown out as refuse. I made one assay of the waste dump, and two from the refuse ore, while I carefully sampled the ore in the ore-house, from which I made three assays.

My assay from the waste dump showed \$6.20 per ton, while it is quite possible that some will assay much higher, while other samples will only show traces of gold; yet I think eventually it will all be milled.

The two assays from the discarded ore went \$4.30 and \$47.03 respectively, while the samples from the ore-house assayed \$14.20, \$86.03 and one traces of gold only. I made several other assays, which I kept no note of. I made them in order, if possible, to ascertain which particular class of sulphurets carries the gold, as in some of my assays of ore from different mines, the show is very encouraging, while in others the showing of gold is small while the ore looks equally good.

You are no doubt aware that the vein is not exposed by any work done on the St. Laurent or American claims, yet beyond a doubt the vein is continuous, and not only passes through the

claims but also far beyond, as is evidenced by the work done in the Pinkerton shaft, some 3,000 feet northwest from your shaft.

True, the work in that shaft only exposed a small, *or supposed small*, vein, the ore from which shows about the average amount of gold shown in the ore taken from the Cariboo shaft. As regards the narrowness of the vein at that point, it can be accounted for, in two ways; first, it is true the ownies cut through the ore, coming to a *supposed* slate wall, but it is quite possible, had they cut through the slate more ore would have been found. (See report to government.)

Yet, I will admit, it is possible that they did cut through all the ore that existed at that point; but it must be remembered that veins do not continue the same width to great distances, and even where they do continue the same width between walls, they do not always carry the same width of ore; nor must you be surprised in working your mine, to sometimes come upon places in your vein which do not carry any ore at all; but your mine is, however, safe if you continue to have good walls.

Thus the necessity of keeping a mine well prospected and open, in advance of the capacity of the reduction works, not only to insure a steady supply of ore but to guard against delay in case of an accident in any part of the mine. Returning to the southeast end of the St. Laurent claim, no work has been done to expose the vein; yet it can be traced where it crosses Stout's gulch, and again at the canon, as it passes up through the "Black Jack" hydraulic claim towards the Wilkinson, and old Prosperine claims and *not* making an angle and passing below the old Cooper shaft and to the Vivian claim as formerly supposed.

In fact, so far as developments have been made on the mines of this district, your vein *surely deserves* the name *it is known by*, viz., "Bonanza." Some would go so far as to assert that you have a great mine; I cannot do so. I will, however, go so far as to say that your showing is exceptionally good. Few mining men in any country have such encouraging prospects upon which to commence operations. The increase in the percentage of the sulphurets denotes a continuance or permanency of the vein. You will not be likely to find such a high percentage of sulphurets in all the workings of the mine, any more than you will always be likely to have a 22 foot vein, yet sufficient can be seen to justify the erection of permanent hoisting and pumping machinery.

I find amongst your machinery, power sufficient for a 40-stamp mill, with sufficient power to spare to drive the necessary concentrators.

The pans, and immense amount of accompanying machinery, are useless in this district. A very small percentage of the gold will be saved in the batteries and outside plates. The pulp must then pass over concentrators, where from 70 to 80 per cent of the sulphurets are gathered; they must then be roasted in order to de-sulphurize them, when they are then chloridized. The process is not so expensive as continuous amalgamation (pan process), as the original cost, including freight, engine power, steam to drive them, wear of pans, shoes, etc., makes continuous amalgamation in a district like this extremely expensive. True, you lose the use of your pans but you gain power for 20 more stamps, which, with your mine, I think a great item, as I deem it advisable to *crush* all the ore as it comes from the mine, as it is a very difficult matter to select gold quartz unless you know that you are passing through a barren place in the vein. There are three kinds of concentrators now in use in California, the True, Challenge, and

Golden Gate, all good. I, as others, have a choice. I must not neglect calling your attention to the fact that the greatest care should be taken of boilers in so remote a district as this; not alone in order to save the cost of buying and shipping, or repairing, but because when a boiler has to be repaired or replaced, either the mine must close down and fill up with water, or the mill hang idle, which always means a stoppage of income while expenses go on. I recommend that all boilers in this district have attached to them a Llewellyn filter and heater (Address J. M. Streeten, rooms 7 & 8; 330 Pine street, for circular), universally used in San Francisco and the largest mills in the country. There may be others equally good, but they are not in use in California.

I can say but little in reference to the Wilkinson claim. I have been to the mine four times and fail to find any cause to change my original opinion of the ground: I can say nothing to justify but one opinion, and that is, that it is a continuation of the Bonanza vein, and while nothing positive can be said as to the width of the vein at that point, sufficient has been shown, by work done on that claim, as well as on the Prosperine (some 400 feet to the south-east), to justify me in thinking the vein is large and strong at that point.

The Wilkinson shaft has caved so badly that it would be folly to re-open it. I find many many tons of ore on the dump, all of which is heavily charged with gold-bearing sulphurets, while the slate which comes from the vein at that point, as well as from the Prosperine shaft, (which is a hundred feet deep), is also highly metaline. While the assays do not go so high as some of those of the Cariboo, they are more uniform, even the slates showing well in gold, by assay. It would not in my judgment, be hazardous to prepare for and sink a good working and pumping shaft on the mine. Developments at the bottom of the 100-foot shaft, on the Prosperine mine, justify that conclusion. I consider the property valuable.

I will state, however, that in my judgment some considerable depth must be obtained before the vein will be found well in place, or so snugly encased in true walls as our California mines are usually found, and indeed I may say the same of the Cariboo; yet thousands of tons of pay-ore will be milled before the above-mentioned point is reached.

I have just had the pleasure of going to the bottom of your shaft on the Cariboo claim, which I find to be fifty feet deep from the level of the adit, making one hundred feet from the surface, or from the point where the vein crosses the surface in its course from the great blow-out toward the Lowhee creek and through the American claim.

I find the shaft has an irregular dip, but from top to bottom has an angle of about sixty-five degrees. At the bottom I was not surprised, after viewing the vein during my descent, as nothing but quartz thickly interspersed with sulphurets is visible on all sides.

I find the vein to be well encased in true walls at the bottom, except that the quartz seems to have an inclination to reach out in the hanging wall. The vein is twenty-three feet wide at the bottom and doubtless will continue to be that, or perhaps increase in width as depth is attained. I find about eight feet of the vein next to the hanging wall highly impregnated with sulphurets of the same general character as those in the ore house, which evidently came from the bottom of the shaft; also about four feet of the ore on the foot wall almost identical with that on the hanging wall, while the remaining portion of the vein

seems to be composed of white quartz, evidently of a low grade, yet containing some sulphurets. I consider the outlook extremely encouraging, and have sampled it for essays. Depth will, beyond doubt, make a great improvement in the value of the property.

I consider the selection of your mill site a very poor one, and refer you to my report to the government on that subject; also to the subject of manager, which, next to the mine, is the all important point to insure success. You will recollect that, while many gold mines pay uniformly for hundred of feet in depth, that it is extremely difficult to sample a gold mine and say what it will mill per ton, and more particularly in a sulphuret mine, as often within the space of one foot two samples may be taken, one showing traces of gold only, while the other may assay several hundred dollars per ton. I also find that even in the sulphuret ores of this district, spots will be found some distance from the surface where the showing of free-gold exceeds that which is locked up in the surrounding sulphurets. That must not lead the miner astray and cause him to think he can save the gold without concentrating, for, while such spots may frequently occur, yet all the mines so far discovered in this district are strictly gold-bearing sulphuret veins. I do not advise you as to the manner of commencing the work on your mines, as when you decide to commence operations, you will doubtless secure a practical man as manager. I remain, very respectfully,

Yours, etc.,

GEO. A. KOCH.

Our Mining and Mining Laws.

BY EUGENE COSTE, M.E.

While engaged during the last two seasons, on behalf of the Geological Survey of Canada, in the examination of several mining districts in different parts of the Dominion, I have been impressed by the unsatisfactory state of the mining industry in these districts, the unbusiness like way in which the work is carried on at most of the few mines that are being developed, the consequent immense loss to the country, and the apparent want of laws and regulations for the encouragement of real mining and the development of our great mineral wealth.

As these things forced themselves upon my attention day after day in the course of my inspection, the following questions suggested themselves: Why so little mining activity in this country so rich in mineral resources, and in which so many mining regions have long since been discovered? Why so few real mines and so meagre a production of ore? Why have so many mining schemes failed, and why, in several parts of Canada, have good mines been abandoned, which will eventually be worked again with profit? How explain that several mining districts, where splendid discoveries were made years ago, are yet comparatively unexplored, and that the true value of these districts is still unknown?

In trying to answer these questions, which concern one of the great sources of wealth for our young Dominion, I am led to the following conclusions: If our ore production is so meagre and if we have so few real mines, it is because, in the provinces of Ontario and Quebec and in the North-West territory, where the districts which I visited are situated, the laws allow speculators to purchase very cheaply large tracts of "mineral lands" which they are not compelled to work and which they hold, against the interest of the mining industry and of the country, awaiting

fabulous prices for them and so preventing *bona fide* working companies from developing them. This is evidently the reason why so many mining schemes have failed; they were only schemes of speculators trying to make a show, and with that object in view, instead of first opening the ground to ascertain its value, as a really good practical miner would have done, they have built handsome residences and villages in the woods and have done no mining for fear the indications would "play out." It is also the reason why many companies having bought, at very high figures, from these speculators, entirely unprospected mining locations, are deceived as to the value of the property, or, in case the property happens to be good, are nevertheless too poor to work it profitably after so great an outlay of capital to purchase it from the speculators. It is because these owners of "mineral lands" put extravagant values on them, and are, in consequence afraid of the truth and fear the results of complete investigations, that our mining districts remain unprospected, on the surface as well as underground, and that we cannot arrive at a knowledge of their real value.

I shall confine my remarks to the Dominion lands and the Provinces of Ontario and Quebec, where the mining districts I have visited are situated, and shall first endeavor to demonstrate how fatal to the mining industry is the system in force under existing laws and how necessary it is to abandon the custom of selling mining properties or the mining rights if the speedy development of the already known as well as the yet unknown mineral resources of the Dominion is desired. I shall further endeavor to indicate the principles which should be borne in mind in framing laws and regulations for the disposal of mineral deposits and the encouragement of mining in new countries.

A *résumé* of the laws now in force, over the Dominion lands and in the provinces of Ontario and Quebec, or at least of as much of these as concern the acquisition of the mining rights is here indispensable.

DOMINION LANDS.

The following are the mining regulations which govern the disposal of "mineral lands" other than coal lands:

Any person may explore vacant Dominion lands, either by surface or subterranean prospecting.

A mining location, except for iron, shall not exceed 40 acres, the length not being more than three times the breadth; the boundaries beneath the surface being the vertical planes in which its surface boundaries lie.

For the mining of iron, the Minister of the Interior may grant a location of 160 acres.

Having marked the location, the occupant, on paying \$5 in registering the claim, shall have the mineral right for one year.

During that year, at any time, he can purchase at the rate of \$5 per acre, cash, if he proves he has expended \$500 in actual mining operations on the claim, and if he makes a \$50 deposit, with the agent of the Government, for the survey of the claim.

For "placer" mining (gold alluvial digging) every person, holding a receipt renewable every year, can take up only one claim of about 100 feet square in the same locality, and this claim must not remain unworked more than 72 hours at a time.

A royalty of $2\frac{1}{2}$ per cent is reserved to the Crown on the sales of the products of all mines.

As regards coal mining lands:

They are periodically offered for sale by ten-

der or public auction—the lands within the "Cascade coal district" at an upset price of \$20 per acre cash, and the lands within all the other coal districts at an upset price of \$10 per acre, cash.

Not more than 320 acres shall be sold to one applicant.

Competition is invited when there is more than one applicant for the same location.

The regulations do not refer to the mining rights under lands already appropriated, or under lands which may be sold in the future not as "mineral lands," but under which mines may at any time be discovered, the mining right in these cases it is to be presumed belongs to the owner of the soil.

ONTARIO.

In the Province of Ontario we have the "General Mining Act" (Rev. Stat. 1877, ch. 29), of which the following is a *résumé*:

Any person may explore on any Crown lands not occupied.

Crown lands supposed to contain mines or minerals may be sold as mining locations, or may, when situated within any mining division, be occupied and worked as "mining claims" under "miner's licences."

The dimensions of the mining locations are 320, 160 or 80 acres. The price to purchase them is \$1.00 an acre in the territory north or north-west of the river Mattawa, lake Nipissing and the French River.

The price for the other parts of the province is not stated in the Mining Act but is, I am informed, practically the same.

The "mining claims" have an area of about one acre.

Any person possessing a "miner's licence," renewable annually for a fee of \$5, can occupy and mine one claim only at a time, on condition that it is worked within three months after the registration, and thereafter does not remain more than 15 days unworked.

The discoverer of any new mine shall be entitled to two mining claims.

QUEBEC.

In the Province of Quebec the mining rights are dealt with in the "Quebec general Mining Act of 1880" amended in 1881, 1882 and 1884.

The following is a *résumé* of the parts of this act relating to the acquisition of mining properties or mineral rights.

A licence renewable annually (fee \$2) is necessary to prospect on the vacant lands of the province.

The mining rights under all the lands of the province belong to the Crown, even for the lands appropriated before the passing of the act, except when the "lettres patentes" give in full the mining right.

The mining locations are 400 acres or less, but the Lieutenant-Governor in council may increase the limit to 800 acres.

The prices are, surface and mining rights inclusive, \$1 per acre for all minerals except gold, silver and phosphate (apatite), and for these \$2 per acre.

Every person working a gold or silver mining location must take a licence costing \$2 every three months (even if he has bought that mining location).

The owner of the surface, who desires to purchase the right of working a mine under his land, must pay per acre the difference between the rate he has already paid and the rate fixed for mineral lands and as stated above.

In case of gold and silver the "lettres patentes" will only be given after the sum of

\$200 has been expended in working the mine; two years are allowed to do this; but, after that time, if the \$200 are not expended the location may be deemed forfeited.

The Lieutenant-Governor in council may claim a royalty of $2\frac{1}{2}$ per cent on all gold and silver obtained and of 50 cts. per ton for phosphate.

The right to mine, for gold and silver, can also be acquired by licences allowing every person to take up one claim only at a time. These licences are of three kinds, *viz*:—

1. To work under appropriated lands: cost \$1 per month per miner.

2. To work under public lands: cost \$2 per month per miner.

3. To work under mining locations, granted and not being worked, or not granted: cost \$2 per three months.

The dimensions of these "claims" are: for alluvial mines about 100 feet square, and for quartz mining about one acre. They must be worked within four weeks after registration and must not thereafter remain unworked for more than 15 days at a time.

A discoverer has a right to a free licence in force for twelve months and to a claim of the largest size.

The amendments of last year (1884, ch. 22) have recognized the principle of underground rights being separated from the surface rights. They state that underground right may be bought or leased or that they may be acquired by a licence, (the owner of the surface having the first right to acquire); but, the price, the shape and the dimensions of these underground mining locations are not stated. These are to be decided by the Lieutenant-Governor in council.

In considering with attention these *résumés*, it will readily be seen that these laws give the three following results: I. A surface owner possesses or can buy first the mineral rights and is not compelled to work the mine. II. Very large tracts of "mineral lands" can be bought from the Crown lands without any obligations to develop these "mineral lands." In Quebec, however, when these lands are unworked, the Government may grant small claims over them, in the case of gold and silver, but without forfeiting for that the "deeds" of the owner. III. Rights to mine under small claims can also be acquired in certain cases by a licence.

III. The few following remarks may be offered in reference to the system of granting these small claims: it only retards the acquisition of many mines by good companies; it is the cause of a number of disputes on the question of possession of property; and, in some cases, it might cause also the entire spoiling of a good mine. These claims are very much too small and the working of the mines in these cases, being on too small a scale, is never satisfactory. There is nothing really practical in this: and it is only as applied to placer mines that it is good and useful, and this is the only case in which an individual miner can work a mine and make it pay.

I & II. But, it is desired especially, in this report to direct attention to the two first results indicated above of our existing mining laws. The backwardness of our mining industry has been a natural sequence of the recognition by the laws of these systems of giving mining rights to surface owners and of selling "mineral lands;" that alone impedes and even prevents entirely in certain districts the development of the mineral resources; and, until the mining laws are changed and another and entirely different system adopted for the acquisition of mineral

deposits, we shall have, as we have now, but few mines working.

First, indeed, prospecting is discouraged. It is evident enough that the buying up of large tracts of "mineral lands" brings that result, because prospectors are not to be found who will search on granted lands in a vast new country like ours. Surface owners, having mining rights or first rights to acquire, also discourage prospecting, because then, when a mine is found under granted lands, it does not belong to the explorer, to the man who has discovered it, but to a settler who has been working his soil for a long time perhaps, without having ever had any knowledge of the existence of this mine, or to a speculator who, as a rule, has never put his foot on the land. Nevertheless, what right, in justice, have these people to this new property which they did nothing to find and which an explorer brings to light by his exertions after long, patient and very often in this country, tedious research? Suppose it is for instance a vein 2,000 feet long with an average width of 3 feet 4 inches, dipping at a regular angle of 45°, and that the specific gravity of the ore averages 3.5. In these conditions, a simple calculation shows that the vein, being worked to the depth of 1,000 feet and under 23 acres of the surface (2,000 feet on the length of the vein, by a width of 1,000 feet on the side of the dip), will give about 1,000,000 tons of ore. If then a profit of say \$1 per ton can be made on the ore coming from that mine, it is seen that the profit to be made or the real value of the portion of the mine above the depth of 1,000 feet is \$1,000,000. Such is the fortune an explorer has discovered, that he alone indicates and creates, you may say, after perhaps many months or years of arduous tramping. Surely he ought to have some right to a portion at least of that fortune; and yet, the surface owner deprives him of it.

But, if by natural right and law, this property should not belong to the surface owner, it much more ought not to belong to him for political and economic reasons, and for the same reasons, the selling of "mineral lands" ought not to be authorized by our laws. Because, if it tends to lessen the number of discoveries, it also, as second result, prevents the development of the mines once discovered.

A vein, indeed, being discovered on the surface, one must make sure that it keeps going down, that it does not narrow until it becomes unworkable, as is often the case, that the percentage of good ore remains large enough in the vein, that the difficulties of working, due to water or other causes, will not be too great, etc., etc. All this must be known before it can be said that a good mine exists, and to ascertain this, the vein must be explored underground by shafts and levels. This is expensive work, much more so than is generally known, and it may cost many thousands of dollars, always several thousands. It is also a very difficult work, often exceedingly so, and even the best scientific and trained mining engineers sometimes make mistakes, and every mistake costs a great deal of money. Is not then an incompetent man almost certain to make a failure of it? Who is going to do that work of testing the ground? Evidently not the settler, for if he has the misfortune to try it, he will spend every year more money on small excavations sunk in all directions, than the cultivation of his land can yield him, and he never will know how to do the work, and at what results he has arrived, if he arrives at any. The district of North Hastings (Ontario) is pierced everywhere by small excavations such as I have mentioned, sunk by settlers under their lots. I

have visited many of these excavations and in most of them I failed to find a trace of ore, though they represent a large amount of time and money lost, and, many farmers neglect their farms on that account. If the farmer tries to have the work done for him, it will always be on too small scale and is in consequence doomed to failure. He will probably give the work to a so called "old miner" just arrived from California, Australia and Cornwall. This man knows it all; he will tell the farmer every night that he has done excellent work during the day, that no doubt it is a wonderful mine, that he sees an immense treasure ahead of him in the level or in the shaft, that, true, the expense has been great and nothing has yet been found, but wait, next day he will strike the lead and show him the treasure; and this goes on from day to day until the poor settler is compelled to give it up. And yet, he still believes in his wonderful mine!

It is with the same result generally that the speculator tries to work his lot, his object being only to develop it sufficiently to affect a sale.

Mining engineers and mining men supported by capitalists alone are able to take up these works of newly discovered veins underground exploring. They alone can develop that fortune discovered by the explorer. Why then are these new discoveries allowed to be or to become the property of persons who acquire them either by accident or only for speculative purposes?

If mining is a difficult matter requiring specially trained men; if it is an expensive work requiring a great deal of capital; it is also, so long as a thorough underground prospecting has not been made, a very uncertain business to go into especially in a new country where there is no comparison with neighbouring mines to be made. Mining men know that, they know that a good vein may pass at any moment to a bad one, and in consequence they will never pay, on the evidence merely of the outcrop of a vein, the enormous sums of money asked by the owners of soil. They are willing to run the chances if they have not to pay too high a price for the property; but under the present conditions, they will not try it. They will leave mining districts disheartened, not that they find the district worth nothing, on the contrary, they see there brilliant prospects, but what can they do? They find all the properties bought, all the mining rights acquired and everybody asking them enormous sums, cash, before being allowed even to explore the mine by shafts and levels. And yet this district is very little worked, and though good and discovered many years ago, nothing is to be seen there except shafts full of water and abandoned excavations, remains of the meagre efforts made by the owners of the soil and the speculators to develop their deposits just enough to make a show in order to sell the property.

I may say then, in conclusion, that it is quite necessary in the interests of our country, in the interest of our mining industry which once developed will perhaps give us the millions that our neighbours of the United States have taken out of their mines and on which is based much of their prosperity, that the mining properties should be held as national property regulated by good laws and leased permanently and directly to *bona fide* mining men, on conditions including forfeiture when sufficient work on them is not being annually done.

Why not, indeed, prevent a farmer or speculator from imposing a heavy charge on a mining company willing to run the risks of exploring and working a mine? Why, for what purpose, should the laws place between the government and the real miner, this surface owner, who, with his often primitive and exaggerated ideas of

mines, does not consider the enormous expense and the uncertainty attending the work of underground mineral exploration nor the large capital required for the subsequent regular working of a mine, and will always add to that a formidable demand for money before even allowing explorations to be made on his property; this property having been bought from the Government at \$1.00 an acre and on which he did nothing himself to discover the mine? I say a formidable sum, because I know of many instances where twenty, thirty and even one hundred thousand dollars have been refused by such owners of the surface.

The Canadian government protects many industries, often bonuses are given, the development of our agricultural resources is encouraged: why not also protect our mining industry? To day, before sale, surface rights and mining rights are the property of the country, and the country, in the interest of our mining industry, instead of giving away these rights for a few dollars an acre, should carefully guard the mining right by good legislation, because good mines are rare golden eggs which a nation must protect with great care. A large country like ours, indeed, has so many millions of acres of good lands that land speculation, though very prejudicial, can be overlooked; but, as regards mining, it is very different. Such a thing as "mineral lands" extending over large tracts of country does not really exist; and nature has been more parsimonious with mineral deposits than speculators suppose when they buy thousands of acres in a district thinking they have a mine under every lot. No! good mines, even in a very large country, are always scarce, for geological reasons (mineral deposits geologically being only accidents), for technical reasons (many deposits not being valuable because of the great difficulties of mining them or of treating the ore), for economic reasons (mineral substances being often found too far from market, or from a railway, or being in too small quantity), etc.; then, once a good mine is discovered, its permanent working by a good company should be encouraged and assured. To attain this end, the country must keep the mineral rights in its hands so as to be free, when a mineral deposit is found anywhere, to give the right to mine it to a good company, and if this right is given without charge of any sort before profit is made, it will assure those going to work every possible chance of success and it will encourage capitalists to try and develop every place where the surface indications are good, because the only money to risk will be the necessary money to test the ground. It is but just, however, that the laws should oblige these capitalists, from the day they make a profit, to suitably remunerate the original discoverer. In that way, instead of having thousands and thousands of acres of so called "mineral lands" bought* and lying for years and years unprospected, unworked and in no way profitable to anybody, we shall see on the contrary, here and there, some mines actively worked expending vast amounts in the country, bringing workmen in, creating around them villages and towns; and every one of these mines will be more benefit to the Government and to the country than thousands of granted mining locations undeveloped and not only useless from a mining point of view, but doing much damage to the other interests of the country and often to the speculators themselves.

*See "Plan of part of the North shore of Lake Superior showing Thunder and Black bays, etc.," published in Toronto, 1st August, 1883, (department of Crown Lands), and showing how much "mineral land" is taken up in that region.

As will be seen from the following suggestions which I venture to make in conclusion, nothing could be easier than to change entirely the old system of selling "mining lands" and to attain the results just stated. The national mining property would then be submitted, in its general outlines, to the same kind of administration that has been adopted: in France by the mining law of the 21st April, 1810; in Austria by that of the 23rd May, 1854; in Italy, except in the southern provinces, by the royal warrant of 29th November, 1859; in Prussia by the general mining law of 24th June, 1865; in Bavaria by the law of 20th March, 1869; in Spain by the laws of 6th July, 1859, and 13th July, 1867; in Turkey by the regulations of 3rd April, 1869; and in Greece by the laws of 1861, 1867 and 1877.

PRINCIPLES WHICH SHOULD BE FOLLOWED IN DETERMINING THE CONDITIONS UNDER WHICH MINING RIGHTS SHOULD BE ACQUIRED AND MAINTAINED.

1. Encouragement of explorations:

By recognizing and giving a right to the explorer on the mineral deposit that he discovers. This right should be in proportion to the value of that mineral deposit and consist in consequence in a certain annual royalty on the profits made out of the mine (say 5 per cent of these profits). This rent or royalty will be due every year in which profits are made by the lessee and until the death of the discoverer.

By further giving to the discoverer, if he wish, time to organize a company himself to lease and work the mine—say six months or nine months after the registration of his discovery.

2. Prevention of mere speculating and encouragement for the formation of *bona fide* working mining companies. For that purpose the mining right must be declared entirely independent of the surface right, and this mining right must not be sold, as to do so allows speculators to buy at very low figures large tracts of "mineral lands" which they retain without working them and which they sell only at very high prices; thus delaying the development of our mining industry and hindering the surface and underground explorations; and, the value of our mining districts remains unknown, which is very damaging in an immense new country like ours where the discovery of very rich mining districts may be anticipated every day.

By giving to every one offering sufficient guarantee, when a discovery has been made and when he is first to apply for it, a permanent lease (disposable and transferable as in the case of any other property) of the mining right under the area of land asked for by him, subject however to the following conditions:*

(a). The lessee shall pay to the discoverer the royalty stated above except if they can agree upon a fixed sum to be paid in the first year of the lease.

(b). To prevent the monopoly of mining rights on too large an extent of lands, larger than can be worked actively to the best interest of the country, that is to say, so as to restrict the areas under which mining rights will be leased to companies within reasonable limits, and to prevent companies from acquiring mining leases simply with the idea of speculating in or selling them at a given time, which would, like the system of to-day, ruin the mining industry:

The lessee, commencing 6 months after the day of the granting of the lease, shall pay an annual penalty of \$100 per acre of land under which the mineral substance shall not have been

during that year sufficiently worked. Every acre will be considered as insufficiently worked for which an annual average sum of \$100 shall not have been expended. This annual average expenditure will be arrived at in taking into account in the total all expenditure in any work connected with the mine; this total divided by 100 will give the number of acres of the lease sufficiently worked.

Every person having a lease will be permitted to relinquish it on demand, but so long as he retains it he will be subject to the above conditions.

If this penalty (b) is not paid within six months after becoming due the lease shall be considered forfeited.

(c). The lessee shall be entitled and obliged to buy a sufficient area of land necessary for the surface requirements of the mine (plant, offices, dumping grounds, etc.); but, no more than is absolutely necessary if the owner of the soil has no objection: the prices being the ordinary price of the Crown Lands department if on public lands, or being fixed by arbitration, at the ordinary prices of lands in that locality, if on appropriated lands.

(d). All mines shall be subject to inspection by duly appointed officers of the government so as to assure the proper working of the mine according to the conditions of the lease, the preservation of the surface—always endangered by subterranean works;—and also, the safety of mining workmen and the due enforcement of the laws and regulations respecting mines and minerals.

MINING NOTES

Nova Scotia.

The Springhill mines, says the *Herald*, continue to boom. The output has now reached 40,000 tons per month, or say at the rate of 50,000 tons a year. We take pleasure in calling the attention of the dismal-doleful organs to the fact that this is only a little less than the total output of Nova Scotia mines a few years ago. The output at Springhill is only limited by the existing capacity to supply.

Some very interesting facts regarding the Londonderry Iron Mines, their failure, and its causes, may be gleaned from the following excerpt taken from a very able review of our iron industry given by the *Montreal Star*:—

In the forests of the Cobequid Hills, in the Province of Nova Scotia, miles away from any road or settlement, a vein of iron ore was years ago discovered. Geologists visited the locality and pronounced the deposits of great extent, and a grant of land was obtained from the Government. A Catalan forge was built in 1850, and three years later a small blast furnace was put up, charcoal in both cases was used as fuel, the trees from the forest around being made into charcoal. A small stream ran past the iron mine and was made to drive the blast engine. The iron ore was very pure, so the pig iron made was of superior quality; there was no home market, but it was exported to England, although the iron had to be carted to the nearest shipping point, namely Great Village, six miles away from the furnace, and situated at the entrance to a small tidal river on the Cobequid branch of the Bay of Fundy. Navigation on the upper end

of the Bay of Fundy is dangerous; the tides which here rise to the height of 71 feet, rush in and out with great rapidity; the river could only be entered at high tide by vessels drawing not more than 12 feet of water, and the navigation to the entrance of the river was bad. The construction of the Intercolonial Railway, which eventually was brought within three miles of the furnace (at the expense of permanently lengthening the main line by five miles, and unfavorably affecting the gradients and curvature) made the place more accessible. It was still only a little hamlet in the midst of the forest, but it was self-contained, having plenty of ore and timber for making charcoal. There was a demand for the iron, as owing to its superiority the English War office, upon the recommendation of Sir William Fairbairn and others, were using it for the manufacture of ordnance. This was before the age of steel, and, no doubt, the iron commanded a large price, and, altogether, the works were remunerative to their owners.

In 1873, the Acadia Iron Mines, as they were then called, were purchased by a company of a few English capitalists having Sir William Siemens at their head with a capital of two and a half million dollars. Their intention was to make steel directly out of iron ore by a new patented process, invented by Sir William Siemens and also to make coke, pig iron, etc. This the Steel Company of Canada, had its headquarters in England, and managed the Londonderry business from there. They paid 40,000 in cash and \$60,000 in paid up stock for the Acadia Iron Mines, also \$40,000 for the patent rights, a total of \$1,040,000.

The accidental location of the little charcoal blast furnace seems to have given rise to the choice of the situation for the new works. It would be difficult to account for the selection in any other way. Works specially designed for the new patented process, with rotators, melting furnaces with a regenerative gas producers, two blast furnaces, branch railways to the Intercolonial Railway, and the different ore mines, houses, buildings, etc., etc., were built. The scale on which the expenditures were made can best be understood by reference to the item of cost for the manager's house, which came to \$40,000.

The works were completed and got into operation probably at a further expenditure of about \$1,250,000. The new process did not seem to do very well, and after costly experiments and repeated trials, it eventually proved here, as elsewhere, a complete failure. Hundreds, perhaps thousands, of tons of expensive machinery had to be broken up, and the melting furnaces and regenerative gas producers were pulled down. A second-hand rolling mill was purchased and some puddling furnaces built, an axle forge with a foundry for car wheels an general castings added, and the product of the works changed from steel to pig iron, bar iron and castings. The place was not now self-contained as before; charcoal was no longer the fuel used, so the trees were of little use, except for timbers in the iron mines. What was wanted was coal and coke, and although at the time of the purchase, coal was supposed to be on the property, it has never yet been actually discovered. The coal field of Pictou is 51 miles to the eastward, that of Cumberland, 43 miles to the westward. Limestone in considerable quantities is required and is obtained from Brookfield, 25 miles to the eastward. When, after having paid freight on all these materials, iron is made out of them, there is no outlet but by the same Intercolonial railway, the distance by rail to Montreal being 773 miles.

*That would place a lessee on the same footing as an owner in fee simply would be, excepting the condition of working the property necessary to prevent speculation.

The condition of affairs was bad enough but the situation was made much worse by the fact that the company had never built any coke ovens of their own, and that at this time only one colliery mined a coal suitable for coking, and also owned the only coke ovens in the country, they consequently supplied coke at their own price, helping materially to kill the goose which laid the golden egg. One day an explosion took place in this particular mine, set the mine on fire, and closed it. It has been closed ever since. For a time coke was not to be had for the iron mines at any price, the blast furnaces had to be shut down, and the loss from this cause alone can be better imagined than described. After this experience some coke ovens were built, and to some extent this has made the company independent, finally a coal mine was purchased and fully equipped, but upon practical trials, the coal was found to be to some considerable extent unfitted for their uses. It was also discovered that owing to an arrangement to have their iron ore mined by contract, that the contractor had made money for himself but had permanently ruined one of the iron mines.

Instead of running a general store from which a considerable revenue would accrue, some outsider was granted the privilege and took advantage of it.

Is it surprising that after all these vicissitudes and bearing in mind the fact that until 1880 imported pig iron was admitted free of duty into Canada, that the company failed. It is more to be wondered at that they struggled on as long as they did.

In 1880 an import duty of \$2 per ton was imposed, and in 1883 a bounty of \$1.50 per ton of pig iron manufactured out of Canadian ore, was granted by the Dominion Government. Under these improved conditions, the company's operations were continued by the liquidators. It is to be hoped that a re-organization will be effected, the management centred in Canada, and the enterprise made productive to the proprietors and the country at large. Under a careful management, there can be no question that a satisfactory dividend can be earned, upon the expenditure of the works as they stand.

It is manifestly unfair to condemn every projected iron making enterprise in Canada, simply because in the past this particular case has not succeeded. In spite of all their troubles the pig iron, bar iron and other products of the London-derry works have been of a very superior quality and have always commanded the highest price in the market.

Quebec.

An assay of the ore taken from the Belvédère deposit, in the vicinity of Sherbrooke, has been made by Mr. Hoffman, of the Geological Survey, and is reported to give 28.29 per cent. of metallic iron.

An exchange says the lead mining property on Chatt's Island, owned by Captains Cowley and Murphy, was last week sold to Mr. James Robertson of the Montreal Lead Works. Mr. Robertson intends to have the land surveyed into small sections and placed upon the European market without delay. The property contains nearly one thousand acres.

We understand that Mr. F. Stacy Shirley has been appointed manager to the Du Lievre Milling and Mining Company, at Bassin du Lievre, vice Mr. Geo. H. Bacon, resigned. This company, which has been frequently erroneously referred to as Messrs. Bacon & Co., own the Lievre phosphate property, and we learn that the

investors are now taking hold of the mine, and commence active operations at it as soon as the weather will permit them doing so profitably.

Messrs. G. H. Nicholson & Co., of New York, proprietors of the Albert mines, have purchased from the Eastern Townships Bank, together with all the movables, the Hartford and Capel mines. This property was owned and worked for many years by the Canadian Copper and Sulphur Co., Limited, but owing to financial difficulties they were obliged to close down some two years ago and the property was all acquired by the Eastern Townships Bank at sheriff's sale. The new owners will resume operations in the above mines at an early date.

Ontario.

The London correspondent of the *Montreal Gazette*, mentions two important assays of Canadian minerals having been made, one from the Sudbury copper mines, the other specimen was argentiferous lead ore from the mines of Mr. Edward Wright, situated at Lake Temiscamingue. It was found by dry assay, to contain of lead (metallic) 52 per cent of silver 13 oz. 14 dwts. 10 grs., per ton of ore of 2,240 lbs., or of silver 26 oz. 7 dwts. and 21 grs. per ton of lead of 2,240 lbs. This latter property is now connected with the Canadian Pacific railway by water and by tramway, and it is expected to prove of considerable value.

THUNDER BAY DISTRICT.

Work has been suspended for the present at the Elgin mine.

It is understood that negotiations for the sale of Silver Mountain West End property will soon be concluded.

An air compressor, capable of driving three drills, is in course of erection at the East End Silver Mountain mine.

The shaft at the Partridge Rock Silver Mine is now down about thirty feet. The indications for silver are reported to be most encouraging.

The *Miner* reports that a big strike of rich ore has been made at the Beaver mine. It has been made in the drift, beyond the shaft about 150 feet, and is of almost unexampled richness. About 350 pounds of ore have been brought into town which will assay from 1,000 to 2,000 oz. to the ton. The vein has been laid bare for about 18 feet of its depth and for about 400 feet long; it shows now 7 feet wide, and is uniformly as good as the samples all the way across.

The following are the directors of "The Consolidated Huronian Gold Mining Company of Ontario":—Horace J. Neville, G. A. Thompson and Alexander McEwan, of London, England; A. R. Gray, Edinburgh, Scotland; James McLaren, Buckingham, Quebec; J. A. Keefer, Port Arthur; and N. Kingsmills and A. J. Cathanact, Toronto. The capital stock is \$1,300,000, with an additional working capital of \$500,000. The head office of the new company will be at Port Arthur.

Manitoba and North-West Territories.

A member of the Geological Survey staff who has been engaged during the past season in the work of investigating the coal deposits of the Saskatchewan region states that the coal supply of the North-West is absolutely inexhaustible, and

that the whole district lying between Rocky Mountain House and Fort Pitt is one vast series of coal beds, both hard and soft, of the very best quality.

In the last Canada Gazette notice is given that Duncan McArthur, W. R. Allan, F. A. Fairchild, R. D. Bathgate, Archibald Wright and C. W. Betts, all of Winnipeg, apply to the Governor-in-Council for letters patent incorporating such applicants a body corporate and politic under the corporate name of "The Rocky Mountain Mining and Lumbering Company (Limited)," for the purpose of carrying on a mining and lumbering business within the Dominion of Canada, also for the purpose of said company, to build, equip and operate tramways, sailing and steam vessels for the carriage of lumber, timber, minerals or mineral ores or any other production by said company; to purchase, build and erect stamp mills, saw and planing mills, or any one or more thereof. The head office of the company will be at the City of Winnipeg.

Work is being actively pursued at the Saskatchewan coal mine. Some difficulty has been experienced owing to the scarcity of miners. The Hungarians who had been employed were found to be worthless, and had to be discharged, and operations are now being carried on by miners imported from Nova Scotia, who are working on a percentage. The present staff employed is 71 men and the daily output is 75 tons. The capacity of the mining machinery is 260 tons per diem, and as soon as the management can place their full staff to work, this is expected to be their daily output. Mr. W. M. Caldwell, of the firm of Caldwell & Keenan, under whose superintendence the work of development is being carried on, states that when they began work the mine had been neglected for about eighteen months, and it was covered with water to the depth of from 16 to 18 inches. The old company sank their shafts at the base of the hill under which the mine is, and did not work more than from twenty to thirty-five feet of cover. He had, however, run two shafts right under the hill and they are now working under a cover of two and three hundred feet. So far the shafts have run in 370 feet, and they are steadily going forward. He states that as they get deeper and deeper into the earth the coal continues to improve in quality.

British Columbia.

Mining operations in the Kootenay district have been suspended for the winter.

In another column is given a copy of Mr. G. A. Koch's report to the directors upon the mining property belonging to the British Columbia Milling and Mining Company.

A quartz nugget taken from Granite creek was recently sold to Mr. I. B. Fisher, of the Bank of British Columbia, New Westminster. It weighed 34 ounces, and after allowing 40% for quartz, is valued at \$340.00.

Work has been begun by awarding the contract for grading the site of the shaft house, and sinking 50 feet on the vein from the surface, to connect the present blind shaft, which is down fifty feet from the end of the tunnel, developing the vein 105 feet from the surface, where it crosses in the ledge, showing a vein of 23 feet in width between walls.

This Company, says the *Colonist*, was organized in 1878, during the quartz mining excitement, secured several locations on the Bonanza lode in Cariboo, near William's creek, and laid down at a cost of some \$75,000 a complete twenty stamp mill, rock crusher and sawmill. After the general collapse, which occurred in the fall of that year, caused by an undue inflation of mining stocks before any development had actually commenced, the company, feeling that further assessments upon the stockholders would be fatal to the interest of the enterprise, decided upon shutting down, preserving their machinery, and protecting their claims for further operations, when a more propitious state of mining affairs would warrant development, the directors and shareholders having every confidence in the value of their property and the ultimate success of the enterprise. The Directors of the Company, which possesses 4,500 feet on the Bonanza vein, known as the St. Laurent, American and Cariboo claims, and 1,500 feet on the Wilkinson, are: President, Mr. Joseph Heywood; Secretary, Mr. Geo. A. Sargison; and Messrs. J. H. Todd, J. H. Turner, C. E. Redfern, I. Oppenheimer, and Frank Barnard.

The amount of force exerted by heat and cold in expansion and contraction of metal, is equal to that which would be required to stretch or compress it to the same extent by mechanical means.

MINING REGULATIONS

To Govern the Disposal of

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

RED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contain the forms to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

A. M. BURGESS,

Deputy Minister of the Interior.

The Intercolonial Rail- way of Canada, AND FREIGHT ROUTE BETWEEN Canada and Great Britain

—AND THE—

Direct Route between the West and all points on the Lower St. Lawrence and Baie des Charleux, also New Brunswick, Nova Scotia, Prince Edward Island, Cape Breton, Newfoundland, Bermuda and Jamaica.

New and Elegant Buffet Sleeping and day cars run on through Express trains.

Passengers for Great Britain or the Continent, by leaving Toronto at 8.30 a.m. train, Thursday, will join outward Mail Steamer at Halifax a.m. Saturday.

Superior Elevator, Warehouse and Dock accommodation at Halifax for shipment of grain and general merchandise.

Years of experience have proved the Intercolonial in connection with Steamship lines to and from London, Liverpool and Glasgow to Halifax, to be the quickest freight route between Canada and Great Britain.

At this quarry there is an inexhaustible supply of most beautiful White Marble. Samples to be seen and information obtained at the office of the MINING REVIEW.

DEPARTMENT OF INLAND REVENUE.

An Act respecting Agricultural Fertilizers.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that such jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale, any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells, or offers or exposes for sale, any fertilizer which does not contain the percentage of constituents mentioned in the manufacturers' certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

F. MIAL,

Commissioner.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office until noon on Monday, the 1st day of November next, for four timber berths of ten square miles each, more or less, numbered respectively 4, 5, 8 and 9, situated on Kicking Horse River and Ottentail Creek, a tributary of the Kicking Horse River, near Field and Ottentail Stations, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately of these berths, together with the conditions on which they will be licensed, may be obtained at this Department or at the Crown Timber Offices, Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

A. M. BURGESS,

Deputy of the
Minister of the Interior.

Department of the Interior,
Ottawa, 14th August, 1886.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office up to noon on Wednesday, the 1st day of December next for three timber berths of fifty square miles each, more or less, numbered respectively 16, 17 and 18, situated on the west side of the Columbia River, near Golden City Station, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately of these berths, together with the conditions upon which they will be licensed, and the forms of tender therefor, may be obtained at this Department or at the Crown Timber Offices at Winnipeg, Calgary, N.W.T., and New Westminster, British Columbia.

OFFICE:

UNION CHAMBERS, 14 Metcalfe Street.

The CANADIAN MINING REVIEW is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts as well as others interested in Canadian Mineral Lands are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

TO SUBSCRIBERS.

Through an unfortunate and unforeseen accident the printing of the January issue of the REVIEW was so delayed as to entail the publication of a double number absolutely necessary. The present issue has therefore been increased to sixteen pages.

The Development of the Mines of the Ottawa Region.

(By James Stewart, Ottawa.)

Written for the Canadian Mining Review.

The mineral district of which Ottawa is the centre is a large one, including the western part of Quebec Province and the eastern part of the Province of Ontario, and it is to this section especially that reference is made, although the following remarks apply to the whole of the provinces mentioned, the one under Grit, and the other under Tory rule, and as regards the best interests of the miner, prospector or explorer, the saying, "good and bad everywhere," may be put "bad and worse," applies equally to them both.

The development of the mines has an important connection, with the most complete knowledge of the minerals of scientific interest only; and for this reason, and that of the injustice done to one section of the population, by those in power, is the apology offered for these remarks, which may appear to some to have too much of a technical bearing.

About two years ago, when some of these notes were made, there appeared in the news-

papers of almost all parts of Canada articles and correspondence under sundry headings, showing clearly that there is something materially wrong with the mining interest of these provinces as at present situated, that is, an individual ownership instead of Government holding the minerals for rental, or on lease.

Some writers attribute the lack of mineral development and stagnation of the whole industry (coal mining excepted) to the absence of a Bureau of Mining Statistics, or a neglect on the part of the Geological Survey of Canada in not publishing reports of the extent of mining done each year. In making this discovery they at once saddle the Geological Survey with the total neglect of the mining interests, and find relief in considering it the "Scape Goat" in this case, and none tried to arrive at a clear understanding of the position in which the mining interests of the provinces stand at the present time. Had statistics been collected by the Survey they would tend to make more glaring the error in our laws as regards mining lands; the number and acreage of our mining land monopolies, and show more clearly the error our Provincial Legislators have fallen into in selling the minerals with the surface soil to the farmers; it is desired to point this out as the true cause of the lack of mineral development in this district and suggest a remedy.

Others gave the cause as depending on a foreign market for our ores, and extravagance and bad management, with an ill advised expenditure on the surface, of too much money before the mine was developed in depth, and some to untrue and glowing promises, of "millions of tons of ore in sight" on the part of promoters of a new enterprise. There is no doubt, in some cases, these causes have helped to close the enterprise and deter others from embarking in a similar mine or property.

In Nova Scotia, Newfoundland and British Columbia, the Crown or Provincial Government owns the minerals, and issue licences to parties desiring to open and work mines, and in these Provinces, is the business of mining largely and most successfully carried on. While in Quebec and Ontario the minerals are at present sold along with the soil, and in doing so, the birth right and portion of the explorer, prospector, or miner, is given to the farmer, or still worse to the speculator in mining lands, and these sons of toil, have to beg for terms from the miserly farmer, or independent and extortionate land owner or speculator. Mining lands have been sold in this way, during the last 40 or 50 years in Quebec and Ontario; some few it is true are being worked, but the great majority of the most valuable mining lands and mines are in the hands of speculators, or parties who will not work them, and ask for the mines and properties an exorbitant price should an intending purchaser approach them.

This state of affairs, or the act of the Local Legislators selling the minerals, instead of giving a lease or licence, compelling the owner to work

the mine or quarry or it would revert to the Government, or by exacting a low rent or royalty under such a lease or licence, from the profits derived from working the mine, is the cause of so many valuable properties being locked up, as it were, and development retarded, and the mining industry does not receive the attention it would, if these mining lands remained in the hands of the Government. In proof of this may be mentioned the vast amount of mineral land held by companies and speculators in the Lake district, also in Eastern Ontario, and amounting in many cases to thousands of acres in a block, thereby binding the settlement of the country. In Eastern Ontario, alone the amount thus held amounts to many millions of acres of the best mineral lands. The same is true also as regards the Phosphate region in Quebec. It is this system of unconditional sale of mining lands for speculation, without regard to yearly working, that has ruined the mining interests of this district. The error of anyone party owning a large extent of mining land in a block, arises from the fact, which is well known to experienced miners and explorers, that minerals do not occur by chance (but this subject is too large to be considered at present), that is, certain rocks hold certain minerals, and by selling, say to an Iron Mining Company, a few thousand acres in a block, they got other minerals, which they cannot treat or the use of which they may not know, and the ores other than iron remain unworked.

Compare the system adopted in the Western United States, where a mining claim is given to the discoverer on condition that it is worked, or labor spent on it to the extent of \$100 each year, or it will revert to the Government. Under that system the right of discovery of the explorer, prospector, or miner, is respected, and a reward granted him (he can locate two claims), but in Ontario and Quebec, he has no rights, and he is, therefore, drawn to the more inviting fields of the United States. The location of the claim in the States is made by the discoverer on the ground, and placed on record in the Land office, but in this district it is made by a clerk in the Land Office, and not by the discoverer, a practice which has proved fruitful of the worst abuses and frauds on Canadian discovery. In the United States, in granting mining claims in that way, ore accumulated through the compulsory clause to work it, at least so much each and every year, and from its accumulation arose the necessity for milling or smelting works to work it up, and had the same inducements and compulsion been in force in Canada, our mines would have been counted by the thousand, instead of the few now in operation.

The chief ores of this region are: iron, (hematites and magnetic), phosphate, or apatite, and a large variety of pyrites, or sulphuret ores of the miners, holding in places copper, gold and silver in workable quantities, lead or galena, plumbago (black-lead), mica, and others of less importance.

The ores of iron are found in such variety and

abundance that the only reason they are not now worked is the question of cheap fuel for reduction. Next spring certain tests of machinery are to be made, and should they prove as successful as former trials, this question will be settled on a commercial scale, and the smelting of iron established in the district.

The apatite, in the raw state, is largely shipped to Europe, but home demand, or the super-phosphate of lime for fertilizing purposes, can be supplied from the works of the Brockville Chemical and Superphosphate Co. (Limited). The pyrites used by this company for the last few years, for the manufacture of sulphuric acid, has been imported from New York State, but ores from the County of Hastings have been introduced to them, and the supply in future will be procured from local ores. The extended mining of the pyrites ore of the district is a question of much importance to the city of Ottawa with the cheap water power for dressing ores, and grinding apatite, as the sulphur is used for treating the apatite in the form of sulphuric acid, and would form an important industry, if all we exported was shipped as superphosphate of lime, and the residue of the pyrites ore can be most successfully treated after roasting, along with the lead ores, which we also have, and the copper, gold and silver extracted. Our lead ores are too poor in silver (about 5 oz. or \$5 per ton silver) to pay to work for silver and lead alone, but when smelted along with the residue of the sulphur ores, holding copper, gold and silver, the question of working both is settled.

The more extended production of gold also requires attention. No man has ever possessed too much of it, and no country produced too much. Its value increases with the cost of getting it, and the want of it. It is our highest standard of money and exchange, and is therefore the best investment for *surplus* labor and capital, when found in workable quantities. The discovery of gold in California and Australia produced periods of great world wide prosperity. All classes and conditions of men were drawn to a new occupation and country by the high wages earned in the mines. A laborer who had been working for a farmer or tradesman, for \$1.00 or \$1.50 a day, could wash out gold to the value of \$10 or \$20 a day. Can a wise adjustment of our mining laws be made to have this effect, if only on a much smaller scale, by granting free great-mining claims in districts where gold is known to exist?

In iron alone, had such measures been adopted, there would to-day have been enough mined and worked to supply our own wants and for exportation, as is done in Sweden and Norway with similar ores, climate and fuel (wood charcoal), as the laws of that country are such that no mining property may remain idle so long as any one desires to work it. In Sweden and Norway a party owning a mine and not working it, another party can do so by paying the owner half the profit of the working of the mine, and if he gives it up the owner or any other person can under-

take to work it on the same conditions, hence no mining properties remain unworked.

In most European countries, and in some parts of the British Islands, the minerals are owned by the Crown, and at one time, even in Ontario, certain reserves of minerals were made in old deeds, but of recent years this is not the case.

Some may say, in advocating the State owning the land, you are advocating communistic doctrines, but that is another question altogether; what is desired is the State to own the minerals, and is British law and custom, and that is advocated "by George."

There are at the present time thousands of British and Canadian subjects in the United States mining regions who would take up claims in Canada were the laws such as would induce them to do so, but at the present time there is no free grant mining claims given, or compulsion to work on owners, and no inducement offered to explorers, prospectors or miners, to locate and develop a claim, unless stealing one's discovery is considered such by those in power, and that act is best described in the words of Shakespeare:

"You take my life,
"When you do take the means whereby I live."

Under the present system 100 acres realizes to the government, say at \$1.00 per acre, \$100; and in 10 years the country gets the benefit of the amount expended on that mine, in labor, &c., if it is developed and worked, but if not, nothing. While under the system where the government holds the minerals, and gives free grants to Miners, or on lease, or royalty, the country receives at least \$100 per year, for the 10 years say \$1,000, less the value of the 100 acres—\$100, leaving a balance of \$900 in favor of the free grant or lease systems.

The country receives from sale at a two years' purchase:			
Dr.			Cr.
To 100 acres @		By Cash	\$100 00
\$1	\$100 00	No work in 10	
		years	000 00
	\$100 00		\$100 00

The country receives from free grant, at a ten years' term:			
Dr.			Cr.
100 acres @ \$1.	\$100 00	By 10 years	
Actual benefit received by the country in favor of free grant	900 00	work @ \$100	\$1,000 00
	\$1,000 00		\$1,000 00

And under the lease or royalty system, in 10 years the country receives the same as under free grant, together with the additional royalty received when the mine is paying, which may be several thousands of dollars yearly, and increased value of public lands.

But it may be asked, from what source will the government receive revenue, for inspection and office expenses, if they do not sell the lands as at present?

The free grants which proved paying mines, on arriving at that stage, a low royalty is charged on profit, after working expenses are paid, would yield annually a large revenue to the government, than the present system of selling lots.

In proof of this, the British Crown paid the Earl of Derby £50,000 stg. for the Isle of Man, and has been refunded from royalty on mines and quarries, more than the sum paid for the island.

This compulsory working to hold a claim may be considered a small thing in an individual case, as regards the amount of labor employed, but take the returns for a province, or the whole Dominion, and it would amount to a large sum, on all the now known valuable mineral lots throughout Canada.

In thus yearly doing a little on a mining property to hold it, new discoveries would be made, and new life given to what was possibly considered a doubtful prospect. It was in that manner that John W. McKay and other United States millionaires gained their first start; through being compelled to work their claims they made a discovery, which enabled them to sell or work it with profit. The mining interests in Canada will never prosper till similar measures are adopted.

The custom of granting land to farmers under the free grant system, and not giving an explorer, prospector, or miner a free grant, under conditions similar to that of the farmer, or compulsory development of the minerals contained in the property, is an injustice to the mining section of the population, and for that reason settlement has made progress and mining has not.

Some parties argue "but why give away a valuable mine as a free grant?" Ans.—A mining property in this section has no more value than the same amount of land, say \$1.00 an acre, which you now give to the farmer. The miner would return \$100 in labor each year, and develop the mine and prove its value, and if it proved such the Government would receive a revenue from royalty as long as it paid expenses. And some say: "What use would a free grant be to a miner who had not money enough to purchase it at \$1.00 per acre?" Under the free grant plan both the farmer and the miner have energy and skill to develop the value of their claims, with proper provisions imposing on them a certain amount of work yearly, and that is worth more to the country than so many dollars paid into the land office, and the property lie in a state of nature and undeveloped.

There is a wrong system practised in Ontario and Quebec, in selling mining lands by auction. When a valuable ore has been discovered in a section of country the excitement gets strong, and the land office is flooded with applications for lots, and to satisfy, not the discoverer, but contending parties, the properties are advertised and sold by auction, and the competition raises the price beyond that which a miner can afford to pay (the discoverer is not rewarded), and the property falls into the hands of a more wealthy man; but a speculator, who will not work it himself, but purchases it on a speculation of a rise in value, which fails to come, and the properties so sold remain undeveloped. The district ought to be opened as a free grant mining camp, and the properties would be developed under proper

mining laws and inspection, and the country receive many times more benefit than by selling it unconditionally.

A certain Ontario newspaper for the last few years has sent round a reporter to the various mining settlements, whose principal business is to write a description of the mines visited, but more after the style of an election dodge, or blind, to show the splendid development under the present system of management of the Ontario Land Office, but failed to see, even through "spectacles," the much needed "reform" of the mining laws and "reformation of the land office and the number of Grit mining land monopolies in Ontario. If the location of a claim was made by the discoverer *on the ground* (as is done in the Western States), he would not be at the mercy of interested parties, who manipulate the land office for their own purpose.

The vast importance to a country of the proper development of its mineral wealth, renders this subject one requiring the attention and careful consideration of our legislators and citizens.

Precise Geological Position of *Siphonotreta Scotica*.

NOTES ON AND THE PRECISE GEOLOGICAL HORIZON OF SIPHONOTRETA SCOTICA (DAV.)

Written by Henry M. Ami of the Field Naturalists' Club.

At the Montreal meeting of the A. A. A. Sc. in 1883, Mr. J. F. Whiteaves, of the Geological Survey office, read a communication or paper in which there was then recorded for the first time the occurrence of a beautifully fringed or spinose shell which Dr. Thomas Davidson had recognised as the Scottish species, to which he had given the designation *Siphonotreta Scotica*. The specimens referred to in that paper had been collected by Mr. Watts, of our club, who handed them over to Mr. Whiteaves for determination, and through the generosity of Mr. Watts, the specimens in question have been presented to the National Museum, and may now be seen in the cases of the Geological Museum at any time.

These specimens had been obtained from blocks of impure limestone about Mr. Watts' residence near Cummings' bridge, and were said to have come from a well which was sunk on the same property. There was but little doubt from the lithological aspect of the rock, as well as from the few associated species then obtained likewise, that the species was referable to the Utica formation. That such was the case will be clearly seen from recent investigations made with that object in view. As has already been noted on previous occasions, the upper members of the Trenton formation consist in impure argillaceous or clayey limestones, inter-stratified with more or less thin bands of shales, whilst the lowest beds of the overlying Utica formation are themselves not only characterized by shales, as most of the formation is in general, but contain also bands of impure limestone. These bands of impure limestone of the Utica—the lower measures of that formation—are well exposed on either side of the Rideau River, in the vicinity of the Rifle Range, and it is in one of these bands that the beautiful little brachiopod in question is to be found. The precise one in which it occurs in tolerable abundance is in that band which, crossing the river from side to side of the rapids, in line with the targets of the

ranges, gives the peculiar orographic aspect to that portion of the river, and form the head of the rapids or little fall, above which, and as far as Hurdman's Bridge, the river flows quite smoothly. From this easily recognised and accessible band, a number of other members of the club have, besides the writer, had the pleasure of finding several specimens or individuals of this species. As far as we are aware this is the first time that this species has been recorded to have been found *in situ* in this country, and it may be found at any time by any member of the club. There are numerous points as yet to be investigated with regard to the affinities of this species; even its generic relations are not all exactly defined, and there is wanting evidence wherewith to describe its internal structure.

Dr. Davidson and Dr. Schmidt agree that the genus is allied to a *Lingula* and belongs to Prof. King's sub-division *Tretenterata*. The mode of preservation of the Canadian specimens, its phosphatic (?) character show its affinities to be as above. In examining the zone of this species, the following notes were obtained on the stratigraphy of the rocks at that place.

The following is a section obtained on the spot and given in ascending order:—

1. Lower bed of section, which is, no doubt, close to the line of contact between the Trenton and Utica formations, is an irregular, uneven bed of impure nodular limestone somewhat bituminous and holds fragments of *Orthoceras*. This is followed by another similar band of impure limestone which, in its turn, is overlaid by dark brownish black bituminous and very brittle, shaly beds.

Two bands of limestone interstratified with friable shales then occur, upon which rest bituminous and impure shales, holding *Asaphus Canadensis* and other fossils over which the *Siphonotreta* band occurs.

This band marks a special zone in this formation, and from it no less than sixteen species of fossils have already been obtained, and more will no doubt be obtained after further detailed examination is carried on. The following is the list of species:—

Lingula curta—Hall.
Lingula elongata—Hall.
Lingula quadrata—Eichwald.
Siphonotreta Scotica—Davidson.
Orthio testudinaria—Dalman.
Strophomena alternata—Conrad.
Leptæna sericea—Sowerby.
Zygospira Headi—Billings. (*typical*).
Zygospira modesta—Say.
Zygospira (*probably new variety*).
Conularia Trentonensis—Hall.
Asaphus Canadensis—Chapman.
Asaphus megistos (Locke), or *platycephalus* (Stokes).
Calymene senaria—Conrad.
Beyrichia oculifera—Hall.
Leperditia cylindrica—Hall.

From these it would then follow that the age of the rocks in question is as near as it can be laid down at the base of the Utica formation not far from the top of the Trenton formation.

On a single specimen of shale there occur the following species:—

Siphonotreta Scotica—Davidson.
Leptæna sericea—Sowerby.
Zygospira Headi—Billings.
Asaphus Canadensis—Chapman.

This association is a very interesting one and worthy to be put on record. Numerous crinoidal fragments also occur with the above species, and in the debris of the shales the typical *Triathrus Becki* was found to occur there, and it is not inserted in the list as it was not found *in situ*.

Every species mentioned in the above list was carefully collected in the same band in which the *Siphonotreta* occurs, so that its exact stratigraphical and palæontological relations are now pretty well known. There remains, however, much to be done in ascertaining the internal character of this species, which, in Scotland, characterises the Llandeilo formation of rocks of Ayrshire, where it was discovered by Mrs. R. Gray at Craighead.

Should any member of the club find any specimens showing either muscular or vascular impressions in the interior of the shell, or other internal characters, it would be conferring a benefit to science to contribute the same in the club's transactions or some similar medium of publication.

Some Economies in Iron Manufacture.

By Alex. E. Tucker, F.C.S.

I have been led to choose this subject for the paper which I have the pleasure of reading to-night for more than one reason, for it seemed to me there are continuing defects in ordinary puddling which may be lessened if they cannot be altogether prevented. I am aware that several excellent papers have been read before this institute on matters more or less connected with puddling, and I therefore hesitated in bringing the subject again before you. Since, however, those papers were read the development of the process known as the Basic-Bessemer and Basic-Siemens processes for the manufacture of steel, with which for some time I have been associated, has thrown considerable light on the practical chemistry of puddling, and although it would be entirely out of place for me to enter into any one of the questions raised as to the exact chemistry of any of these manufactures, yet an attempt at a general application to the subject of puddling of what we now know respecting soft steel making, seemed to me eminently suited to the circumstances in which puddling is at present placed.

I propose to borrow some facts which chemistry has brought out in the development of steel making, and to try to apply them to iron making.

If my judgments in the matter are not in agreement with the more extended practical experience of those gentlemen immediately concerned, I trust our evening will not have been unprofitably spent in discussing the points which I shall raise.

I shall in the foregoing remarks, speak at some length of the relations which chemistry has developed in respect to iron and steel making, and I may premise that it seems to me somewhat remarkable that scientific treatment has so seldom been observed in the art of puddling, because the reactions of puddling are entirely chemical, and although we must confess to ignorance on many of its problems, yet we have a general grasp of the whole subject, and the chemistry which has ensured economies and successes in the spring time, as it were, of steel making has been available in the autumn of iron manufacture.

In treating the subject from this point of view, I am most anxious to avoid any unnecessary chemistry. I feel it would be entirely out of place, and I hope that the wish of your secretary, who enjoined me to treat the matter as practically as I could, may be fulfilled.

I do not wish to suggest that analyses of the materials used and of the products obtained would ever have done for puddled iron what it has done for steel: that is impossible. We must bow to the magnificence of those developments

which have culminated in the possibility of producing 500 tons of steel from two Bessemer converters in 12 hours, but I do not hesitate to say that economies may be effected by knowing more exactly the composition of materials operated on, and the physical and chemical conditions under which the impurities of the pig may best be removed, and it is with such economies that I propose to deal.

The practical process of puddling from a chemical point of view is extremely simple, and consist, as is well-known, in the absorption of silicon, sulphur, phosphorous and manganese contained in the pig iron by the oxide of iron used in the fettling, and in the removal of the carbon by its reduction of the fettling to matallic iron. We have, therefore, a debit and credit account—there is a loss in weight due to the removal of the bodies I have named, and there is a gain in weight due to the production of metallic iron from the fettling. The same removals take place in the basic process, but there is no gain in weight from reduction of oxide of iron, as instead of oxide of iron being used for the lining or fettling of steel making apparatus it is found better principally on account of the great heat developed, to substitute a variety of lime. This point of departure leads to an important matter in economy, of which I shall presently speak at more length. In addition to these differences in the two apparatus, there is the important one that while in the puddling process the whole of silicon, phosphorus, sulphur, carbon and manganese are burnt by the oxide of iron, in the case of steel they are mostly burnt by the air blown through the liquid metal.

Now, leaving these well-known facts it will, on a moment's consideration, be obvious that there must be a certain percentage of these bodies silicon, phosphorus, sulphur and manganese which is best adapted for the particular process concerned. In the case of steel this percentage is that which is just enough to produce the requisite amount of heat to keep the bath of metal sufficiently fluid—you will recollect that there is no fuel used beyond that in the metal itself—any excess of this percentage of course means waste, and any deficiency means waste on account of cold and, therefore, skulls, etc.

It will, therefore, be profitable to consider in what way any excess or deficiency of the elements named affect the quantity and quality of the resulting iron, I will just glance at all of them, but it will be well to bear in mind that it is the percentage of silicon and phosphorus which practically decide the merits of forge pig. Take a single case, and let us suppose that the best possible result in puddling in a given furnace is obtained with an iron or mixture of irons giving a percentage composition of:

	Per cent.
Silicon	1.50
Phosphorus	1.00
Sulphur	0.09
Carbon	3.50
Manganese	0.50

and we substitute a mixture containing 2.50 per cent. of silicon, the other elements remaining the same, what do we know will be the result? In the first place we know obviously that one per cent. of the material which cost pig price will be wasted; we know, also, that one part of silicon requires about four parts of iron to slag it off; we therefore have a total loss of five per cent. of iron. This means a waste of about a ton of iron per week per furnace, which must be valued at puddled bar price. The matter does not however, end here, we now know enough of the chemistry of dephosphorizing to say that the complete removal of the silicon is effected, hence

if the puddler does not work at his heat and get this silicon into the condition of slag, before balling-up, it follows that the bar will be crystalline and break short—it will contain too much phosphorous.

This prior removal of silicon before that of phosphorous is well shown in the diagrams before you, they have been worked out from very numerous analyses of samples taken at various stages of the two processes named. I am indebted to my friend Mr. F. Harbord for the loan of that one showing the Basic-Siemens actions. I hope they show in as clear a manner as is possible the point I wish to indicate. I am aware how difficult it is for one unaccustomed to chemical language and figures to fully appreciate the significance of facts stated in chemical language alone, and so I have brought before you some pictures which show the actual progress of the removal of the various constituents.

You will see from them that the waste of iron stated above becomes a necessity unless an inferior bar can be tolerated. Thus in the diagram of the puddling process, you will see that at the expiration of half the time required for the process 98 per cent. of silicon is removed, while only 60 per cent. of phosphorous has gone. So it follows that if we started with the standard charge named, we should at this particular point,

$$\begin{aligned} & \text{have a metal containing } \frac{1.50 \times 98}{150} = 1.47 \text{ and} \\ & 1.50 - 1.47 = 0.03 \text{ silicon, but } \frac{1.00 \times 60}{100} = \\ & 0.60, \text{ and } 1.30 - 0.60 = 0.40 \text{ per cent. of phosphorus.} \end{aligned}$$

I may here state that such a result would give a splendid bar when the operation was finished, inasmuch as much finished iron contains this percentage of phosphorus, and indicating, therefore, that a much more impure charge has been used than that which is under our notice.

If we now take the case of our inferior charge containing 2.50 of silicon it will be clear that, under the same conditions as regards heat, fettling, etc., the metal at the same stage of the process will contain a very considerable percentage of silicon, probably, I should say, half a per cent., so that we may be sure it will also contain a very considerable percentage of phosphorus. We therefore are conscious of both waste and bad quality of product.

From these considerations you will see how the matter works out in actual practice, and how great the tendency is to steer a middle course, avoiding on the one hand a waste of metal, and on the other a highly phosphoric or hard iron. With a pig ill fitted for the best economy it is not to be expected that any assistance can come from the puddler himself, it being against his own interest. He is bound to make a compromise, and by increasing his yield he must keep the ball impure.

Leaving now the subject of silicon, we come more immediately to the element phosphorus. What do we learn about this in addition to what has preceded. Supposing in our normal charge we have 2.00 per cent. of phosphorus instead of our 1.00 per cent., what is the result? We gather from the examination of practical results in puddling and the basic process, that at least five parts of iron are required to absorb one part of phosphorus, so that we had a loss of some six per cent. of metal, which must be also valued at at least puddled bar, inasmuch as the same, in fact more, work and material is required for its removal, as if it had been absent, so that this element of eliminated is still more wasteful than silicon.

Sulphur does not call for extended remarks, because, although puddlers handle the name pretty glibly, they almost invariably have the wrong bull by the horns, inasmuch as sulphur is not often present in injurious quantity when the pig is a fairly grey forge, and although a high percentage of course occasions waste, I am afraid I have already dwelt too long on other matters to allow of our discussing a much less-important element.

The relations of copper and sulphur, however, are of interest in conjunction with the use of purple ore in the manufacture of iron. I am aware that there is a considerable prejudice against the use of this material. I have, however, been associated with its extensive use, both as an ore and as a fettling, and my experience is that the copper and sulphur which it contains in considerable quantity, are injurious only when they appear together in the pig or finished iron. I have seen large quantities of excellent finished iron made from a pig containing a quarter per cent. of copper, as soon, however, as any attempt was made to use commoner or sulphury pig in admixture with the coppery pig, the results were disastrous. I have found also that if there is a tendency to red-shortness in the bar, it may be removed by mixing the purple ore with some five per cent. of very fine lime, no injurious effect need be anticipated from the lime, if fine enough, and it will absorb the sulphur. This latter may certainly be set free by the silicon of the pig, but it does not enter the iron, and probably passes up the stack.

Carbon, inasmuch as it does not waste metal, but, as I have said, increases the yield, calls for no special remark. I may, however, repeat that the more the pig contains the less sulphur and generally the less manganese is present.

MANGANESE.—I must claim much partially for this element. I believe it is the key to much economy in puddling. I think there is *prima facie* evidence that it is as important in the puddling furnace as it is in a Bessemer converter, notwithstanding the fact that the finest finished iron will sometime contain only traces of it. It will, however, be found that all the best irons, without exception, are made from pig containing considerable quantities of manganese, and, indeed, in the old days, when all-mine pig—which meant manganiferous pig—was the rule, bad iron was the exception. "Iron was iron" in those cherished days; but with respect to the pig used, it would have been difficult for an ordinary puddler to make a bad bar from it. There are several reasons for this: In consequence of a manganiferous pig containing less sulphur, less work would be thrown on the fettling. The phosphorus therefore, from this cause alone, would be more completely removed. Manganese, again, makes a thin fluid slag, the ball is therefore more thoroughly washed. Again, the oxidation of the impurities of the charge may be pushed much farther than when a pig is free from manganese. This point I well seen in the basic process. In the absence of manganese in the pig the bath of metal is unduly burnt or oxidized, and the resulting steel is redshot. Such redshortness is always avoided by taking care to have plenty of this element in the pig, indeed I have myself made several blows of excellent steel by using such a pig without any of the usual additions of ferro-manganese, and I have made many hundreds of tons of steel of equally high quality in which the additions of ferro was so small that the putting of it in at all might be regarded more as a matter of form than one of actual utility.

This matter also works out practically in puddling, and in addition to what I have said abo

all-mine pig, the beneficial effect of manganese has long been recognized in Germany, and there is no doubt that its presence admits of a much more perfect removal of phosphorus. An explanation in addition to that respecting the increased fluidity of the slag may be found in the fact of the strong affinity of manganese and silicon for one another, and we have seen that it is just this silicon which is so desirable to remove.

One more instance of the probable effect of manganese may be noticed. It has been found possible to puddle hematite iron with fettling obtained from ordinary puddling, but when the fettling was itself obtained from hematite pig, the iron produced was redshort. I am inclined to think that the reason of this is that the manganese in the fettling from the phosphoric pig is possibly reduced along with some iron, by the carbon of the hematite pig. The metallic manganese then entered the puddled ball and reduced the liability of it being subsequently burnt. I give this explanation without having any evidence to support it from the facts themselves, but there is no question of the results.

Although alloys of manganese and iron are known, their formation in the puddling furnace is impossible, and there being only the silicon to alloy with the manganese, it follows that beyond the actual loss in weight due to the percentage of manganese, there is no loss in the iron due to its presence.

In this beneficial action of manganese we have the explanation of that observation that the highest class of pigs frequently yield poorer than a medium class—we get a purer iron; it will therefore weigh less. The amount of slag, again, would frequently be small; the heat would, therefore be dry, and some iron would be carried away mechanically.

The economical way of dealing with this dry condition of the heat, which, however, is not I think a frequently occurring difficulty, will be obvious from what has been said about silicon, and it is found advantageous to scatter a few handfuls of sand on the iron just before balling up. The effect of course being to make a more fusible cinder, which will clear the iron without any appreciably bad effect. Again, the use of cinder pig in the subsequent charge will economically bring down any gathering bottom. It will make a more natural cinder. These matters are, however, well known, and I fear appearing presumptuous in alluding to them. The reverse action, *i.e.*, of remedying a scouring cinder and so increasing the life of the furnace, is not so often practised. Scrap is generally used for the purpose, but the desired result may much more economically be obtained by the use of a sufficient quantity of finely-powdered lime, if it be inconvenient to change the mixtures. It is well to drop the damper when this is put in, to prevent the lime being carried on to the neck and roof of the furnace, and so slagging the brickwork. No bad influence will follow if the lime be fine enough. It will absorb the silicon of the iron, and therefore prevent the combination of the two better. It will hence be more economical to use lime than increase the fettling or scrap.

The time remaining at my disposal will not allow me to more than briefly allude to a few remaining points in economical puddling.

From what I have said about the mutual action of silicon and phosphorus in the puddling furnace, you will see the very great advantage of having such a peculiarly constituted metal as refined iron, and it may be useful to show in a tabulated form what the process of removal of the impurities in the refinery is. I give the results taken from my note-book of successive stages in this refinery process, so that you may

see the very considerable changes which have been effected.

The phosphorus in the puddled bar would be extremely low when such a metal was judiciously used with ordinary pig, hence the high excellence of the bars so obtained.

The following are the figures:—

	Per Cent.			
	Carbon.	Silicon.	Sulphur.	Phos.
Rhymney Forge Pig...	3.52	1.86	0.05	1.72
After melting....	3.42	0.62	0.05	1.65
8 minutes after melting.	3.36	0.52	0.05	1.50
12 " " "	3.32	0.38	0.04	1.46
16 " " "	3.30	0.32	0.04	0.85
22 " " "	3.20	0.23	0.04	0.85
Refined metal.....	3.15	0.20	0.04	0.80

Unfortunately the cost of producing these results is very great, and it seems to be found cheaper to use a more impure pig and do the refining in the puddling furnace itself where, as we have seen, it is done at the expense of the fettling. Now, we know that silicon at least can be removed without any such expense of oxide of iron. The first stage of the acid Bessemer process consists in the removal of silicon, so that by Bessemerising molten pig iron we obtain the desired result.

I have had the pleasure of seeing this done with forge pig in Belgium, where a refinery was attached to the blast furnace and the molten metal run into it. The effect being that some 50 per cent. of silicon and 25 per cent. of phosphorus was removed. I am unacquainted with the reasons which have prevented the more general adoption of this practice. It seems to me to possess very great advantages, and there are works at which it is extremely difficult to obtain silicious pig when using a cinder pig burden.

THE DEVELOPMENT OF MINES.

By C. M. DOBSON, M.E.

For some years the mining resources of Canada have been worked and partially developed by a few enterprising capitalists who have, either from a practical knowledge of the mineral wealth of the country, or from theories of geologists, who in pursuit of their calling have made such discoveries, entered into such speculations that in any other country than Canada would have brought the whole of the capitalists, or their agents, from London to examine and interest themselves in such properties. However, owing to an unexplained laxity on the part of the owners of these properties, the mining interests, and almost inexhaustible mineral wealth, has not been developed in a way calculated to inspire the confidence of capitalists who are comparatively unacquainted with the country and the mineral formations. It is the opinion of several mining authorities that would the promoters of public companies and mines in Canada take more of their speculations into the English market, where Canadian mining stock would acquire a ready sale, sufficient capital could be raised to efficiently develop a property. Whereas at present these great interests are almost confined to Canadian cities and Canadian capital, the result is that a mine is floated with an inadequate capital, development commences, and before any tangible result is obtained the small capital is exhausted and at the vital moment when a result is within the grasp of the speculators they "shut down" and the work that has cost so

much is left to fill up with water and the plant to indicate where another "bubble had burst." The writer could name scores of properties that have gone the same way owing to the improvident and thoughtless way of commencing operations.

Take these valuable concessions to the place where the money is, and where, if it can be proved, as it can be, that there is a chance of realizing a return, they will give all the money that is necessary for the efficient development of a legitimate speculation,

CORRECTION.

In our last issue, through misadventure, it was stated that the Hartford and Capel mines, together with all moveables, had been sold by the Eastern Townships Bank to Messrs. E. H. Nicholson & Co., of New York. The purchasers were Messrs. E. H. Nicholls & Co., and the property belonged not to the Eastern Townships Bank but to Wm. Farwell, Esq., late manager of the bank. The price realised was \$50,000. In another place will be found a list and description of other properties now for sale owned by this gentleman.

Personal.

Mr. C. M. Willmott, of the Geological and Natural History Survey of Canada, has returned from England. He was in charge of the Mineral Court at the recent Indian and Colonial Exhibition.

Mr. C. M. Dobson, C.E., M.E., one of the engineers on the River Niger (West Africa) Survey, 1885, and more recently connected with the Brantford Telegraph, is now resident in Ottawa.

Our Gold Mines.

(From B. C. Colonist.)

QUARTZ MINING.

Now that railway construction within the province has been completed for the present—though it is hoped that many of the numerous projected lines will shortly be commenced—there is time to look after some of the important industries, and to a certain extent this has been done during the past summer. Among what will in the near future prove to be the most important factor in the prosperity of the province is quartz mining, and to this branch during the past year has been paid particular attention. The richness of the ore and the extensive character of the deposits have long been known, but the fiasco upon the first introduction of quartz machinery and the great work later of building the Canadian Pacific through the province served to keep the quartz interests in a dormant condition. However, they are on the eve of a revival and the coming year will see large developments.

Probably the greatest effort being made in the province to work a mine is the work now proceeding on the Foster Milling & Mining Co.'s property, with works at what is known as the Big Slide, some fifteen miles below Clinton. This company have quartz mill and chlorination works in position, have unlimited water power, and, so far as known, a continuous body of rich paying sulphuretic ore. Assays and mill tests go to prove that it will pay richly for its treatment, and a result will soon be known.

The famous ledges of Cariboo in the immediate vicinity of Barkerville are again being developed. The British Columbia Milling & Mining Co., with works at Lowhee creek, have begun to develop their extensive property. This company have already complete buildings, magnificent quartz machinery and engines. Their mine has been prospected sufficiently to show a body of ore eighteen to twenty-five feet in width, and mill tests and assays have proved that it will pay for its being treated. Considerable work is now being done in sinking a working shaft, drifting and cross-cutting.

The Island Mountain Mine, owned principally by Mr. P. Dunlevy, of Soda creek, is also being developed. During the present winter tramways to the mine, tunnelling and drifting and the removal of the mill and other machinery to the site selected, fronting on Jack of Clubs lake, is being carried on, and it is expected that during the coming summer matters will be in a sufficiently advanced shape to begin the work of crushing and reducing the ore.

On the old Steadman ledge, crossing William's creek at Richfield, a small sum will be spent in placing the tunnel in good shape and extending it.

Besides these works, various other ledges of promising character will be more or less developed.

At Hixon creek the already largely prospected mine will be further worked, the mill removed to a more favorable location on the opposite side of the creek and everything got in position for extracting gold.

Along the line of the Canadian Pacific, from Kamloops lake to the boundary line, a great deal of work has been accomplished during the past year in prospecting ledges and placing in machinery to crush or smelt the same. In the Selkirks and Rocky Mountains are wonderful deposits of galena and large deposits of gold bearing rock. North and south of the line of railway, in the Big Bend, along the shores of the Columbia and Kootenay rivers and lakes the capitalist and prospector have visited, and there is every promise that soon the rocky canyons and shores and hills will be compelled to yield up their precious treasures to man.

Coming nearer home, several discoveries have recently been made on Vancouver Island, within easy distance of Victoria, of ledges of gold bearing rock, but none of these have been thoroughly tested, though assays and mill tests have proved that there is gold in quantity sufficient to entitle their being milled if the ledges prove to be continuous in extent.

There has been considerable enquiry from many portions of the Dominion, United States and England as to the minerals of this Province, and many assurances have been given by men of capital that they will invest money in the development of the quartz mining industry. Taken altogether the work accomplished toward creating an activity in quartz mining in the past year must be regarded as satisfactory, and it is not too much to hope that 1887 will witness a progress and prosperity in this individual industry that will be of the greatest benefit.

PLACER MINING.

The past year has not been productive of results as good as in the early part there was reason to believe it would bring. In Cariboo district, owing to the very dry season, work had to be shut down on various of the hydraulic claims, there not being sufficient water to work them. The output for the year is somewhere less than that of any other during its history as a mining field, solely on account of a lack of

water. However, a few new discoveries were made, and it is thought that the coming year will again place the gravel mining industry in a prosperous condition.

Granite creek, in the Similkameen district from which such good results were anticipated has not come up to expectations. Though a few claims on the creek have paid well, a great number of miners who went in have returned without securing any pay, and the several other creeks in the neighborhood have also failed to produce gold in paying quantities.

In the Big Bend country a considerable number of men have been at work during the entire year. On Carne's creek moderately good returns were secured. On McCulloch and French creeks, where deep mining and hydraulic mining are being carried on, some rich gold has been secured, but work has not advanced sufficiently to permit of a correct estimate being formed as to the continuous richness of the district. However, those who are engaged in mining work on the various creeks have every faith that Big Bend next year will show good results. The cost of packing in supplies has seriously operated against the success of the camp.

Cassiar has somewhat improved in the past year, better returns having been secured from the old ground and a new field having been discovered which gave large returns for the limited amount of work done. There will likely be an increase in the number of miners who will go into that district this coming season.

Lorne creek has proved a failure, little return being secured, for the large amount of work done. For the greatest part of the year high water interfered with mining and those engaged have either lost money or scarcely made wages.

One of the best fields during the past year has been that of the Stewart river, a large tributary of the Yukon. This is in the northernmost part of the British possessions, and all those who mined there during the past season have made money—some \$600, others \$6,000. There will undoubtedly be a large rush for this field and preparations are now being made to take in adventurous spirits in the early spring before snow and ice disappear from the rivers and lakes.

Kootenay district will return about the same yield as the previous year. Considerable prospecting has been carried on but no new gold bearing creeks have been discovered. Extensive preparations are being made for hydraulic next season on a large scale, notably on Findlay creek. The near presence of the railway and the probable construction of a feeder south from the C. P. R., will likely induce a large development of the latent resources of the district during the coming year.

In many other portions of the Province, especially in Yale and Lillooet districts, gold bearing creeks have been discovered and worked with moderate results being achieved. On Vancouver Island a large number of Chinese are engaged in mining. This is especially the case on Bear river in Alberni district, where it would appear that they have made a rich strike from the number who have proceeded to that point.

Taken altogether the past season's work has been moderately satisfactory, and there is every reason to believe that the year 1887 will be productive of largely increased results from placer mining. Supplies are cheapening, shorter, easier, quicker and less expensive routes to the mining fields are being provided, and many fields that previously would not pay to work on account of the high price of provisions and other necessities, will be called upon to furnish their quota to the general prosperity of the gold mining industry.

DUST IN COAL MINES.

VALUABLE PAPER READ BY MR. M. MERCER, WIGAN; BEFORE THE MANCHESTER GEOLOGICAL SOCIETY.

It may be taken for granted that all or nearly all colliery managers and mining authorities are now agreed that coal dust does, and has in the past played an important part in augmenting the intensity and disastrous effects of many of the explosions in mines; whilst a great many authorities are of the opinion that coal dust can by itself under certain favorable conditions cause an explosion similar or even more severe in character and effect, to that caused by fire-damp alone—a proof of which may be cited in the late sad calamity at the Altofts colliery. Evidence at the former is amply furnished by the explosion at Seaham, Dinas, Trimden Grange, &c. To go into the proof of the theories is unnecessary, as it is dealt with extensively in the report of the Royal Commission on Accidents in Mines, and also very fully and concisely in the valuable work on "Explosions in Coal Mines," lately added to the literature of the mining world by Messrs. W. N. and J. B. Atkinson, Her Majesty's Inspectors of Mines, and which should be read by all who are interested in so important a subject. Now, in the first place must be considered the causes responsible for the large amount of this dangerous matter in most dry mines, which will probably be accounted for severally or collectively by the following: 1. The working and getting of the coal at the face. 2. Decrepitation of the pillars and coal scattered in the roadways. 3. Leakage from tube and boxes. The remedies for these evils may be found in the following: 1st. Mode of working, in which there is not much room for improvement: the long wall system being considered much superior to pillar and stall, as it does not leave any pillars to crush and decrepitate, which when being removed produce a large amount of fine dust. 2nd. In the mode of haulage and form of tubs there is probably the most room for improvement, as the systems in use in many collieries are very prolific in the generation of fine dust. The worst of which seems (a) the use of boxes made of green timber which, after a few weeks use in a dry mine, shrink and leave a wide space between the boards, through which the dust is continually falling; (b) the form of boxes in use in some of the South Wales collieries, which have the sides constructed of a lattice work of iron. The remedy for these are—(a). The use of dried and well seasoned timber in the construction of wooden boxes, which should in all cases have grooved or covered joints. (b) The use of sheet iron boxes, fitted with wooden or indiarubber buffers to reduce the shock caused by the boxes jamming against each other. (c) The systems of haulage at high speed are probably the greatest producers of dust, and wherever possible should be superseded by some form of haulage that can be carried out at speeds of two to three miles an hour, such as endless rope or chain with a double line of rails. After having as far as possible remedied the causes of dust generation (which remedies can be only partially successful), there must next be considered the means available for dealing with dust in mines. The first consideration must be its removal from the workings; and the next how to render its properties of danger harmless. With reference to the former: The removal of the dust entirely is not practicable for to be done properly would require an army of scavengers being kept constantly at work, and even then the finest and most dangerous particle would still remain; again, unless water is copious

ly applied during its removal large clouds of fine dust will be constantly passing with the currents of air to the danger of the mine, and will be again deposited on the roof, sides, and floor of the roadways. With reference to the latter consideration, viz., how to render the dust harmless, there have been several methods proposed. 1. It has been proposed to raise the temperature of the intake air to the natural heat of the mine; it being claimed that all air entering the mine at a low temperature is gradually raised, in doing which most of the moisture is evaporated from the dust. This antidote (which would only prove partially effective) is most impracticable, as it would be very costly to artificially heat the air some 20 to 40 degrees, and as deep mines are at present much too hot for comfortable working, if the temperature of the mine be thus increased, as it would by the suggested method it would probably necessitate the paying of extra wages in the getting of the coal. The heated air would probably affect the roof and sides of the mine, and also decrease the quantity and efficiency of the ventilation, so making the "cure worse than the disease." 2. Strewing the work with common salt or brine has been proposed, and is used to some extent to keep the dust in a moist condition. It gives good results if used on the following basis:—One pound of salt per square yard of area, applied once a week for the first month, and once a month afterwards. Its use has the following disadvantages:—Salt is expensive, costing about 9s. per ton (though if used extensively it could probably be obtained at a cheaper rate). The cost of labour in spreading the salt will be heavy, and additional matter will have to be removed, this again adding to the already heavy cost of working mines. 3. The turning of exhaust steam into the air courses has been proposed, but anyone who has had to do with steam engines in a mine, knows the havoc it works with a roof composed of shale, therefore there is little probability of this method being used to any extent. 4. The best and most practical method is the watering of the roads by (a) water carts, or (b) the laying of pipes in the haulage roads and main air courses; both of these methods have their advantages and disadvantages. These require very careful consideration, as it will be in these directions that the solution of the problem must be expected. (a) The watering of main intakes and returns by water carts, of which there were several varieties, viz., ordinary water carts with holes in the bottom, carts constructed on similar lines to those used in street watering, with a pipe at the back to diffuse the water by its flowing through small apertures in the pipe. A very ingenious cart was constructed by Messrs. Smethurst for use in their mines at the Gatswood Hall Colliery. It consisted of an ordinary water barrel mounted on tram wheels; at one end was fixed a hollow circular rose perforated with small holes around its circumference, and connected by gearing to a toothed wheel on the axle of the tram wheels. The water was delivered into the centre of the rose or disc, which revolving very rapidly when the tub was in motion, scattered the water by centrifugal force against the roof, sides and floor of the roadways. The disadvantages of this system are—1st. The cost of conveying the cart about the mine, which will also interfere with the ordinary coal traffic. 2nd. The cost of keeping a road constantly laid in the return air courses. 3rd. The water falling in one place only when the carts are stationary, will have an injurious effect on the floor in that particular spot. This, however, can be remedied by so arranging the cart that it shall automatically close the outlet when the cart is not in motion. The

second system consists of the laying of water pipes along the sides of the main road and air courses; this appears the most feasible, if properly arranged to conduct water from the surface, or any convenient level in the shaft. The pipes being provided at suitable intervals with collections of small holes or apertures to diffuse the water in the form of five sprays into the road. The distance apart of these sprays would have to be determined by practice, and should hardly need to be less than 10 to 20 yards. This system if properly carried out with a good head of water, possesses the following advantages:—1. Is a very sufficient method, as the water can be turned on when the mine is not working so as to cause no inconvenience to the men employed. 2. Does not require the keeping of a permanent road in the return airways. 3. After the first cost of pipes and fixing would not require any heavy expense to keep in working order. 4. Would prove of great service in case of fire in the mine. 5. Can be connected with the working face and drawing roads by flexible tubing. 6. Will not injure the health of the men as the atmosphere will not be saturated with moisture in suspension during the time the men are at work. 7. Can be so regulated that only the proper amount of water shall fall on the roadways to damp the dust, as with a soft flood the water in excess will cause the warrant to heave. Its disadvantages are:—1. First cost of pipes and fixing, which will be heavy. 2. Danger of the small apertures becoming clogged by dust and dirt. 3. Danger of the pipes being broken by falls of roof and sides, and the lifting of the floor. These can be somewhat guarded against by having the pipes slung from the timbers, and providing expansion joints and stop-cocks, so that the water can be turned off at any particular point or branch during repairs. 4. The necessity of having clean water free from all matter in suspension and accompanied by a good pressure, this again being of itself a counter disadvantage as it necessitates the use of stronger pipes. 5. The necessity of having suitable settling tanks and grids, to prevent any solid matter entering the pipes. In conclusion there are several points to be considered. 1st. Is there any necessity to damp the dust in any other than the main haulage roads and the return airways near to the bottom of the upcast shaft. Messrs. Atkinson have clearly demonstrated that in the explosions of which they treat in the book alluded to, "that the blast did not in any of the instances quoted travel to any extent in the returns." They further draw attention to the established fact "that in all explosions the blast travels against the air towards the downcast shaft," as a confirmation of their theory that "the dust in the return being chiefly composed of shale and metal does not transmit the blast." At the late explosion at the Altofts colliery the same phenomena was observed, and this was also the case at Mardy, &c. 2nd. What will be the effect of damping the floor in mines that are subject to creep? Will the frequent slight waterings of the dust be sufficient to keep it moist without allowing the water to affect the warrant? 3rd. Will the spray at specified distances be effectual in rendering the dust on the sides and timbers harmless? 4th. The advisability of dissolving salt in the water so utilised, and will it be likely to crystallise and stop up the apertures? 5. The advisability of hanging a sheet of brattice cloth, saturated with water, over and in front of all shots fired in the coal or metal, as a preventive to the flame during the dust. 6th. The advisability of reducing the velocity of the air in haulage roads by enlarging their areas, or provided additional roads for the intake air. 7th.

The advisability of adopting the remedy, suggested by Messrs. Atkinson, of separating each district by means of lengths of arching, to be kept quite free from dust by brushing and watering, and to confine an explosion to the one district.

Beauce Gold Mines.

AN INTERESTING DISCOVERY MADE ON THE ST. ONGE PROPERTY—ENCOURAGING INDICATIONS.

The St. Onge Gold Mining Co. have established the fact that there is an ancient river channel running through the company's property at a depth of 165 feet from the surface, from which channel a considerable quantity of fine and coarse gold has been washed. News has just been received by the president of the company that the ground is getting richer as the head of the rapid (on which the shaft was sunk) is reached. In January ten feet of drifting produced nine ounces of gold. One nugget was worth \$23.27, another \$13, and so on. The owners deserve every success for the plucky way in which they have stuck to the development of their property. We hope to be able to give a full report of the workings in our next issue. Already a good deal of excitement has been created by the recent find.

WASTE MICA.

SOME USES TO WHICH IT CAN BE APPLIED.

The best employment of the immense quantities of scraps and fragments of waste mica which suggests itself as worthy of a wider field than it now possesses is the substitution of mica for glass in spectacles worn by workmen, especially stone and metal workers, to protect their eyes from chips and splinters. As already made in Germany, these mica glasses are concaved in the shape of watch glasses, and are about one twenty-fifth of an inch in thickness. The advantages gained by this utilization are greater than would at first be imagined. Mica spectacles cannot be broken. Pounding with a sledge hammer merely flattens them, nor does molten metal poured on the mica affect it. The shower of pointed iron particles which issues from lathes merely rebounds from the elastic mica glasses. Another use for mica is its application, when previously colored or metalized, to ornamental purposes. From its unalterable nature, the material preserves gilding, silvering or coloring from deterioration; and from its diaphaneity, the articles so treated will preserve all their brilliancy. Finely ground mica, or colored gelatin, also shows handsome effects, and when mixed with a solution of gum arabic, it makes a good silver ink. The gelatin combination is used for inlaying buttons. Another beautiful application of mica is in the production of bronze-like colors, which bear the names brocades, crystal colors and mica bronzes. Among the advantages of these are that they are indifferent to sulphurous exhalations, are very light in weight, and in some colors are even more brilliant than the metal bronzes. When small particles of mica silver are spread over articles coated with asphalt varnish, the result is a good imitation of granite. The crystal colors are also suitable for calico printing; and fabrics to which they are applied surpass in brilliancy the heavy bronze and glass dust fancy fabrics of Lyons. Such colors have been used to decorate porcelain and glassware, the articles undergoing a second heating up to the fusing point of their

glazing. By suitable dyes, the material is easily colored to a variety of hues.

Mica has been used on board war vessels, in localities where glass would be broken by the concussion due to the firing of heavy guns. It is also employed for roofing purposes, and in several patented processes forms a water and fireproof covering for strata of rubber, tar, canvas, felt, and similar materials.

Mechanical Ventilation of Mines.

At the present time more than ordinary attention is being directed to the best means of ventilating mines, more particularly those where a large quantity of gas is constantly produced. The atmospheric air sent through a colliery undergoes in its passage certain modifications which renders it unable to keep the workings clear of gas. The respiration of men and animals gives birth to extremely deleterious gases. Sulphides become sulphates, carbonates turn into peroxides, whilst vegetable and other matter undergoes fermentation in which the oxygen disappears and gives way to carbonic acid, carburetted hydrogen, nitrogen and ammonia. For the safe working of our mines it is, therefore, essential that there should be a large and constant supply of fresh air sent from the surface so as to permeate every part of the workings. To effect this, various systems have been in operation, including the furnace, fans, steam jets, screws, etc. The furnace has long been the means of ventilating most of the collieries in every part of the kingdom. The amount of air produced by a well constructed furnace varies from 4,000 to 8,000 or 9,000 cubic feet per minute for each foot in breadth of the bars. Still the temperature of furnaces is very variable, and to some extent also the ventilation, while there is considerable danger in the return air containing the gas being carried over the furnace instead of through a dumb drift into the shaft. The furnace is also a source of danger from other causes. For a few years ago the stack for feeding the furnaces ignited at a large colliery in England, then set fire to the coal, and led to a loss to the proprietors of more than \$300,000, and to the pulling down of a powerful fan.

But mechanical ventilation, it may be said, is by no means a new system, although of late it has made very great progress, for we find the Duck machine was in use at the commencement of the present century in Cornwall, Eng. Mr. Strauvé, of Swansea, made some important improvements with respect to aërometeos. By covering them so as to make them double acting, and placing the valves at the side, he succeeded in producing a machine far superior to any that had preceded it. Of late years however the superiority of the fan has been clearly demonstrated by Mr. Morrison, of Newcastle, the agent of the Guibal, which deservedly takes the highest rank. The Schiele fan, an economical one, taking up comparatively little room, and not requiring either expensive machinery or masonry, has made marked progress of recent years.

Ventilation by means of the steam-jet was revived some years ago, but this system failed.

A new company, under the name of the "Templeton and Blanche River Mining Company," has been formed with a view to carrying on the phosphate industry. The capital stock is \$33,000, divided into shares of \$100 each. Messrs. H. Beaugrand, W. Cassils, L. Sutherland, S. C. Stevenson, P. S. Ross, H. Graham, H. S. Reddy, D. Anderson, J. Beattie, A. Rudolph and A. M. Perkins, of Montreal, are prominent leaders in the enterprise.

PHOSPHATE.

LATEST QUOTATIONS.

There is already some enquiry, chiefly from the Continent, for Canadian Phosphates for delivery during 1887, but as buyers are indisposed to advance upon last season's prices no business has resulted. Ground Canadian testing 60 to 68 per cent. is now likely to become an article of annual importation, and Sellers are disposed to contract for further supplies during the coming season. South Carolina Phosphates. —The possible infliction by the State Legislature of a second dollar export duty upon River Phosphates has caused a slight stiffening in prices, and Raisers are more than ever unwilling to sell at late rates, indeed, contracts have already passed at more money. Some of the manufacturers of Ground Belgian have been obliged to succumb to the unremunerative prices obtainable, and sellers are demanding an advance for their Phosphate, which has become almost a necessity to the trade. The new French Phosphate is now being delivered, and realizing the promises of its sellers. The chemist's report upon two actual shipments made last week show 73.74, 73.85 per cent. Phosphate of Lime, Alumina 0.11, 0.23 per cent, and Oxide of Iron 0.94, 1.09 per cent., respectively. Cambridge and Bedford Coprolites are unchanged, and quoted at 41s. f.o.r., or ground at 48s. in buyer's bags, or 50s. in lent bags, f.o.r., the latter at 26s., f.o.r., or 31s. 6d., f.o.b., Thames.

EXPORTS, 1886.

The report of the Montreal Board of Trade shows that there was exported from that port in 1886, 18,968 tons of phosphate, against 23,849 in 1885, and 20,747 in 1884.

PHOSPHATE IN FRANCE—A NEW DISCOVERY.

The deposit of phosphate of lime discovered about three months ago near Beauval, in the department of the Somme, has proved to be remarkably rich. This deposit had really been located some twenty years ago, but so little attention was then given to its value that, until very lately, these phosphates were sold in the neighborhood as common building sand. Recent complaints having been made about the quality of the sand, one of the owners of the bed took it into his head to have the material analyzed, and then discovered that he owned a perfect bonanza. The analysis of these phosphates shows them to contain 66.43 per cent. phosphate of lime, 5.60 per cent. carbonate of lime, 3.26 per cent. fluoride of lime, and 1.43 per cent. sulphate of lime. The deposit of sand seems to cover the whole of the clay beds of the Beauval district, and varies in thickness from a few inches to 30 and 36 feet. It also fills all the cavities on the surface of the clay. Under the microscope, it shows itself full of shells and infusorial remains. It weighs about 66 pounds to the cubic foot.

A Monster Nugget.

There is at present in Wells, Fargo & Co.'s bank a bit of auriferous rock that any individual might be glad to possess. The nugget is one of the finest unearthed in California, both in size and richness. It is irregular in shape and about the size of an ordinary Derby hat. That there is very little rock and a great deal of gold in it may be determined by its weight, which is thirty-five pounds troy. Quartz of this sort is usually valued at \$200 per pound, and, allowing the large margin of \$1,000 for rock, the nugget would be worth \$6,000. The exposed rock and great gobs of gold that hang out of its sides so as to

nearly hide all other composition and make it appear almost as melted metal, are not jagged or rough, but on the contrary, are smooth and polished in a manner that only water is capable of. The proprietors of the nugget are Messrs. Hayes and Steelman, of Sierra City, and they have left it on exhibition for a few days. At the bank it attracts much attention, but the employees could furnish no information concerning it beyond that it came from Sierra county, near Sierra.

The Continental Iron Trade.

The extreme depression which characterises the Westphalian coal trade can hardly be said to extend to the iron trade in the same district. It is possible that there may be a good deal of exaggeration and undue hopefulness in the estimate formed by those concerned in this industry of their immediate future. But it is quite certain that there is increased activity in the trade, and a growing demand for home ores. Prices also have risen, although not to a very material extent. The advance, however, has been sufficient to induce a number of mining proprietors to reopen mines which had long been standing idle. Blast furnaces, too, are very busy, and the demand is quite equal to the production. In these circumstances, it is not surprising to hear that makers are but little inclined to enter into any contracts extending further than the end of March. While on the subject of the iron trade we may say that prices in Belgium also continue firm. But in France the improvement is exceedingly slow. It is remarkable, indeed, how completely the manufacturers and producers of the French Republic seem to be losing their hold on the world's markets.

The *Colonist* reports that two mines have been discovered right along the C. P. R. line through the Selkirks, but the want of machinery and capital has yet prevented their richness being fully tested. They are both along the Illecille river. One mine, situated at Albert Canon, is only 400 yards from the track. It is said to have a vein of gold bearing quartz 20 feet wide. For the past year a few men have been employed in taking out ore, which has to be shipped to outside points to be assayed, as the necessary machinery has not yet been placed in the mine. There is another mine about ten miles beyond the summit of the Selkirks; it is situated about a mile from the track and fourteen ponies are constantly employed in bringing the ore down the steep slopes of the mountain for transmission. Machinery is to be placed in this mine also next summer.

The introduction of ambulance lectures by professional medical men, by which workmen and others are taught how to act in cases of emergency, has already been the means of saving many lives and it is not too much to say that the foreman and leading workmen of all engineering establishments should be encouraged to attend such lectures free of cost to themselves, even, if necessary, in the time of their employers, as their services, should occasion arise, would be freely given, to the great advantage of the unfortunate sufferer. Even keeping a supply of lint, linen rag and sticking plaster upon the premises is not to be lightly prized, as many a poor fellow who has been struck by a hammer or cut by a flying chip or iron can testify, and such slight mishaps are common enough.

At the last meeting of the directors of the Rabbit Mountain mine the sum of \$20,000 was set apart for the development of the property.

SCIENCE.

OTTAWA LOCAL GEOLOGICAL WORK.

The series of "Monday afternoon lectures" under the auspices of the Ottawa Field Naturalists' Club was inaugurated in January last in the Museum Room of the Ottawa Literary and Scientific Society by Mr. Henry M. Ami, of the Geological Survey Staff. Whilst these lectures are meant chiefly to give these members who desire it an insight into the elementary principles of the various branches of natural science which comes within the pale of the club, there is often added information which bears upon the resources that these several studies seek to investigate and develop, whether in mineralogy, geology, zoology, ornithology, botany or entomology. Mr. Ami had been requested to address the members, and in the course of his remarks which were all of an eminently practical nature to those who desired an insight into that subject as well as to those who sought further information, he briefly sketched the attractions and points of interest which geology affords, presented its aims, and in a lucid manner explained the few leading terms with which it is necessary to become familiar in pursuing such a science, viz.: faults, dislocations, flexures, anticlinal, synclinal, monoclinical, horizontal, inclined, conformity, unconformity and such like in reference to strata and their structure. Having described the various epochs which have been characterized by the introduction or presence of certain types of animal life in the physical history and evolution of the earth up to the present time, the economic minerals to man which were stored up in these several epochs, such as *coal, petroleum, lead, copper, silver, gold, &c., &c.*, the lecturer then applied the principles and elements of the science to the particular district which it is the province of the club to examine—Ottawa and its vicinity. Taking a line of section from King's Mountain, Chelsea, and running it through Parliament Hill at Ottawa a diagram shewing the various geologic formations met in this section was then discussed. The Laurentian system was here represented by two formations, which Sir Wm. Logan referred to as the lower and middle Laurentian formations, characterized by gneiss and gneissoid, as well as nonblendic rocks and crystalline limestones, respectively overlying the former. The next formations met belonged to the Palædgon period, or series, and these rested unconformably upon the upturned edges of the Laurentian rocks. There had been a lapse of time between the deposition of the Laurentian and the deposition of the Potsdam formation, which latter was characterized at its base by a series of coarse conglomerates containing huge rounded pebbles of quartz and other rocks of Laurentian age imbedded in a sandy or arenaceous mixture, as one might find along a modern sea shore or beach. The next formations met were the calciferous, the chazy, the Black river, the Newton, and lastly the Utica formation—all Palædgoic rocks—and in a regular unbroken sequence perfectly conformable one on the other and forming a series of sedimentary strata of considerable thickness (to be ascertained yet) and containing parts of petrified organic remains or fossils, which enable the precise horizon or age of the strata to be ascertained. The newer or Post Tertiary deposits were then casually referred to, as the lecturer purposes presenting this subject before the club at one of its soirees next month,

the subject being, "The great Ice age and subsequent formations at Ottawa."

The work done up to date in geology about Ottawa was then referred to and the workers late and present noticed. There had been considerable work accomplished both in mineralogy and palæontology. There was a great deal yet to be done in all branches of geologic investigation, and a small army of workers would not exhaust the field for a long time.

Ottawa was a particularly favorable spot for researches in geology and mineralogy. It was destined to hold a very conspicuous position, as the neighboring rocks teemed with valuable minerals. The *iron, apatite, epaphyite* and *barytes* of the vicinity were only touched upon by the lecturer as they alone would suffice for lecture upon lecture.

An agreeable discussion took place at the conclusion of the *causerie*, in which, besides the lectures, Mr. McLeod (engineer), Dr. Small, Messrs. Harrington, Whyte and others took part.

BOOK NOTICES.

The great advances made in recent years in the industries of the United States has raised the question in England of American competition in the iron and steel trade. It has been asked if the Americans are in a position to dispense, from time to time, in great measure with English assistance in supplying them with iron, and if the day may come when American producers will not only meet them in all the neutral markets of the world but even extinguish the furnaces of Cleveland and Cumberland, of Scotland and of Wales. About twelve years ago Mr. Isaac Lowthian Bell (now Sir Lowthian) represented the English Government at the Philadelphia Exhibition, and during that visit took the opportunity to investigate into the position and prospects of the American iron industry, and since then he has been a careful observer of its progress.

In a recent issue of the *Fortnightly Review* he contributes an able paper on the "Iron and Steel Trade," in which he deals exhaustively with this question and claims that as long as Great Britain can command raw materials at their present cost there does not appear much chance of the United States offering successful competition to it. Some idea of the value of his paper may be gleaned from the following extracts:—

"Upon a recent occasion I constructed a table which was brought down to the years of the largest iron production the world has ever known, viz., 1882 and 1883. In it an estimate was made of the actual quantity of the metal consumed in the United Kingdom and in the United States. It commenced with 1878, when our own country used more iron than any other nation. At that time the United States worked up to 70 per cent. of the weight consumed in this country. In 1883 the figures were almost exactly reversed, i.e., the consumption in the United Kingdom was just about 70 per cent. of that of the United States. The estimate was based on the quantity of pig iron used as such, and the equivalent of pig required in the production of the metal in its more advanced states of manufacture, such as steel, malleable iron, &c."

He states that in 1870 England contributed 51.6% towards the world's output of crude iron, and that our share has steadily fallen to 38.4%. Meanwhile, the United States had advanced from 14.4 per cent. to 20.2. These figures are

up to 1884, but when the returns for 1886 are available it will be found that the United States percentage of the total is much nearer 40 per cent. than 20 per cent.

He mentions that whereas the area of English coal deposits is but 7,000 or 8,000, the United States measures underlie 200,000 square miles. On the other hand he thinks that the iron ore deposits of the United States are very little, if at all, more extensive than English beds of ironstone.

In 1870 twenty-nine million tons of coal were raised in the United States; but, in 1885, one hundred and two million tons were extracted, an increase of 248 per cent. During the same period British coal output rose from one hundred and ten million tons to one hundred and fifty-nine million tons, an increase of 44 per cent. Sir Lowthian Bell lays stress on the advantage the home manufacturers possess by reason of the proximity of the ores to the fuel in Great Britain and he refers to the royalties payable there, which greatly add to their cost of production. He estimates that the royalties work out thus:—"Made from the Lias ironstone, amount to 3s.; made from ordinary clay ironstone in Scotland, 3s.; made from Blackband clay ironstone in Scotland, 4s. 10d.; made from hematite in Cumberland and Lancashire, 6s. 3d. In Germany they only come on the ton of pig iron to about 6d. In France they only come on the ton of pig iron to about 8d."

MINING NOTES

Nova Scotia.

The returns from the Oldham gold mining property for the past three months are as follows

October, - - - -	115 19 oz.
November, - - - -	61 2
December, - - - -	109 28

We are informed that the proprietor cleared \$2,165, the value of a gold brick from the mine. It weighed 113 oz. 18 dwts., and was the result of one month's work by 20 men.

The output of the Springhill mines for December, reached the unprecedented figures of 43,026 tons, which closes the year with a total of 468,000 tons, an increase of 118,000 tons over 1885. The collieries are kept busy at their utmost capacity, and give employment to between eleven and twelve hundred men and boys. The South Slope is being opened out and 200 tons of coal hoisted and shipped daily. Other preparations are being made for a further increase of business this year. Shipments of coal by water from Parrsboro, in 1886, were 40,508 tons, against 26,215 in 1885.

It may not be generally known says the *Critic*, that an American company from Pennsylvania has been boring for oil in the Memramcook Valley, Westmoreland County. They have acquired large areas of territory and within the past three or four years have sunk quite a number of wells, but without success as yet. At present they are boring in what is known as the old Ayers Mill property, about 3 miles northwest of the Memramcook Station. As they have spent large sums of money it is to be hoped that their efforts will be crowned with success. Hon. A. D. Richard, barrister of Dorchester, is solicitor of the company.

Some five or six carloads of matte from the Mineral Vale property, New Ireland, Albert County, have been forwarded for export to Swansea. The value of the matte is placed at \$100 per ton.

An endeavor is being made to engage Nova Scotian miners for work at the Bow River coal mines, N.W.T.

The West mine, Rawdon property, has been sold to Minnesota capitalists, and new machinery including a new 20-horse power engine and boiler is to be added, while steam hoisting and pumping gear will supersede the work now done by horse power. Mr. Dissoway, lately of Mooseland, Tangier district, is mentioned as the new manager.

The main shaft at the east mine, McNaughton property, is now down some 500 feet. A fire recently broke out in one of the buildings, and might have proved a serious conflagration but for the speedy action of the miners, who quickly extinguished it. Some damage, however, was done to the roof of the mill building.

Referring to the very large increase in the output and shipment of coal from the mines of Nova Scotia during the past year, the *Montreal Gazette* in an editorial very clearly points out that this is in very large measure due to the policy of protection adopted by the province. It states the case thus: "With the product of their mines shut out of the United States, and the market of the Upper provinces taken away from them by the competition of United States collieries, the home consumption of the province itself would have afforded employment to but a fraction of the number of miners now actively at work, and an immense amount of capital invested in coal properties would have been deprived of its earning power. As it is, under the protection policy, means of livelihood are afforded within the country to thousands of miners; Canadian vessels and Canadian railways, instead of United States railways, are occupied in the transportation of the product, and large sums of money that would otherwise be sent to foreign lands in payment for coal and freights are kept within the Dominion. And the benefit is not alone to the province, for the supplying of the families of the miners affords a market for the factories and work people of other parts of Canada, to the mutual advantage of each.

The value of the gold exports from this province, for the month of December, amounted to \$18,000.

Gold has been discovered in Hants County, near Ardoise Hill, and at a point about four miles from Mount Ninack. Indications said to be good.

The Egerton Gold Mining Company with a capital of \$40,000, are preparing to open up the Fifteen Mile Stream Gold mine, while it is reported that an American syndicate have purchased extensive copper and iron deposits in Cape Breton, and that the product of the Spring Hill mines for December was larger than ever before. All the different gold districts are being worked to great advantage. Salmon River, Lake Catcha, Cariboo, Moose River, Rawdon, Renfrew, Oldham, Brookfield, and Caledonia districts are yielding regular returns, and Mooselands, Gold River, Malaga Lake, Milipisgate Lake, Mill Village, Carleton and Kemptville, are being rapidly developed, and when the mills in course of construction are finished, will swell the

list of gold producers. Gold has been discovered in Annapolis County, and prospectors in all parts of the Province are preparing for a vigorous campaign as soon as the snow leaves in the spring, and many new and important discoveries will almost certainly be made during the present year.

During the month of December 30 tons of quartz were crushed at the McEwen mines, which yielded 85½ ounces.

Ontario.

PORT ARTHUR DISTRICT.

The ore at the Silver Falls mine is said to be averaging \$28.00 to the ton, with good indications.

The *Sentinel* announces that the latest assays from taken at the Palisade mine realised \$100 per ton.

The shaft at Silver Falls mine is now down about 55 feet. Two recent assays give 18½ and 28½ oz. of silver to the ton.

Work is suspended until the spring at the Silver Hill property. Major Bell is now in England endeavoring to sell the property or to secure a company to develop it.

Two hundred and eight feet have been sunk at the Rabbit Mountain mine.

Few matters so materially affect the well being and wealth of both Eastern and Western Algoma, as the present mining regulations of Ontario. Under them, if a man has money, he has only to employ a surveyor, make an affidavit that there are indications of mineral or metals on the land he wishes to grab, and by paying two dollars an acre, purchase as large a tract of land as his purse will allow, and except upon the small portion reserved for public roads, no person can trespass. This system exists throughout the district, is fast becoming a very serious check to its proper development, and should be promptly put a stop to. The Silver Islet mining company, who operate a spot of a little over an acre in extent, have 27,000 acres thus locked up, whilst there is probably about six times that amount held by speculators in grants of from two hundred acres and upwards.

Recent specimens from the Jarvis property are said to be expected to assay from \$15.00 to \$30.00 per ton. These samples have been brought to Port Arthur by Mr. A. S. McEwan.

A limited liability company, says the *Engineering and Mining Journal*, has been organized in London, with a capital stock of £100,000, shares £1 each, to acquire 240 acres in extent, freehold, consisting of two mining locations on Silver Mountain (Shuniah Weachu), in the Thunder Bay District, on Lake Superior. The vendors receive 25,000 shares and £30,000; 9,000 fully paid-up shares will be allotted to directors in lieu of remuneration for two years, and to other parties for services rendered. The mine is about twenty miles from the Canadian Pacific Railroad, and ten miles west of Port Arthur. Messrs. Frank Tobin and James Nancarrow, M.E., visited the mines in October, and upon their report, which is very unsatisfactory and indefinite one, and which affords no basis whatever for the price asked for the property, its purchase was completed. Messrs. R. J. Battle and E. C. Garlick, mining engineers, of Cleveland, also made equally unsatisfactory reports.

British Columbia.

The latest discovery of coal is reported from Tumbo Island, in the Straits of Haro. The deposits are reported large, and the quality of the coal excellent. A company has been formed to develop the deposit.

Since the year 1858, when the first great rush to the gold fields of the Fraser occurred, until the present date, fully \$50,000,000 in gold dust has been yielded from the mines, and competent authorities state as yet that they have only been scratched over—only the easier secured and rich paying deposits have been worked. Certain it is that as yet the country remains only prospected around the famous fields, and that in many sections of the gold belt nothing has been done. There are in Cariboo and other districts to-day known mining grounds that will richly repay a moderate expenditure of capital in hydraulic on improved principles. But this is not the class of mining that is now looked forward to as likely to prove one of the greatest—if not the principal—industries in the province. Recent examinations by mining experts, prospectors, and others who were in a position to judge, have all been productive of highly favorable reports as to the richness and extensive character of the mineral deposits in Cariboo, Yale, Kootenay and other districts. In many places work has commenced and machinery has been placed in position. Capitalists have signified their intention of investing, and everything is now tending towards an extensive treatment of the mineral bearing rocks of the province, and especially of gold. Should results prove, as there is good reason to anticipate, the gold mining industry will branch into a permanent and lucrative one, and one that will hasten the progress of the province.—*Colonist*.

During the past season four strong companies have been engaged on McCullough creek. The Ophir Bedrock Flume Co. commenced work at the mouth of McCullough creek last summer, and have about three hundred feet of ground sluice constructed. Mr. Gray is delaying the clean up as long as possible in these works so that the preparations for putting in hydraulic power may not be interrupted. In the meantime they are starting a tunnel which will enable them to continue work throughout the winter. There is undoubtedly a considerable sum of money now in the Ophir Co's flume, as nuggets of good size have been picked out of the face frequently during the past few months. Indications show that bedrock is not far ahead, and Mr. Bray intends to have a "giant" with the other necessary machinery on the ground in good time to take advantage of the spring flow of water in the creek.

The Baldhead Co. are drifting in their claim a mile and a half above Gray's.

Above the Baldhead claim is the Erickson; their tunnel has been shut down during the close season, or until such time as the Selkirk company's tunnel (immediately above) has been pushed forward to bedrock, these two companies having arranged to co-operate in prospecting the Selkirk claim.

While undermining some coal, which a previous shot had failed to bring down, at No. 1 Esplanade shaft of the Vancouver coal company, a miner was lately crushed to death by the mass falling upon him.

We are informed by the *Critic* that notice has been given that letters patent for the incorporation of a joint stock company, to be called the Montreal Manganese Mining Company, for the

mining of manganese and other minerals in the County of Hants or elsewhere in the province, has been applied for pursuant to statute.

The chief place of business in Nova Scotia will be Maitland, and the intended capital stock is \$100,000, to be divided into ten thousand shares of ten dollars each.

H. T. Harding is solicitor for the applicants. The provisional directors of the company are to be H. T. Harding, David Andrews, and Thomas Ralph. The Hon. David McLelan, Provisional Secretary of New Brunswick, J. T. McBride of Montreal, and W. R. Stockbridge, broker of Boston, are prominent amongst the applicants.

Hants County is celebrated for its large deposits of manganese, and we are glad to note that a company with plenty of capital to work them will soon be in active operation. We are informed that the new company will purchase extensive manganese properties near the Shubenacadie River.

EASTERN TOWNSHIPS.

COPPER AND OTHER MINING PROPERTIES BELONGING TO MR. WM. FARWELL, SHERBROOKE.

DESCRIPTIVE NOTES BY CAPTAIN FRANCIS BENNETT MINING ENGINEER.

TOWNSHIP OF ASCOT.

The Pyrites region of the Township of Ascot, in the Province of Quebec, has proved to be one of the most important in Canada. The ore consists of Pyrites, containing from 3 to 4 per cent. Copper, and from 35 to 45 per cent. Sulphur. It occurs in veins in micaceous and chlorite slates, associated with silicious and calcareous matter. The discovery of gold and silver accompanying these ores gives additional importance to the region.

The properties in this Township, now offered for sale, consist of the following Mines and Mining Lands:

1st. CLARK MINE, Lot 11, in the 7th Range, 187 acres, in fee-simple.

This mine is situated towards the centre of the mining region above described. It has been somewhat extensively worked, and a considerable quantity of ore extracted. The principal mining work has been done by means of open cutting on a vein about 18 feet thick, and containing about $3\frac{1}{2}$ per cent. copper. Other veins are known to traverse the property.

The mine is about a mile and a half from the Lennoxville station of the Grand Trunk Railway, and $2\frac{1}{2}$ to 3 miles from the City of Sherbrooke.

2ND. SHERBROOKE MINE.—Part of Lots 12 and 13 in the 7th Range, 329 acres in fee-simple.

This mine immediately adjoins and is traversed by some of the same Pyrites veins as the Clark Mine, besides some others not embraced in that property. The Sherbrooke Mine property has been extensively explored at surface, but with the exception of a trial shaft (said to be 60 feet deep) it has not been opened up by underground workings. The value of the property is established by the known existence in it of wide veins of Pyrites of which one of the exploratory pits shows a vein of from 8 to 10 feet in width, of which a part yields over 5 per cent. metallic copper. Specimens from this vein are said to have also yielded, according to competent

authorities, from four to five dollars per ton of gold, eleven dollars per ton of silver, with from 35 to 40 per cent. sulphur.

This mine is a little over a mile from the Lennoxville station of the Grand Trunk Railway, and $2\frac{1}{2}$ miles from the City of Sherbrooke.

3rd. BELVIDERE MINE.—Part of Lots 9 and 10 in the 9th range; W $\frac{1}{2}$ Lot 10 in 8th range; 292 acres in fee-simple.

The general condition of the rocks and ores on this property are similar to those of the Clark and Sherbrooke Mines. The workings consist of a shaft, sunk 100 feet on a vein of between six and seven feet wide, rich in Sulphur, and yielding Copper Ores of from 3 to 4 per cent. of that metal.

The following is Sir William Logan's description of this Mine, as given in his general report for 1863, viz:—

"Here there is a considerable breadth of fine white micaceous slates, with which interstratified a bed of greenish quartz, or mica schist; this is in parts chloritic, or talcose, and contains large quantities of a mixture of iron pyrites, with yellow copper ore. Select portions of this gave, when dressed, one-half the weight of ore, which contained one-third of silicious matter, and 7.3 per cent. of copper, the remainder being iron and sulphur. The breadth of this bed is about six feet, and it is estimated that it will yield two tons of dressed ore similar to the above to the fathom."

Other Pyrites beds are known to exist on this property, which is situated from $2\frac{1}{2}$ to 3 miles from a railway.

At the time operations were suspended at the foregoing mines, the value of the sulphur in the ores was not recognized, and it was chiefly on account of its presence in large quantities that the mines were closed.

4th. ASCOT PROPERTIES.—Part Lots 12 in the 7th Range; 12 in the 8th Range, and 14 in the 8th Range; 171 acres, mining rights.

The bands of Copper-bearing rocks are known to traverse these properties, which however have not yet been developed by mining operations.

5th. MORRILL LANDS, as per accompanying list, 1,300 acres in fee-simple.

Originally taken up for Gold mining purposes, discoveries of that metal which were deemed important having been made on adjoining properties—apart from their value in this respect, they are heavily timbered, and would be found useful for the supply of firewood, and timber for use at the Mines.

The Waterloo and Magog Railway (in connection with the Vermont Central R.R.) passes through a part of this property.

TOWNSHIP OF ORFORD.

8th. CARBUNCLE HILL MINE, as per accompanying list, comprises 718 acres of land, in fee-simple.

This mining property is situated in the heart of a mineral region, which combines many of the most essential characteristics, both for the extensive deposition and profitable working of copper and other ores. The rocks consist of chloritic slate, serpentine and diorite, and the metallic veins occur towards the line of contact of these distinct varieties of rock. On the property referred to, several distinct and well defined veins or beds of yellow sulphuret of copper occur, and have been traced by exploratory works along the brow of a hill, elevated about 800 feet above the level of Brompton Lake, situated about half a mile to the east. A small opening on one of the veins, which crops out on the face of the cliff, shows a thickness of five feet, yielding a considerable quantity of yellow

sulphuret of copper of about 12 per cent. of that metal. No regular mining operations have been made on the property, but the copper-bearing veins are proved by surface explorations and by natural exposures to extend over a large proportion of it. The property is now about 11 miles from the nearest railway, but a railway—now projected, and most probably very soon to be constructed—will pass through it, or within a very short distance.

TOWNSHIP OF CLEVELAND.

9th. ST. FRANCIS MINE.—S. E. $\frac{1}{4}$ Lot 25, in the 12th Range; 50 acres in fee-simple.

On this very promising mine, which is situated about three miles from the Richmond station of the Grand Trunk Railway, a very considerable amount of mining work has been done, and with most encouraging results. A well defined vein, richly charged with vitreous purple and yellow sulphurets of copper, traverse the entire length of the property, or about half a mile, cutting chloritic slates, the gangue being a mixture of quartz and calespar. The vein is from three to five feet thick, and for a considerable length in the parts worked yielded an estimated average of two tons of 8 per cent. copper ore per fathom, (some portion being estimated to have yielded as much as one ton and a half of 40 per cent. copper ore per fathom). The plant on the mine consists of dwelling houses, smith's shop, ore sheds, office, etc., 1 large winding and pumping steam engine with boiler, winding and pumping gear, about 40 fathoms Cornish lifting pumps complete, railway tracks, ladders, etc.

TOWNSHIP OF GARTHBY.

10th. GARTHBY MINE.—A large block of lands, for the most part unexplored, comprising (as per accompanying list) an aggregate of 2,938 acres, in fee-simple.

On one of the lots comprised in this property, there appears to be a large bed or vein of Pyrites, the entire thickness in which the Pyrites are mingled with the rock being about twenty feet; on another lot and near the main road leading to the mine there is the outcrop of a vein of from 3 to 4 feet wide of solid Pyrites.

Samples of copper ore have been broken on this property that have yielded by assay as much as twenty-two per cent. of copper, while other samples were found to be free from copper. An analysis of the pyrites apparently free from copper, gave: sulphur 48 per cent., copper 1.1 per cent., iron 42 per cent., silica, etc., 8.9 per cent. As the ore contains such a large percentage of sulphur, it is peculiarly adapted for the manufacture of sulphuric acid.

The distance of the mine from the Garthby station of the Quebec Central Railway, (to which a tramroad could be cheaply made), is from four to five miles, and a railway is now chartered which it is expected will run through these lands.

ACTON.

11th. ACTON MINE.—Part Lot 32 in the 3rd Range; 100 acres in fee-simple.

This mine has proved to be one of the most productive and profitable in the Province of Quebec. Within three years after the mine was opened it had produced ores to the value of nearly \$500,000. The ore, which consists chiefly of the purple and yellow sulphuret of copper, is distributed throughout a thickness of from 200 to 300 feet of dolomitic limestone, and is occasionally found in masses of exceeding richness. From three of these masses 16,300 tons of 12 per cent. copper ores were excavated by open cut-

ting. This mine gave employment in 1861 to between 500 and 600 hands, and although its character as a good mine for permanent and profitable working has been very much impaired by the limited regard given to exploratory works, it is highly probable that the ore is still very far from being exhausted. Sir William Logan is reported to have said of this mine:

"Little has been done for discovery, and it cannot be said how near to the present floor of the mine may be found other masses similar to those that have been excavated."

This mine is situated about half a mile from the Actonvale station of the Grand Trunk and South Eastern Railways, about fifty miles from Montreal.

TOWNSHIP OF BROME.

12th. BROME MINE.—Part of Lots Nos. 2 and 3 in the 4th Range, 50 acres in fee-simple.

This property is situated in a region that has deservedly attracted much attention from mining investors. It is characterized by the occurrence of very thick and persistent embedded veins of rich sulphuret of Copper. The mine in question lies on the strike of some of the most important of these, and is in the immediate vicinity of a railway.

TOWNSHIP OF BOLTON.

13th. BOLTON MINE: As per accompanying list 400 acres in fee-simple.

This property is situated between that of the Huntington Mining Company on the south, and the Ives Mining Company on the north, occupying the space between these two properties, and traversed by the veins that have been so extensively worked in the Huntington Mine. About the middle of this property two shafts have been sunk on the vein, to a depth of between 60 and 70 feet. These shafts are connected at this depth by a drift, in which the vein is about six feet wide, composed principally of Iron Pyrites containing large patches of very rich yellow copper ore.

This Mine is about 2 miles from the Eastman Station of the Waterloo and Magog Railway.

TOWNSHIP OF CHESTER WEST.

14th SHAW MINE: As per accompanying list comprises Mining rights; total 630 acres.

Copper bearing beds, apparently of much importance have been discovered and partially developed upon this property. On one of these beds a trial shaft has been sunk to a depth of 40 feet, shewing a thickness of between two and three feet, charged with purple and yellow copper ore to the extent of 4 per cent. metalliferous band of rocks at this place is said to be from 40 to 50 feet, and it has been traced for about 500 feet. Other promising veins crop out in the property, but no regular Mining operations have yet been done on it.

15th. VIGER MINE.—As per list comprises Mining rights, total 1,255 acres:

This property is traversed by several copper bearing quartz veins in chloritic and micaceous schist, which, apart from the quartz veins yields rich vitreous copper bearing rock being about 170 feet. The principal vein has been exposed at surface, over a length of nearly half a mile by shallow pits, from which a considerable quantity of rich copper ore has been incidentally obtained. Two Adit levels, for which the ground is highly favorable, have also been driven to prove the veins in depth, with results that are represented as being highly satisfactory.

This mining property is about 15 miles from the Arthabaska station of the Grand Trunk Railway.

TOWNSHIP OF PORTLAND EAST,

COUNTY OF OTTAWA.

Continuation of the North Star Vein. Partly developed and shewing very high indications.

For particulars apply to

Dr. VALADE, Ottawa.

Or to the Office of the

CANADIAN MINING REVIEW.

Late Items.

NOVA SCOTIA.

Since the collapse of the Albion mine affairs have been quiet in the Montague District, but now comes news of a promising strike on the Montreal areas. A small lead has been proved and the quartz which was crushed at the Baker or Annand Mill proved good for 2 oz. to the ton.

The Oxford mine is looking well, and prospecting with most encouraging results is going on on the Anderson, Cogswell, and McKay areas. The richest leads seem to run into or through a swamp, which could be drained at small expense. These areas are held by parties who will not work them, and what the miners consider the best part of the district, good they say for millions, is now lying idle. The swamp could be drained for a few hundred dollars, and then all difficulty in working the properties would be overcome.

The following are the official returns for the month of January, so far as received at the Mines Office:

District.	Mill.	Tons.	Oz.
Whiteburn	Barber & Douglas Co.	25	16
East Rawdon	Rawdon	555	244½
Dar's Hill, Salmon River	The Dufferin	827	262
Lake Catcha	Oxford	49½	355¾

FOR SALE.

A No. 1

Prospecting Drill,

With new steel boiler and complete outfit.

Apply to

ROBERT GEE,

270 ST. JAMES ST., - MONTREAL.

**Notice to Contractors.**

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for New Examining Warehouse, &c., Ottawa," will be received at this office until Tuesday, 1st March, for the several works required in the erection and completion of the

NEW EXAMINING WAREHOUSE, ETC.,
AT

OTTAWA.

Plans and specifications can be seen at the Department of Public Works, Ottawa, on and after **MONDAY, 14th February.**

Intending contractors should personally visit the site and make themselves fully cognizant of the work to be done, according to the said plans and specifications, before putting in their tenders.

Persons tendering are further notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an *accepted* bank cheque made payable to the order of the Honorable the Minister of Public Works, *equal to five per cent.* of the amount of the tender, which will be forfeited if the party decline to enter into a contract when called upon to do so, or if he fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

A. GOBEIL,

Secretary

Department of Public Works,
Ottawa, 27th January, 1887.

**Notice to Contractors.**

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Ice, Public Buildings," will be received at this office until Monday, the 14th February instant, for filling the Government ice house at the Rideau Canal Basin, Ottawa.

Sealed tenders endorsed "Tender for Ice, Rideau Hall, &c.," will also be received at the same time for filling the ice house at the Governor General's Residence, Rideau Hall.

Tender to state price per block of the following dimensions, viz.:—3 ft. by 1 ft. by 1 ft., which price must include cost of packing and of the sawdust required for that purpose.

The ice to be measured before being packed in the ice house and payment to be made accordingly.

N.B.—The ice must be taken from the Ottawa River, above the Chaudiere Falls.

By order,

A. GOBEIL,

Secretary.

Department of Public Works,
Ottawa, 5th Feb., 1887.

**MINING REGULATIONS**

To Govern the Disposal of

Mineral Lands other than Coal Lands,**1886.**

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron, or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting, for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode, or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron, on veins, lodes, or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundry shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mines.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provide for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Lands Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of **FIVE DOLLARS**. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of **FIVE** years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than **FIVE HUNDRED DOLLARS** in actual mining operation on the same; but the claimant is required before the expiration of each of the five years, to prove that he has performed not less than **ONE HUNDRED DOLLARS** worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of **FIVE DOLLARS**.

The price to be paid for a mining location shall be at the rate of **FIVE DOLLARS PER ACRE**, cash, and the sum of **FIFTY DOLLARS** extra for the survey of same.

Not more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.—The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area, which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided, that should any person making an application purporting to be for the purpose of mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The Regulations also provide for the manner in which land may be acquired for milling purposes, reduction works, or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect of quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the **RIGHTS AND DUTIES OF MINERS** are fully set forth.

The Regulations apply also to

RED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The **GENERAL PROVISIONS** of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contain the *forms* to be observed in the drawing up of all documents, such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed-rock flume Company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulation to govern the disposal of Dominion Mineral Lands, the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

A. M. BURGESS,

Deputy Minister of the Interior.

The Intercolonial Railway of Canada,

THE ROYAL MAIL PASSENGER AND FREIGHT BOATS BETWEEN CANADA AND GREAT BRITAIN.

G. POWELL,

Under Secretary of State.

Ottawa, 19th Feb., 1886.

DEPARTMENT OF INLAND REVENUE.

An Act respecting Agricultural Fertilizers.

THE public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886, and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:—

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the said fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel, or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue, and the provisions of the foregoing sub-section have been complied with.

Every person who sells, or offers or exposes for sale, any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale, any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells, offers or exposes for sale, any fertilizer which does not contain the percentage of constituents mentioned in the manufacturers' certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always, that deficiency of one per centum of the ammonia or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and intitled "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIAL,

Commissioner.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned and marked "Tender for a Timber Berth," will be received at this Office until noon on Monday, the 1st day of November next, for four timber berths of ten square miles each, more or less, numbered respectively 4, 5, 8 and 9, situated on Kicking Horse River and Ottertail Creek, a tributary of the Kicking Horse River, near Field and Ottertail Stations, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately of these berths, together with the conditions on which they will be licensed, may be obtained at this Department or at the Crown Timber Offices, Winnipeg, Calgary, N. W. T., and New Westminster, British Columbia.

A. M. BURGESS,

Deputy of the
Minister of the Interior.

Department of the Interior,
Ottawa, 14th August, 1886.

Tenders for a License to Cut Timber on Dominion Lands in the Province of British Columbia.

SEALED TENDERS addressed to the undersigned, and marked "Tender for a Timber Berth," will be received at this Office up to noon on Wednesday, the 1st day of December next for three timber berths of fifty square miles each, more or less, numbered respectively 16, 17 and 18, situated on the west side of the Columbia River, near Golden City Station, on the line of the Canadian Pacific Railway, in the Province of British Columbia.

Sketches showing the position approximately, of these berths, together with the conditions upon which they will be licensed, and the forms of tender therefor, may be obtained at this Department or at the Crown Timber Offices at Winnipeg, Calgary, N. W. T., and New Westminster, British Columbia.

NOTICE RESPECTING PASSPORTS.

PERSONS requiring passports from the Canadian Government should make application to this Department for the same, such application to be accompanied by the sum of four dollars, in payment of the official fee upon passports as fixed by the Governor-in-Council.

G. POWELL,
Under Secretary of State.
OTTAWA, 19th Feb., 1886.

Department of Inland Revenue.

An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue and the provisions of the foregoing sub-section have been complied with.

Every person who sells or offers or exposes for sale any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always that deficiency of one per centum of the ammonia, or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and entitled, "*An Act to prevent fraud in the manufacture and sale of agricultural fertilizers*," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALI,
Commissioner.

Hartsfeld Transportable Water
Jacketed Smelting Furnace, Metal
Dust Condenser and a Separator
Crucible, manufactured by the

HARTSFELD

Portable Smelting Furnace and
Mining Co.,

NEWPORT, KENTUCKY, U.S.A.,

In sizes from 5 to 60 ton capacity, and by the following licensed manufacturers on Royalty.

IMRAY & CO., London, Eng., and Melbourne, Australia.

F. A. HUNTINGTON & CO., Chihuahua, Mexico.

PARKE, LACY & CO., Auckland and Chili, S.A.

W. T. GARRETT & CO., San Francisco, Cal., for the Pacific Coast.

McILVAIN & SPIEGEL, Cincinnati, Ohio.

Letters Patent have been secured in all principal foreign countries, and are sold in shares, trade, royalty or otherwise. Run your eye over this and return answer: silence means no! Catalogue free.

This furnace requires no more care or attention than an ordinary steam boiler, and can be ran as long and with as little loss of time or expense for repairs. Full information will be furnished by the

Hartsfeld Portable Smelting Furnace
& Mining Co.

Reduction Works, No. 90 and 92 Thornton St.

MINES AND MINERALS.

Developed and Undeveloped Mines and Minerals of Commercial Value Bought and Sold.

Properties examined and analyses made of ore of every description. A competent Expert is permanently engaged for the purpose of making Unprejudiced Reports on all Mines placed in our hands for Sale, such reports being at all times open to intending purchasers for examination.

Phosphate, Iron, Iron Pyrites, Copper, Asbestos, Mica, Plumbago, Gold and Silver Mines, and Marble and Sandstone Quarries for Sale.

Mineral lands examined and reported on by our expert; also, analyses of Minerals of every description made by a COMPETENT ASSAYIST.

Correspondence with Owners of Mines and Capitalists desirous of investing is most respectfully solicited.

Address all Communications to

E. G. POWELL, 14 Metcalfe Street, Union Chambers, Ottawa, Canada.

Canadian Mining Review,

OTTAWA.

PUBLISHED MONTHLY.

ANNUAL SUBSCRIPTION - - - - - \$1.00

ADVERTISING RATES - - 15c. per line (12 lines to 1 inch).

OFFICE:

UNION CHAMBERS, 14 Metcalfe St.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 20th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Advertising Space.

The circulation of the CANADIAN MINING REVIEW, which has steadily been going up since its first publication, more than five years ago, has now more than doubled the estimate upon which we had reckoned, and its value as an advertising medium to business men who wish to reach the best classes of mine owners and operators, and the mining centres and camps of every province in the Dominion, is consequently very greatly enhanced. The REVIEW is in the widest sense a Canadian journal belonging to all provinces alike; it is the only journal published in Canada wholly devoted to the interests of her mining industries and mineral resources. We would simply draw the attention of those who have hitherto overlooked it, to this matter, promising our best attention and most reasonable terms on any application for advertising space.

TIMBER AND MINES

Of the Provinces of Quebec and Ontario as a Means of Producing Revenue.

John Stewart, Ottawa.

The timber area of these provinces is being lessened each year by fire and the axe to an extent beyond that which it is yearly increased by the renewing of the capital stock by the natural growth of the forest. The timber is considered such a permanent means of revenue that in selling lots of land certain reserves of timber are made by the local authorities, and the settler or farmer is not trusted as a fit and proper custodian of this source of the country's wealth. Timber lots are, however, sold to lumbermen or speculators out of the area included in a timber limit; he, therefore, is considered a proper person to hold the timber

reserves of the Province for his future use, and possibly to control the price of lumber or prevent it falling into the hands of a competitor in the same line. The timber area so held is very large, amounting to millions of acres of the best timber lands in these Provinces. The yearly decreasing supply of timber is accompanied by an almost yearly increase in value, not to the revenue and capital account of the Province, but to the fortunate owners of the lots so purchased. As a result of the custom of selling lots with timber, any increase in value of the capital or reserve stock on hand goes to the benefit of the holder of it on speculation; whereas, that benefit would go to the Province, if not sold, but was retained for lease as it ought to be.

Mining lands are sold at prices ranging up to \$2.00 per acre, in Ontario, and up to \$2.50* per acre, in Quebec, and no reserves of minerals are made, excepting for gold in Quebec. This industry is not considered of sufficient value to be held as a means of revenue. In consequence of the system of selling minerals along with the soil, the farmer or speculator in mining lands becomes the person who holds this source of national wealth and revenue; whereas, the mining right and mining lands ought to be held for the use of the miner by the Provincial authorities. A glance at the manner in which mining lands are secured will show the want of system, and the injustice done to explorers and prospectors, where a party under the present system, now in force, makes application at the Department of Crown Lands for a larger or smaller area of mining lands, and no notice of such grant, or location, its area, or time of option, or period of exploration, is made, either on the ground or in the Local Land Office, or in the local newspapers of the district in which the location is made. A party, or speculator, applies for the unoccupied lands in half a township, or a whole township, or possibly more; he may make a money deposit or not, according to the influence he possesses, with the "powers that be." He may explore the lands or not, it is not compulsory for him to make a report of such exploration; nor does the Land office acquire any information of the nature of the part not accepted from the option so granted. There being no law, regulating his actions, he may do just as he pleases in the matter. Sundry explorers and prospectors, as A, B and C are at work in this district, in which the option has been granted, and are of course ignorant of its existence, and prosecute the search for the hidden treasures they are in quest of, quite ignorant of the sad fact that the Government under the present (to them dishonest) system will only rob them of any discovery they may make. Having made a discovery, or find of minerals, A, B or C, makes application for one or more lots, and receives a reply to the effect that the lots in question have been applied for by Mr. Speculator! Mr. Speculator is also notified, and either accepts

the lot or lots, on the exploration or reputation of A, B or C, if it is good, or sends quietly to have it looked at, and if good, resolves to take it, and as A, B, C are not entitled to make their own location on the ground, as it ought to be, consequently there appears no irregularity in the manner in which the transaction is completed, in favour of Mr. Speculator, who has stolen the discovery. A, B or C, the actual discoverer, or the person entitled to it, has no redress, unless he shares his claim with an influential political friend or two who will champion and fight his cause.

Is this a just and fair system to the mining section of the population? Is it a wise system that scatters the capital or revenue earning resources of the Province, and disposes of them at the price of, and along with the soil, to the wrong owner?

On the one hand the Province offers inducements to immigration, and under a wrong system of laws renders the Province an unfit place for the location of a mining population, as the laws now in force do not encourage exploration and deprive the worthy discoverer of minerals of the just reward of his labour.

In discussing the desirability or not of Government control of certain matters, some do not discriminate or appreciate the difference between cases which are not parallel. In one case, there is an ownership or proprietary, by the state, for the general good, of an article which is tangible and real, such as land, minerals or money, and mail matter; in these cases there is an ownership or responsibility on the part of the State, as these things constitute matters of national magnitude and importance, and prevent monopoly and frauds under proper regulations, thus giving better public satisfaction and confidence than when in private hands. In the instance of others, which are purely matters of trade, with no vested interests in that which is tangible, and no ownership, trust or charge is placed with the Government, but merely a trade, or business conducted, and has no material existence is liable to change of value or subject to inflation in price, and that cannot be manufactured or made, having no reality other than mere sentiment, or the product of the brain of man, as in the case when the state controls the schools and religion; these two, had best be left in private hands to permit of the full development of the individual capacity and competition, producing the survival of the fittest, or that conducted under true principles of right and truth. The condition of Mexico is an instance of the above line of argument. The Government of that country controls the mining industry and owns all minerals, and mining has consequently prospered and been the chief means of revenue.

With forests fast decreasing in area, and mining resources ruined or undeveloped, and the system goes on as at present, from what source in the future is the Provincial Revenue to be derived?

The large extent of mining territory of known, and in part some of it yet unknown value, that these Provinces still hold, intersected as it is by lines of railway, and the benefit of it to be derived from the active development of that wealth to the country at large, but more especially to the settlements in and around the various mining locations, renders the enactment of a better system of mining laws and inspection a necessity which cannot longer be delayed.

[*By an amendment passed by the Lieutenant Governor in Council, 10th December, 1885, it is ordered under the provisions of section 124, of the Act 43-44 Vict., Chap. 12, (Quebec General Mining Act of 1880), that in all future sales of lots of land in the Province of Quebec, for mining purposes, the following prices be exacted :—

For phosphate lands, five dollars (\$5) per acre, as at present.

For iron and ochre, two dollars (\$2) per acre.

For all other mining lands including gold, silver, asbestos, lead, mica, graphite, plumbago, copper and generally all mines other than iron and ochre, five dollars (\$5) per acre.]—Editor.

PHOSPHATE.

The Latest Quotations.

MINERAL PHOSPHATES—Some transactions have already taken place in Canadian at about last year's prices, but Raisers are not prepared to do further business at present without an advance for the best qualities. Ground Canadian is also enquired for, but sellers are indisposed to contract until the season for shipment draws nearer. South Carolina Phosphates.—There is no new phase to report; a large contract from a new deposit of land has been made at 8d. for delivery to a safe port in U. K., and sundry ballast parcels have realized from 7½d. to 8d. according to port of discharge. The new Somme Phosphate continues to turn out satisfactorily, and is being eagerly sought after by both Home and Continental Manufacturers to such a degree that we have had to decline any but small trial orders for prompt shipment. Belgian.—A large contract in low class material has been made to close a liquidation account, otherwise the business transacted has been at late prices, which still remain temptingly cheap for this useful material. A new make of 45 to 50 per cent. and 50 to 55 per cent. both with a guaranteed maximum of 2 per cent. Iron and Alumina, is being offered which may supersede the old ferruginous quality. Cambridge and Bedford Coprolites are unchanged, and quoted at 43s. f.o.r., or Ground at 50s. in Buyer's bags, or 52s. in lent bags, f.o.r., the latter at 26s., f.o.r., or 31s. 6d., f.o.b., Thames.

Township of Loughboro'.

Mr. J. Sloan, of Perth, is prospecting on the Purdy Bros. lots. Operations will be begun as soon as the snow is off the ground.

Satisfactory reports have been received from Messrs. Smith & Lacey's deposit in the same township.

During the present existing depression in the phosphate market but a few hands are employed at the Foxton property, in the Township of Loughboro'. The present depth of the shaft is about 70 feet, and drifting is being pursued in a north-easterly direction from the bottom on a capital vein of pure ore. The indications are most encouraging.

Buckingham District.

The Du Lievre Company are making improvements at the basin below Buckingham. They anticipate a brisk business in the spring.

The construction of the new tram line at the Little Rapids mine is nearing completion. This line, which is already graded, runs from the workings on the summit of the hill to the wharf at the river side. The transportation of the ore by this means will be accomplished in a couple of month's time.

The output from this property during the past month was about 115 tons of high grade ore. Mr. George Smith, the superintendent of the mine, states that he can mine ore in pit No. 2, for a considerable less price than from the bottom of the shaft where last month's product was raised. He says that with 50 to 70 men he can lay the ore at the river's bank for about \$5.00 per ton and not work off vein II.

The property is now thoroughly equipped with first class plant of the most modern and approved pattern, and the quality of the ore is of a very high grade. "Dr T. Sterry Hunt has said that from present appearances, in my opinion, no property on the Lievre offers better or surer prospects for extensive and remunerative operations than does this mine."

South Carolina.

2,775 men were employed last year in mining phosphate in South Carolina.

Nova Scotia.

The yield of gold at the Oxford mines for the month of February was 341 ozs. from 78 tons.

The annual meeting of the stockholders of the Acadian Coal Company will take place at New York, on Wednesday, 23rd instant.

Work has been resumed in the 100 feet shaft at the Cowan Gold Mining Company property, Yarmouth Co. A milling of about 10,000 lbs. of dirt taken from the new discovery is reported to have given about 3 ozs. of gold.

The shares of the Georges River Mining and Manufacturing Company, a West Virginia corporation which holds a Government lease of one square mile of mining area at Georges River, near North Sydney, Cape Breton, are at present on the New York market. The veins that have been discovered on the property are:—First, vein of grey magnetic iron 20 feet wide at surface. Second, vein of silver and other metals 20 feet wide and carrying ten ounces of silver at surface. Third, vein of iron pyrites, copper and other metals, samples of which taken from cut about 15 feet deep, carry about 10 per cent. of copper, besides other minerals, and strong indications of silver and gold.

The strike of the Pictou coal miners which, it was reported, had been settled, unfortunately still continues, and Halifax is at present suffering from a coal famine that is particularly hard on the poor, who have been unable to lay in enough coal to last through the spring. We have not examined into the cause of the strike, and so are unable to pronounce upon its merits, but, for the sake of the Halifax poor, we hope that it may be brought to a speedy termination. Cargoes of coal are now being received from Baltimore. Dealers in Sydney coal have evidently been taken by surprise, and will hardly let another season go over without greatly increasing their winter supply. The completion of the railroad to Sydney will put an end to all possibility of our coal merchants being caught in this way again.—*Critic.*

At the North Brookfield mine, Queen's County, the work of development is being vigorously pursued. Four shafts have been sunk, one to the depth of 80 feet, and cross levels have been run for at least 300 feet.

Reduced rates for transportation over the Inter-Colonial are wanted by the iron miners in this province. At present the cost of transportation from Nova Scotia to Ontario is about equal to the cost from England to the same market; so that the protection given by the National Policy to Nova Scotia iron mines is lessened by the extra cost of transportation from the mines to the market.

New Brunswick.

The gold mining areas at Eagle Lake, Salmon River, owned and operated by Messrs. Hattie & Ross, have been bonded to English capitalists.

Quebec.

The annual meeting of shareholders of the Intercolonial Coal Mining Company was held at Montreal on Wednesday, 2nd March. The following were elected directors of the company for the ensuing year:—Messrs. Gilbert Scott, H. A. Budden, James P. Cleghorn, Robert Anderson, Alexander Gunn, Peter Redpath, W. M. Ramsay, Henry J. Tiffin and H. S. Macdougall. At a subsequent meeting of the board Messrs. Gilbert Scott and H. A. Budden were re-elected president and vice-president, respectively, and Mr. W. J. Nelson was re-appointed secretary-treasurer of the company.

Ontario.

The annual general meeting of the British and Canadian Mica and Mining Company (Limited), was held in their offices at Ottawa on the 17th ult. The following gentlemen were elected office-bearers for the ensuing year:—President, B. A. Buxton, Esq., of London, England; Vice-President, C. W. Spencer, Esq., Montreal; Secretary-Treasurer, W. A. Allan, Esq., Ottawa.

The various reports presented showed that the property was in a most flourishing condition, and that the output of mica from the mine and the demand for it, both in Canada and in the United States, during the past season, had been eminently satisfactory. The demand for the product had more than trebled since the last meeting of the company.

Increased facilities, including new steam power for the breaking up of the ground, have been added to the property, and among other machinery a couple of Ingersoll drills, worked by compressed air, are kept constantly in opera-

tion. The quality of the mica is Muscovite of pure transparency and lustre, and the quantity in sight is apparently unlimited.

There is no reason why this corporation should not become one of the best dividend paying concerns in Canada. At present the indications are most satisfactory. An old miner has given it as his opinion that the property is capable of producing more fine mica than all the mica mines of North Carolina. From what we have seen of the property we can heartily endorse his opinion.

PORT ARTHUR DISTRICT.

Sixty men are at present employed at the Silver Mountain Mine.

A thirty stamp mill will shortly be placed in operation at the Beaver Mine. This will virtually double the mills.

Machinery is to be put in at the Malaga mine as soon as the spring opens. About ten men are presently at work.

Mr. T. A. Keefer has received instructions to commence work on both the Huronian and Huron Bay gold mines. Operations will be resumed at once.

The capital stock of the Shuniah Weachn Mine Company, which has recently been organized in London, to develop the Silver Mountain Mine, is placed at £100,000, shares £1 each. The vendors receive 25,000 shares and £30,000; 9,000 fully paid up shares is to be allotted to directors in lieu of remuneration for two years. The property which is situated about 10 miles west from Port Arthur is 240 acres in extent.

The *Miner* reports that the Rabbit Mountain Mining Company has given instructions for the erection of a smelting plant for the purpose of reducing their ore into silver bricks. No more concentrates or ore will be shipped out of the district from this mine, and it is one of the best signs of substantial progress chronicled for many a day. At the last meeting of the board of directors of this company the sum of \$20,000 was set apart to continue the work of developing the mine.

Judge Ingraham, of the Superior Court, New York, has given judgment in the action against the Silver Islet Consolidated Mining Company, brought at the instance of Theodore C. Weeks, Boston. From his decision it appears that the circumstances under which the stock of the company was issued in this case was a ingenious device for the purpose of evading the provisions of the Act. After reviewing at length the nature of the case and discussing the question of the assessments and forfeitures, the judge said: "On the whole case I think that the plaintiff is entitled to judgment; that on payment of the amount due on the assessment within thirty days after the entry of judgment, with interest from the date when the assessments respectively became due, the plaintiff shall be relieved from the forfeiture."

LAKE OF THE WOODS DISTRICT.

Messrs. Dobier & Co., of the Pine Portage Mine, will resume operations on their property shortly. Some difficulty has been experienced as to the most economical method for the

treatment of their ore, but it is expected that a steel furnace will obviate the difficulty. The ore though refractory is said to be rich.

The Gold Hill Mining Company expect to commence work at an early date. With the exception of some surface prospecting work and the sinking of some forty feet of a prospecting shaft but little work has been done so far on the claims.

North-West Territories.

Coal is reported to have been found within easy distance of Battleford.

At a recent meeting of the directors of the Canadian Anthracite Coal Company, held at Ottawa, the general manager reported that operations are now being conducted on seam No. 6, which was found to be five feet three inches thick. The deposit in this seam is found to be much harder and superior to the others so far operated on. One hundred men are in camp and ninety-three of these are on the regular pay roll of the company.

British Columbia.

During the year 1886 twenty accidents to persons employed in or about the collieries have been reported. Of these three were fatal.

The output of coal from 1874 to 1886 has been as follows:—1874, 81,000; 1875, 110,000; 1876, 139,000; 1877, 154,000; 1878, 171,000; 1879, 241,000; 1880, 268,000; 1881, 228,000; 1882, 282,000; 1883, 213,000; 1884, 391,070; 1885, 365,000; 1886, 326,636.

The Burns Mountain Quartz Mining Company have, during the greater portion of last season, had men at work running drives in search of the main lode on their property in Cariboo. Over eight hundred feet has been driven and the indications are considered good.

The value of gold exported by the banks of Victoria during 1886 is placed at \$750,043. This shows a bank export of nearly \$160,000 in excess of 1885, and adding one-fifth as the estimated value of gold leaving the province otherwise than through the Victoria banks, gives a total yield of over \$903,000 for the past year—a very substantial and gratifying increase.

The following gentlemen have been elected office-bearers of the British Columbia Milling and Mining Company for the ensuing year:—Directors: Hon. J. H. Gray, J. Earle, F. S. Barnard, C. E. Redfern, J. Heywood, J. Irving, and J. Grant. W. J. Heywood was elected president, W. C. E. Redfern, treasurer, and Mr. G. A. Sargison, secretary. The auditor of the corporation is Mr. G. A. Sargison.

Cunningham Creek, where the ubiquitous Chinese made a lucky strike during the summer, and a company of four men has been taking out from \$20 to \$50 a day to the man, is said to be, on investigation, a discovery of no great importance. The location being on a point across which the old bed of the creek passed at a much higher level than the present bed of the stream.

The remarkably dry season together with a further decrease of the population in the Cariboo district has had the effect of further diminishing the annual yield of gold. Mr. Bowron states that the product of the past year is per-

haps not less than in 1885, in proportion to the number engaged and the time consumed in working, as for a considerable portion of the year quite a number of white men have been engaged upon quartz ledges which are, as yet, non-productive; besides, not a few miners left the district in the spring for the Granite Creek mines.

The Forest Rose Company of Cariboo, which yielded largely as a drifting claim in years gone by, and which has been at great expense for the past six or seven, in opening up so as to work as a hydraulic claim has at last reached bed-rock with their cut, and during the past season have been rewarded with good pay. The commission think that this claim will yield good returns for the next fifteen or twenty years as the extent of their ground is large.

Mr. Bowron, Gold Commissioner for the province, in his report to the Minister of Mines, estimates the gold yield for the district of Cariboo for the past year as follows:—

Barkerville Polling Division.....	\$96,000
Lightning.....	54,800
Quesnelle Mouth.....	45,800
Keithley Creek.....	62,000
Amount from time of collecting statistics to December 31st.....	15,000
Amount of which no account was obtainable.....	15,000
Total.....	\$288,300

Mr. J. L. Crimp, in his annual report, gives the following particulars of the work done during the past year:—"There have been fewer white miners in the district this year than last, but more Chinese; and it is chiefly owing to them that the increase in the yield of gold has taken place, and if it had not been for the continued rains during the month of September, the increase would have been considerably larger. During that month the several creeks were very high, and in consequence carried away many of their wing-dams, thereby causing a severe loss to them. Although these creeks have been worked over—some portions of them two or three times—the Chinese, by their excellent management and industry, are enabled to take out small wages. On Dease Creek, the increase was the largest. More Chinese were on that creek than any of the others, and most of them worked in the bed of the stream. All of the white men on the same creek have been working in the hills, and some of them have done very well; and the same may be said of the other creeks, for the beds of those streams having been worked over so many times, there is no inducement for the white miners to open claims in the old worked out creeks.

"The yield for this past season, as far as I can ascertain, is as follows:—

Laketon Division.....	\$41,460
McDame Division.....	22,150
Total.....	\$63,610

"There has been but little prospecting done in this district the past summer. There has been four white men prospecting on Mosquito Creek the past year, and although they have found very encouraging prospects, they have not found gold in sufficient quantities to pay; but are still in great hopes of striking good pay when they reach more favourable bed-rock, for the rock is so hard and smooth where they are working that it is impossible for gold to lodge. There were also three white men, Messrs. Hil-

ton, Sainsbury and Beedy, prospecting on the Muddy River, a large stream to the east from the present mining district, situated about ninety miles east of Sylvester's Landing. The stream is a large one, running through a very wide valley, and emptying into the Laird River, about eighty miles below Mr. Sylvester's trading post. Mr. Hilton informs me that if it had not been for the high state of the river, he thought they would have done very well. In consequence of the high water most of the bars were covered; but wherever they found bars, at the head of them they prospected very well. On one occasion, two of them rocked out \$100 in one day; and on another, one man rocked out \$140 in seven days. The character of the gold is fine, and has to be saved with quicksilver. In 1874, there were eight men on the same river, some distance above, where the mountains come much closer together, and I have been informed by one of the parties a few days ago, that they found coarse gold, which he thought would pay five dollars per day; but at that time wages were eight dollars per day on Dease Creek, so they concluded that it would not justify them to remain there. He tells me, also, that he thinks the distance from Dease Lake to where they got these prospects is from 90 to 100 miles, in an easterly direction from Dease Lake. Taking into consideration the excellent prospects found on the bars, of fine gold, it leads to the conclusion that its source is in the mountains. I would strongly recommend that the Government make a small appropriation to assist, say three or four men to get an outfit next summer to proceed there and prospect this stream, or creeks emptying into it, for unless some new discoveries are made, this district will be soon reduced to a very small number of miners. The number of men wintering in the mining portion of the district is 29 white men and about 70 Chinamen. The health of the miners during the past season has been generally good, and good order has prevailed all over the district."

United States.

Mr. James M. Swank, Secretary of the American Iron and Steel Association, estimates the consumption of pig iron in the United States for the past twelve years as follows:—

Year.	Gross Ton.	Year.	Gross Tons.
1874	2,500,000	1881	4,982,565
1875	2,000,000	1882	4,963,278
1876	1,900,000	1883	4,834,740
1877	2,150,000	1884	4,229,280
1878	2,500,000	1885	4,348,844
1879	3,432,534	1886	6,208,656
1880	3,990,405		

If we may judge from the old fashioned method of bringing round asphyxiated miners in the early days of English coal mining, Choke damp must have been a source of sore trouble to the miners, for the remedy, we are told, "was to dig a hole in the earth and lay them on their bellies with their mouths in it; if that failed they turned them full of good ale; but if that failed the case was concluded desperate indeed."

CALIFORNIA.

The product of the Plymouth Consolidated Gold Mining Company during the year 1886 was as follows:—January, 55,683.47; February, 45,611.11; March, 53,897.81; April, 50,778.91; May, 49,502.13; June, 44,166.43; July, 44,566.75; August, 51,528.16; September, 51,812.36; October, 56,513.95; November,

61,449.52; December, 61,467.80. Total, \$670,059.85. The average monthly product was \$54,555.92½. This is said to be the best gold mine in America, it is fully developed with large reserves, and is now paying larger dividends than any other similar property in North America. The stock is selling at about \$1,650,000. The company is said to possess the largest quartz mill in the world, with a single exception. From the printed report just published, it is stated that a piece of rock one foot square and one mile in length represents the amount crushed by the Plymouth mills every 24 hours.

The bill appropriating \$30,000 for a State Mining Bureau has been finally passed by a vote of 32 to 5.

Great Britain.

THE SCOTCH MINERS' STRIKE.

Recent English exchanges report a great labour demonstration, held at Edinburgh, at which it is computed about 10,000 persons were present. The main object of the gathering was to express sympathy with the miners of Scotland in their existing position; and resolutions were adopted calling for the nationalisation of land, mines, machinery, and all means of production for the common good. In order fully to appreciate the meaning of these resolutions, it is to be borne in mind that in Scotland alone there are between 60,000 and 70,000 miners, of whom about 30,000 are located in Lanarkshire, the remainder hailing principally from Ayrshire, Fifeshire, and the Lothians. In Lanarkshire the men have returned to their work discontented, and in Ayrshire the 7000 miners on strike have been recommended to go back to the pit "in the meantime," and pending the result of the forthcoming Conference. It is more than hinted—and the tone of the speakers bore out the inference—that should that Conference fail a national strike will ensue. In the west country wages have fallen as low as 3s. per day, while in the east the rate varies from 3s. 9d. to 3s. 11d. for eleven days' work in the fortnight. But from these sums have to be deducted, on an average, about 2s. a week for pick-sharpening, powder, oil, medical officer, &c., with the result that the West wages average 12s. 9d., and in the Lothians about 18s. weekly. It was pointed out, that a miner, while he got only 4½d. or 6d. for raising a ton of coal, paid 6s. to his master for it at the pit-mouth if he wanted to give warmth to his family; that the fines and charges imposed upon him in a day were often more than the total amount of his earnings; and that the net result of all this was starvation to the men and unlimited wealth to the masters, who, in many cases, spent their ill-gotten gains abroad in gambling, or at home in luxury. "In fact," said one speaker from the West, "unless the miners have their grievances redressed they are determined to make a desperate movement which will shake Scotland from one end to the other."

During the year 1886, 116 persons lost their lives from mining explosions in England and Wales. Since the Mines Regulation Act came into operation in 1873, there has been a marked diminution in the number of lives lost owing to explosions.

On 1st March there were 377 furnaces working and 506 idle throughout the United Kingdom.

COAL MINING.

Report of the Minister of Mines of British Columbia.

The Government Inspector's Interesting Figures—
Work Done During 1886 at the Various
Collieries.—Most Encouraging Prospects.

The report for 1886 of the Hon. John Robson, Minister of Mines in British Columbia, is just to hand. It is a capital resumé of the work done at the various mines, and is replete with valuable statistics and other information. The following is an excerpt taken from the report of Mr. Archibald Dick, the Government Inspector of Mines:

NANAIMO, B. C.,

1st February, 1887.

"SIR,—I have the honour to lay before you my report as Inspector of Mines, for the year ending 31st December, 1886, as required by the 'Coal Mines Regulation Act, 1877.'

"The collieries operated in the year 1886, are the following:—

"Nanaimo Colliery, of the Vancouver Coal Mining and Land Company, Limited.

"Wellington Colliery, belonging to Messrs. Robert Dunsmuir & Sons.

"East Wellington Colliery, owned by R. D. Chandler, Esq., of San Francisco.

"There has not been any work done at the Alexandria Colliery, which was started in 1884, in Cranberry District, by the Esquimalt and Nanaimo Railway Company.

"The output of coal for the year 1886 amounted to 326,636 tons, as follows:—

Nanaimo Colliery.....	112,761 tons.
Wellington Colliery.....	185,846 "
East Wellington Colliery....	28,029 "

Total output in 1886.....	326,636 "
Add coal in stock 1st January, 1886.....	25,653 "

Total coal for disposal
in 1886.....352,289 "

The exports of coal for the year 1886 amounted to 249,205 tons, as follows:—

Nanaimo Colliery.....	79,637 tons.
Wellington Colliery.....	144,526 "
East Wellington Colliery....	25,042 "

Total exports for 1886..249,205 "

"This quarter of a million tons of coal was shipped principally to California, but shipments were also made to Portland, Oregon; Alaska, Petropavloski, Mexico, and the Hawaiian Islands; besides which, coal for fuel has been regularly supplied to the ocean mail steamers, gunboats, and vessels calling.

"In order to arrive at the total amount of sales for the year, the sales of coal for use in this Province must be added to the tonnage of the exports; but as these local sales are included

in the returns of coal under the heading of 'home consumption,' aggregating \$5,787 tons, which comprises the coal consumed in the colliery furnaces (excepting in the East Wellington return), I can only refer you to the returns.

"The following comparison of the aggregate output and export of coal for the years 1884, 1885, and 1886, will give at a glance an idea of the fluctuating character of our coal operations:—

	Output.	Export.
1884.....	394,070 tons.....	306,478 tons.
1885.....	365,596 ".....	237,797 "
1886.....	326,636 ".....	249,205 "

"From the above it will be seen that the output of 1886 is below that of 1884, and 1885, considerably below the former; and, also, that the exports of 1886, while exceeding that of 1885, is far less than that of 1884.

"The year 1884 was one of unprecedented prosperity in our coal industry, both in volume of trade and prices realized; but the drooping figures of the succeeding years, with the lower rates which our collieries have had to submit to in return for their product, urge me to again bring before your attention the necessity for the adoption of some active measures for the relief of our collieries from the imposition of 75 cents per ton levied in the United States upon our coal when it enters their ports. With the removal of this inequitable tax by a judicious reciprocity treaty, our coal industry will at once recover itself, and years unexampled in activity and progress will become our happy lot. We begin the year 1887 with 25,653 tons of coal 'stock in hand' at the collieries.

"The following statement shows the position of British Columbia in the chief market for the produce of our mines for the past four years, and according to the outlook the position of our Province as an exporter to California will be fully maintained during the year 1887:—

	1883. Tons.	1884. Tons.	1885. Tons.	1886. Tons.
British Columbia.....	128,503	291,546	224,298	253,89*
Australia.....	174,143	190,497	206,751	247,293
England and Wales.....	131,355	168,808	170,656	160,869
Scotland.....	21,942	21,143	20,228	19,795
Eastern States (Anthra- cite, &c.).....	43,861	38,124	29,834	19,517
Seattle.....	139,600	125,000	75,112	57,552
Carbon Hill.....	149,135	122,069	157,241	124,527
Green River and Mount Diablo.....	76,162	77,485	71,615	90,664
Renton, Newport and South Prairie.....	43,600	60,413	67,604	73,674
	899,301	1,355,076	1,023,339	1,087,697

"It will be seen that the importations of the State of California in 1886, were larger than for any previous year; the market there for coal is steadily increasing in capacity for absorbing our product, which is a most encouraging feature in our future prospects.

"Our collieries are equal to the supply of coal of first-class quality for steam, gas, or household purposes, sufficient in quantity to meet the requirements of all markets at present within our reach; with harbour accommodation, wharves, and dispatch in loading, second to none.

"We are looking also to the establishment of the great ocean mail service between this Province and Australia, China and Japan, as introducing an additional customer for our superior coal, and I trust our expectation in this respect will soon be realized.

NANAIMO COLLIERY.

"This colliery, as has been the case with all

the other collieries in this district, has not been worked very steadily during the past year, on account of the dullness in the coal market.

"The Douglas Pit and the New Douglas or Chase River Mine, have 'stopped working,' and the machinery, rails, and dumps are all taken out. These mines are now filling, or are full of water.

"No. 1 Pit, Esplanade, Nanaimo.

"This is a mine mentioned in a previous report, and belonging to the Vancouver Coal Mining and Land Company (Limited). Everything about this mine, both on the surface and underground, is done in the strongest and most workmanlike manner. The workings about the bottom of this shaft having been already reported upon by me, I need not again describe them.

"The level on the south side of the shaft is yet standing idle.

"The level on the other side, known as the North No. 1 Level, has not been working steadily during the past year, except when it was necessary to make repairs. The company have had great difficulties to contend with in this level, in the shape of faults and wants in the coal, yet they persevered until they have got this level at the face over 1,500 yards in from the shaft, and under the water of the harbour nearly all the way. They have not yet got good coal in the face of the level, as they are trying to get through a fault; but the stalls, in a few yards after they leave the level, get over the fault and get into good coal, where the company have now got quite a large piece of it opened out, which proves to be very good and hard, varying in thickness from 6 to 10 feet, so that once the level, or main gangway, gets clear of the faults and into the good coal they will soon be able to make a large opening, which will greatly increase the output of coal.

"There is also a slope in this mine (mentioned in a former report). This slope is now down over 1,000 yards, going direct under the water of Nanaimo Harbour, with about 850 feet of rock, etc., intervening, so that little or no water comes from the roof, and what does come is free from salt. In this slope, as in the No. 1 Level, there is much ground which will not be profitable to work, and at present the coal is not very thick at the face of the slope. In this slope have been three levels on each side; those on the north side are known as No. 2, 3, and 4, north levels, and from those levels the company take a large amount of coal daily; although there are many bad places, yet when the coal is good it is generally very thick, and turns out well. On the south side the levels are known as No. 2, 3, and 4, south levels. About 50 yards down the slope to the south side there branches off what is called the Diagonal Slope at an angle from the Main Slope of fifty-four degrees; this slope intersects with No. 2 and 3 levels. The engine at the top of the slope takes away the coal from these places, causing a great saving of labour in not running the coal to the main slope. The coal down here is very thick sometimes; at one time they could not tell how thick it was, as they could neither see top nor bottom; this slope is being pushed ahead, so, also, is the No. 4 Level, which is near to the bottom of the main slope, and eventually this level will intersect the Diagonal Slope, when the engine at the top will also take away the coal in place of running it out to the main slope by men or mules. As you will have observed there is very much ground that is not workable, yet the company are now sending out over 800 tons of coal per day, with prospects of improving.

"Ventilation is good; the motive power has

been a furnace in connection with a steam jet, and the engine at the top of the slope exhausting into the No. 2, or upcast shaft. When I was down on the 23rd December there were 45,000 cubic feet of air in circulation per minute for the use of 118 men and boys; here the ventilation is on the separate split system, the main division being from the slope, taking the levels on either side as the intake returning by the way of the stalls, and as the pure air gets to the lowest place first, it is gradually on the ascend after it leaves the slope.

"There is now very little gas seen in this mine, but sometimes the firemen come across a little of it, and the appearance of a little reminds them of the necessity of being very careful.

"You will have noticed that I stated that the motive power of the ventilation has been a furnace and steam jet, but now it is a suction fan of the largest size. This fan has been erected about 100 feet from the upcast shaft, where an excavation has been made to the depth of about 18 feet, and continuing the excavation from the fan to the upcast shaft with a down grade going to the shaft. This part of the airway has been heavily timbered and planked, and covered over with fine ashes, so that everything may be closely sealed. This fan has been put up at a great expense to the company, but they could see that it was what their extensive mine required, and they have got a machine which, I expect, will ever do the requirements of this mine. The diameter of the fan is 36 feet, and its width 12 feet; it is worked by an engine of 26-inch cylinder with 30-inch stroke; the engine, and nearly all the machinery in connection with the ponderous machine, came from England, and it is a relief to the company, and also to the manager, to know that they have got appliances to keep in motion all the air that will be required to dilute all noxious gases that this extensive mine is likely to give off. This fan is now a running machine. I know this, but have not tested it. The manager, Mr. W. McGregor, has, however, tried its power on different occasions, while running quite slow, and he never found less than 60,000 cubic feet per minute.

"Everything about the mine is kept in good order, and no expense is spared to make it safe (as far as can be seen); there is always plenty of timber and every other material on hand that is necessary. It is to be hoped that this valuable mine, after all the expense the company have been put to, will yet be a financial success, which will be good for the company, people of Nanaimo, and the Province in general.

"It will be interesting for me to add that in this mine, at the bottom of the No. 2 or air shaft, the company have been prospecting by putting down a bore-hole with diamond drilling machinery. Here they have been very successful, for at a depth of 70 feet below the bottom of the shaft, or 700 feet from the surface they struck coal, which this bore-hole proves to be 6 feet thick, good and hard; and on testing some of the coal that was got out of the hole as to its gas making qualities, it was found that it was equal to the Douglas coal. This bore is being continued and is now down 100 feet, and there are yet very encouraging prospects of finding another seam of coal. I have good authority to say that when this hole is stopped, at no distant date thereafter the company will start to sink the shaft and push it with all haste down to the coal or coals that may yet be got at, and it is to be hoped when they get their shaft down that the coal will exceed their expectations, both as regards quality and regu-

*These totals represent the quantity of coal actually received in San Francisco, and other ports in California, during the years indicated, not necessarily the quantities shipped to those ports in the years named.

larity. This is a valuable discovery to the city, and a place where a great many will be employed; it will also be beneficial to every person about the town and in the Province generally. Last, though not least, it may be a reward to the Vancouver Coal Company, which has been so liberal in furnishing the means to search for and find such hidden treasures.

"SOUTH FIELD MINE.

"This is also one of the Vancouver Coal Company's mines. During the past year this mine has been about at a stand, except so far as the keeping out of the water; but that is no fault of the mine; the officers of the company found they could supply the demand from their other mine. The mine stands to-day almost as it stood a year ago, when the miners brought their tools out, and when the market revives, which I hope will be soon, the company will be well prepared, as they will be able to start work with two days' notice and have an output of coal the first day.

"WELLINGTON COLLIERY,

"Belonging to Messrs. Robert Dunsmuir & Sons. The Wellington mine is the original of the Wellington Colliery; this mine has been in operation for about 16 or 17 years, and now it is getting nearly worked out, not on account of the coal being done, but owing to other mines cutting off all round.

"This has been a valuable property, and is yet. During the year that is past the work has been principally at the pillars (of coal) and other coal along the outcrop; all the lower levels are now finished and they are now working at the pillars in the upper levels, which will continue to give a good supply of coal for quite a long time yet. The coal that is being got out is of the best quality of the Wellington coal and similar to what was got out 12 or 14 years ago, this being the coal they went through and left to support the workings behind them.

"Ventilation is good; motive power, a large furnace, with two air shafts or outlets; gas is seldom or never seen here, except on some occasions, as when a large 'cave' takes place. The fireman examines all the mine, by night as well as by day, to see if any of the caves let off any gas, and that none collects, and to report to the workmen whether or not the mine is in a safe condition for them to proceed to work. In connection with this mine there is what is known as the Adit level, that is a level going out into the valley of the Millstone River; the coal being taken out that way. Here there has been considerable idle time, as the coal trade has not been in a condition to work it steadily; but here, as in all the other mines belonging to Messrs. Dunsmuir & Sons, they only work when there is a demand and means of taking away the coal.

"Ventilation is good. This part is partly ventilated by the Wellington mine and partly by an air shaft with a furnace. At either of the above mines I always saw plenty of timber and other things necessary for general use about the mines.

"No. 3 Pit, WELLINGTON COLLIERY.

"This is the only shaft worked in the valley of the Millstone by Messrs. Robert Dunsmuir & Sons, with the exception of the air shaft. This mine is worked by a slope, with the top of it near the bottom of the shaft, with the levels from either side. Here the coal is worked on the pillar and stall system, and as the workings are under the valley they leave large pillars to support the roof. In this mine there is a long stretch of coal in sight, and as good as any coal

that has ever been opened out in the Wellington Colliery, from 7 to 11 feet thick, all hard and good.

"Ventilation is very good; when I was down in December there were 43,875 cubic feet per minute in circulation for the use of 70 men. This mine is also ventilated on the separate split system, and as the workings are from both sides of the slope the main divisions of the air are also from the slope to either side; on the one side going in the level and returning by the way of the faces or stalls, and on the other, going around the faces of stalls and coming out in the level, thence to the upcast shaft; the motive power here is a fan on the top of the upcast shaft. This being the first fan that was erected in this Province on a large scale for ventilating of our mines, which has done such good service and gives such good satisfaction, so that in this colliery there are three of them working. There is now little or no gas seen in this pit. Everything is kept in good order, with plenty of everything that may be required for the successful working of a mine.

"No. 4 Pit, WELLINGTON COLLIERY.

"This is the pit overlooking the valley of the Millstone. Mining in this pit is carried on very extensively; but here, as in all the other mines, there has been considerable idle time during the past year, and that owing to the depression in the coal trade. The coal is worked from this pit by what is known as the North and South side workings. The coal in this mine is very good, although they meet with a small fault occasionally, but not enough to hinder them much. Here in this pit they have a large area of good coal in sight, which will last for years to come. This mine is now connected with the shaft previously mentioned as the No. 6 pit, and which is now the No. 4 Air-shaft, and on this shaft there is a large ventilating fan. Ventilation is good, and is conducted on the separate split system, the main division being at the bottom of the shaft to each side, and other divisions further in the workings. When I tested the air, one of the last times I was in the mine, I found there was 75,500 cubic feet per minute for the use of 112 men. This was when all the divisions had again united in one, and going towards the upcast shaft. This mine continues to give off gas at times in different places; but it is seldom the fireman finds any, as it is carried away as given off. In connection with this mine, and on the top of the upcast shaft, there is a large ventilating fan, 30x10 feet wide, worked by a large steam engine; and here there is also a large steam jet in readiness at any time to turn on steam, in case of any accident to either fan or engine. At this mine I have never found less than 400 cubic feet per minute for each man or boy.

"No. 5 Pit, WELLINGTON COLLIERY.

"In this pit there has also been considerable idle time, for the same reason as that which caused the dullness in the other mines. At one time this mine did not look as well for getting out coal as may have been wished, but for some time back it has taken a change for the better. At present it looks well, and if the coal trade and prices would justify them to do so, they have places here standing idle, where they could employ 50 more miners than they are working at present. This mine is worked on the pillar and stall system, as are all the mines belonging to Messrs. R. Dunsmuir & Sons. The coal is of the usual good quality of the Wellington seam.

"Ventilation is very good. You will observe

in my previous report that they were sinking a shaft about 80 yards south of this, the No. 5 Pit. This shaft was got down early in the year, and connected with the workings here; and now that shaft is the upcast and return for the No. 5 Pit. Motive power here is a steam engine with a fan on the top of the upcast shaft, and the last time I was down there was 54,250 cubic feet of air per minute, for the use of 70 men and 3 mules. This mine is also ventilated on the separate split system, the main divisions at the bottom of the shaft taking the levels on the east and west sides, and returning by way of the faces to the upcast shaft. Here there is also a steam jet standing in readiness to turn on steam to ventilate the mine, if any accident should happen to either engine or fan. Here, as at all the other mines in colliery, there is always plenty of timber on hand, and every other thing which may be thought necessary to the use and working of a coal mine."

EAST WELLINGTON COLLIERY,

"The property of R. D. Chandler, Esq., San Francisco. There is only one mine in this colliery and that is in the valley of the Millstone River, and south-east of the Wellington Colliery. In this mine they have been very much troubled with wants and faults in the coal, and at the best the coal has been thin. The coal worked here is what is known as the Wellington coal. The mine has been worked steadily the most of the past year. Although not taking out much coal, yet what they do get is very hard and of good quality.

"You will have seen in my previous report that in the level going west they were in about 400 yards, and at the face they got a fault which put the coal 34 feet above the level. They went up over the fault, and continuing their level for nearly 300 yards on the upper side of the fault, with the coal varying from 5 to 6½ feet thick, good and hard, and improving as they go in. This is a good prospect, and to all appearances there will yet be a good and profitable mine here. The place where they have got the coal is a long way from the shaft, and it will be very expensive to make a good road up to get the coal down; but Mr. Wm. Chandler, the Manager, told me that if the coal keeps as good as at present, there is a likelihood of their putting down another shaft in the spring. The coal in the lower side of the fault is being worked on the long-wall system, and they are very successful with it, the coal averaging about 2½ feet thick. The refuse, and the rock taken out of the roof to make the roadway, fill the waste works full, so that the roof does not settle much, the roofing being a strong hard rock bending down gradually behind them as they work out the coal. As the roof does not break at the face, the workman hardly knows that it is settling.

"Ventilation is good; motive power, a furnace. The last time I was down, the air in circulation was 250 cubic feet per minute for each man employed. Owing to this being long-wall work, there is very little powder used, and in most of the places none at all. Sometimes the breaks in the roof, out a considerable distance from the face, give off a little gas, but at the face they never see any. There are not many men employed here, and as there is only one single shaft, they work what men they have on two shifts, sometimes three shifts a day. It is to be hoped that the coal will continue to keep good on the upper side of the fault previously mentioned, and also that it may get thicker on the lower side. Such improved prospects would be beneficial to all about the district, and the proprietor in particular. He

is deserving of such success, seeing the perseverance and push he has made here in bringing about the present position and prospects of the mine.

GENERAL.

All the above works I have frequently inspected during the past year, and I found them generally in good order, with plenty of timber and every other thing necessary on hand that was required, or may have been wanted for the carrying on and working of a mine. In the course of my inspection of the several mines, I sometimes have drawn the attention of the overman, or whoever happened to be with me at the time, to something I thought necessary to be done; and whatever it may have been, it was attended to at once. I nearly always found the brattice, as close to the face as it was convenient to have it, and it was no uncommon occurrence to get it broken down when blasting; and very often the miners complain on that account, as they do not like to break it. But in the places that are suspected of giving off gas they keep the brattice boards as close to the face as possible, if it should be broken down; and then for a few feet further they have a canvas or brattice cloth hanging from the roof, not being so much in the way as boards and serves the purpose of brattice equally well."

A Chemical View of the Metallic Minerals.*

C. F. Marsan, O.M.I., M.A.

Professor of Chemistry, University of Ottawa.

In the midst of the universal advancement of science, mineralogy is too useful and practical, not to have made immense progress during these late years. In fact every branch of it has received a new impulse. Petrography and the use of polarizing instruments has made crystallography available even in massive specimens, and in rocks of the most complex composition. Mineral chemistry, thanks particularly to the perseverance of German investigators, has discovered many new, accurate, and rapid methods of determining the constituents of minerals. Spectrum analysis has penetrated the recesses of rare elements, and found secrets so far left unrevealed. The list of species has received many curious additions, whilst in a more practical field all the mining industries have found in science most profitable suggestions.

Yet, surprising as it may seem, the elementary study of mineralogy has not benefitted by all this progress. The science, itself, has advanced, but the teaching of it has continued in the old paths, opened in the infancy of the science, and ever since trodden by routine. The result of this has been to discourage every effort for making the study of minerals more attractive and popular. If we except the analyst, who examines minerals as he would any other substance, and the practical min-

eralogist, who uses the blowpipe to verify the determination suggested mainly by the familiar appearance of the minerals. There are very few who pay any attention to mineralogy. You have not here, as in the other sciences, that multitude of young naturalists, who, though not conversant with all the scientific mysteries of their favorite branch, are, however, ardent and enthusiastic pursuers of the most accessible truths of Botany, Ornithology or Entomology. It is a well known fact also, that mineralogy has never yet received much consideration as a means of forming the intelligence of youth. Its place, when it had any, outside of exclusively scientific or technical programme of study, has been insignificant. Teachers have doubted its efficiency in training the mind, and students have either repulsed it as an unnecessary taxation of the memory, or adopted it only as a mechanical amusement.

In a lecture delivered before the Mineralogical Society of the College of Ottawa two years ago, and in a paper read before the Ottawa Field Naturalist's Club, in February, 1886, I advocated the introduction of a new system for the teaching of Mineralogy. Convinced that the failure of making this study both beneficial and attractive, was the outcome of certain defects, I suggested a method which to me seemed to avoid most of these defects and to introduce certain features which belong essentially to the science, though they had not been taken advantage of in the elementary study of the science. My first opening on this subject was rather a speculative venture, but ever since I have endeavoured to make a practical application of the method then outlined. The result of my experiment, with special reference to the study of metallic minerals, is the subject of this paper.

Practice must always be based upon principles. The first principle in the matter now before us is the absolute dependence of mineralogy upon chemistry. Mineralogy has no laws of its own, no principle; these it has borrowed from chemistry. This may at first seem strange, as chemistry belongs to physical science, whilst mineralogy is justly regarded as constituting a branch of natural history, as botany, zoology, &c. But there is a great difference between mineralogy, and its sister natural science. Whilst botany and zoology themselves depend upon chemistry for the laws which govern all matter, in whatever form it may exist, they take their special features and ultimate constitution from biology, the great science of life. For in the vegetable and animal kingdoms, the universal forms of inanimate matter, though governed by the same physical and chemical agencies, are absorbed by that mysterious power which is called life. Not so in the mineral kingdom. In the absence of life matter displays its own remarkable power, and the results coming from this single source follow with a mathematical accuracy. In the cabinet of the chemist, or in the secret laboratories of nature itself, the same agencies are ever at work, and the merely conventional distinction between artificial substances and minerals proper falls to the ground in presence of the production, by the chemist, of the very wonders of the mineral world. Chemistry is, therefore, the parent science of mineralogy. It supplies to the latter its principles, its laws, its very classification. And yet in one actual system the study of mineralogy has very little connection with chemical science. Though as a rule a course of chemistry precedes that of mineralogy, yet the student who ventures into the class of mineralogy, without any chemical knowledge, is scarcely less favoured than his

better prepared companions. Thus severed from its natural source, descriptive mineralogy is little more than a list of species more or less connected with each other, but never sufficiently to give a general view of the science, and to exhibit these great principles of chemical theory of which some mineral groups are the most striking illustration. You easily perceive how this separation detracts from the practical usefulness of mineralogy as a means of training the mind in general, and in particular raising it to the comprehension of the beautiful principles of natural science. But it has also another effect detrimental to the study itself. The separation of mineralogy from chemistry must necessarily entail the separation of determinative from descriptive mineralogy. For as soon as the determination of minerals is effected independently of chemistry, other characters are resorted to, and properties of minor order must serve almost alone to identify mineral species. A new system of classifying minerals has thus been created, a system as distinct from the logical classification as would be an entirely new science. One must of course use this system in the absence of any other; and practical mineralogists have at all times made use of it. But how could it be rationally introduced in a higher science or art? Would it not necessarily create confusion instead of light in the mind of the student? Must it not destroy all sentiment of order, all idea of logic, and induce men to believe that nature is a vast museum, where all specimens are labelled, but classified, and where the writer may begin at the end, or in fact at any part of the vast collection, and adopt whatever system his fancy may originate. Yet, with its imperfection determination plays an important part and cannot for usefulness and interest be replaced by any other mode of study, whether in this or any other branch of natural history.

The question, therefore, naturally arises: Is it possible to construct a system of teaching where everything will take its proper place, and where chemistry specially will be given the prominence due to it? Will that same system employ determination as the natural road to lead to the knowledge of minerals? Finally, will that system admit of being sufficiently elementary to agree with the manifold requirements of the programmes of our high schools and colleges, and yet sufficiently thorough not to deserve to be ranked with that superficial daubing of science which is next worse to complete ignorance?

I hope that the system which I want to propose may be itself a satisfactory answer to all these questions, and I proceed without any further preliminary to give the details of this new scheme.

(To be Continued).

Summary of Meetings.

Mineralogical Society of the College of Ottawa.

February 2nd.—The society held its semi-annual elections; the meeting being presided by the director, Rev. C. F. Marsan, O.M.I., M.A. The following officers were elected: President, M. Fallon, class of 1889, of Kingston, Ont.; Vice-President, J. P. Reynolds; Treasurer, E. Leonard; Recording Secretary, D. R. Macdonald; Scientific Secretary, Rev. Bro. Gauvreau, O.M.I.; Councillors, F. Mudget, T. Smith; Chemist, A. L. Tourchot, B.A.; Librarian, R. Paradis; Curator of the Museum, J. Paradis.

February 16.—Mr. D. R. Macdonald read a paper on "heat" as a geological agent.

*Paper read before the Field Naturalist Club, of Ottawa, March 3rd, 1887.

February 23rd.—An analysis of *Celestite*, by Rev. G. Gauvreau, elicited a certain proportion of Barium Sulphate, and some curious observations with respect to the crystallization.

March 2nd.—Mr. D. B. Thibaudeau read an instructive essay on the properties and manufacture of iron. A publishing committee was then appointed, composed of the following gentlemen: M. M. C. Kennedy, L. Dausereau, F. Mudget, E. Leonard, J. Paradis and C. Gaudet.

British Columbia.

Railroading Across the Rockies—Natural Obstacles, and How They are Overcome—A Brantford Firm's Contribution to the Work.

The Waterous Company, of Brantford, have received the following interesting letter:—

ROSS SAW MILL, Duggan's Siding, B. C.
C. H. Waterous, Jr., Waterous Eng. W. Co.
Brantford.

DEAR SIR,—As I have now finished here cutting with the mill, I thought that you would be pleased to know how it worked and what amount this mill is able to cut when run with proper care. As it is the first of this particular style of mill (25 h. power) you have sent to the Rockies, and as I have kept an account of all expenses of running this mill and the amount it cut, I am able to give you a correct statement of what it cost to handle lumber in this part. Any of your customers may rely upon the truth of my statements. As you are aware, I left Brantford on the 26th May, the mill being shipped at the same time. I arrived at the Rockies on the 8th of June, by way of the Canadian Pacific Railway. The mill arrived on the 12th and on the 21st we started to saw, and by the 8th of November we had cut 3,500,800 feet. The last month's cutting was the largest, amounting to 817,000 feet. These are the figures of the measurer employed by the C. P. R., and are correct, making an average of 31,423 feet per day of not more than 13 running hours per day. This was all cut into inch boards, and 3 and 4 inch planks, and all sized to 8, 10, 12 and 14 wide. All the cutting and edging had to be done with the large saw as we had no edger. The timber was spruce, pine, fir, cedar and hemlock. I see in some of your circulars that you give the amount of what has been cut per hour and per day, but I thought it would be more satisfactory to you and to your customers to know what such a mill could do in the season, and you may rely upon this statement as being absolutely correct during this time. The expenses for repairs only amounted to \$1.50, viz., for 1 bolt in friction lever, 1 bolt in saw lever, and repairs on timber gauge. This mill was never stopped one working hour during the whole season. The new pul-dogs are a complete success, they are quick and sure to hold every time. I am satisfied that there need be no trouble or delay in running these mills if they are properly looked after. There was no extra chance to make this mill run any better than any other. The men were all picked up as they came along. The only man that had any experience in a mill was the sawyer. I filed the saws myself and kept all other things right. It might be interesting for you to know how much timber it takes to build one of these snow-slide sheds per mile. It takes over 6,461,300 ft. of timber and 62,030 bolts 36 in. long, and 200,000 spikes 10 in. long. I do not refer above to the ordinary snow sheds such as used on the Intercolonial Railway, these are used here also where snow is likely to drift in, but in speaking above I refer to what might more properly be called snow slides. They are built at a point where snow-slides are apt to occur, always in the face of steep and high mountains. One side (the high side of shed) is built up into the side of the mountain and has a slant over the track something like a shed roof. They are wonderfully strong and you may be sure none too much so, as the accumulated snow of many years may start from the top of these lofty hills and come thundering down in masses 50 to 100 or 200 feet thick, with a force that nothing can resist unless it is the mountain on the other side of the valley from which the slide takes place. The snow in passing down slides over the top of the snow slide and passes on down into the valley and on up, may be several hundred feet up, the side of the mountain opposite. One can imagine what would be the result of such a slide striking a passing train. Certainly nothing but pieces of the smashed up wreck, that would be unrecognizable, would ever be found. Near where I am one of these slides happened. The snow came down the mountain in a body estimated to

be 175 feet thick. It struck the track and carried it bodily down the mountain to the valley across the river that flowed through the valley, and up the opposite side to about the same height. There was where the railway track was found after the snow melted. Some cars were wrecked at the same time, and were never found, probably the remains were carried down by the melting snow to the Columbia River, and then out to the Pacific Ocean. The location here is a very beautiful one. A photographer who is out among the mountains taking views for the Canadian Pacific, came along one day and took a picture of the mill, and I send you one which will give you a very fair idea of what the place looks like. The mountain that you see to the left is over 5,000 feet high from the railway track. The white spot between the higher and lower peak is snow, and lies in that hollow place all the year round, and that snow is supposed to be 250 feet deep, and is a glacier, it is full of numerous cracks. The men have dropped lines down some of these cracks for over 100 feet without reaching the bottom. The sharp high peak seen on the picture is rough and jagged and difficult to climb. There was a rain cloud floated up against this peak once and burst, letting out a flood of water that brought everything down the mountain with it. Enormous rocks and trees were apparently no obstruction whatever. The course of the water made a clear sweep, and its peak is easily seen yet. As it came down the rocks and trees that it bore up would sometimes lodge in narrow places on the sides of the mountain and be piled up 150 or 200 feet high, but the weight of water behind would soon be so great that the dam would give way, and down would come the water again, and rocks, trees, etc., and so it kept on until it reached the river, which was raised by this flood until the water stood 20 feet over the track. This cloud burst did a great deal toward preparing the mill site. Level places, large enough to build a mill on are hard to get up here in the mountains. There are some very interesting things up here, and one need not get very lonesome if he has any taste for curious nature. A little way from the mill are soda springs and hot springs, so you can have both a plain soda and a hot bath, one or both, as you choose, and no thanks to any one. Soda plain, however. No liquor is allowed up here, which is a good thing, where so many and such different kinds of men are employed away from law and order.

I have been up the Roumanian, Bulgarian and Thuringian mountains, but the mountains here, I think, are much grander. It is not possible to picture them. However, as you have been on the Andes and Alps, you can think back a few years to the time we were in Santiago, Chili (I now see by the papers you are the Hon. Vice-Consul of that progressive republic), and used together take a walk to the top of Santa Lucia and look off to the snow-capped Andes it will give you an idea of this place. Only I am here in the very midst of them; then we were at a distance. Should you or any of the Brantford people be taking a trip over the Canada Pacific to British Columbia they can remember when going through these sheds that Brantford saw mills with Brantford brains and muscle cut the six million or more feet of lumber that is required to build each mill. For this is not the only one of your mills here; there are a number of them, and I can tell you it does me good to know that no other mill, American or Canadian (and there are a good many, especially of the former, scattered around the mountains), have done as much or as good work as our own mills. I naturally feel a pride in the old shop and what it does. I have been with you now some 30 years, and there are there still at work men who commenced before I did, and I want you to let them know what this mill has done up here, for I know they will be glad to hear from it, and that their work is a success. As I am writing, my mind turns back to a time when we were having one of our annual shop picnics about the time the Canada Pacific was first being talked about. Mr. Robertson, of the Bank of British North America, was making a few remarks and spoke about the great railway, and said that it was sure to be built, and would carry from ocean to ocean the Brantford saw-mills. We have seen that now all come to pass, and that his forecast of the future was correct. I have seen the Brantford saw-mills go ahead and cut the timber to build the railway bed, the stations, and the fences, and now we have turned back and are cutting the timber and plank to cover the road where it is necessary to protect it from the snow. I have made this letter too long, but there is so much here to be seen and to write about that when you start to write you do not know when to stop. But I knew you take an interest in such things as are to be seen here. And I would say come along and see for yourself, and I am sure you will be well satisfied and paid for your trip. With no more at present,

I am your old fellow-traveller,

JOHN LYLE.

WM. HAMILTON MERRITT, F.G.S.

Associate Royal School of Mines, &c.,

Mining Engineer and Metallurgist,

Will report on Mines and Mineral Properties.

ADDRESS:

15 TORONTO ST., TORONTO, ONT.

FOR SALE.

LOT NO. 17, RANGE 7,
TOWNSHIP OF PORTLAND EAST,
COUNTY OF OTTAWA.

Continuation of the North Star Vein. Partly developed and showing very high indications.

For particulars apply to

PHOSPHATE PROPERTY In the Township of Portland West FOR SALE.

Lots 25, 26, 27 and 29 in the 3rd range. Some excellent surface shows have been uncovered on these lots and only require capital for developing. Price and particulars given at the office of the MINING REVIEW.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands, 1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place shall not exceed forty acres in area. Its length shall not be more than three times its breadth and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person who has discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as afore-said; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should a person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:— "Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR.

NOTICE.

SEALED TENDERS, addressed to the undersigned, and endorsed "Tender for Indian Supplies," will be received at this office up to noon of **SATURDAY**, 30th April, 1887, for the delivery of Indian Supplies during the fiscal year ending 30th June, 1888, consisting of Flour, Bacon, Groceries, Ammunition, Twine, Oxen, Cows, Bulls, Agricultural Implements, Tools, &c., duty paid, at various points in Manitoba and the North-West Territories.

Forms of tender containing full particulars relative to the Supplies required, dates of delivery, &c., may be had by applying to the undersigned, or to the Indian Commissioner at Regina, or to the Indian Office, Winnipeg.

Parties may tender for each description of goods (or for any portion of each description of goods) separately or for all the goods called for in the Schedules, and the Department reserves to itself the right to reject the whole or any part of a tender.

Each tender must be accompanied by an accepted Cheque on a Canadian Bank in favour of the Superintendent General of Indian Affairs for at least five per cent. of the amount of the tender which will be forfeited if the party tendering declines to enter into a contract based on such tender when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted, the cheque will be returned.

Tenderers must make up in the Money columns in the Schedule the total money value of the goods they offer to supply, or their tender will not be entertained.

Each tender must, in addition to the signature of the tenderer, be signed by two sureties acceptable to the Department, for the proper performance of the contract.

When implements of a particular make are mentioned it is because the articles so designated suit the Department for the purpose required better than others; in such cases the competition between tenderers must, of course, be in the transportation to the place of delivery.

In all cases where transportation may be only partial by rail, contractors must make proper arrangements for supplies to be forwarded at once from railway stations to their destination in the Government Warehouse at the point of delivery.

Tenderers will please note carefully the following conditions—

1. Supplies will not be paid for until the Department has been assured of the satisfactory delivery of each article for which payment is claimed.
2. No tender for supplies of a description different to that given in the index will be considered, and supplies which are found, on delivery, to be of a kind or quality different to those described, will be rejected by the agents of the Department; and the contractor and his sureties will be held responsible for any loss entailed on the Department through failure to deliver in accordance with terms of contract.
3. It must be distinctly understood that supplies are to be delivered at the various points for the prices named in the tender; that no additional charge for packing or any other account will be entertained, and that an invoice must accompany each separate delivery of supplies. An invoice for each separate delivery must also be sent to the Department of Indian Affairs at Ottawa, and one to the Indian Commissioner at Regina, if the supplies are for the North-West Territories. When the supplies are for points in the Manitoba Superintendency the triplicate invoice should be sent to E. McColl, Winnipeg.
4. Prices must be given for articles to be delivered at each point of delivery named in the Schedule for each article for which a tender is submitted, and not an average price for each article at all points of delivery; no tender based on a system of averages will be considered.
5. Tenderers should understand that they must bear the cost, not only of sending their samples to the Departments of Indian Affairs but also freight charges incurred in returning such samples to the tenderer.
6. When supplies are to be delivered "equal to sample," tenderers should understand that the sample is to be seen either at the Department of Indian Affairs, at the office of the Indian Commissioner at Regina, at the office of the Inspector in charge at Winnipeg, or at any one of the undermentioned Indian Agencies.

Department of Inland Revenue.

An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

TENDERS.

SEALED TENDERS, marked "For Mounted Police Provisions and Light Supplies," and addressed to the Honorable the President of the Privy Council, Ottawa, will be received up to noon on Monday, May 30th, 1887.

Printed forms of tenders, containing full information as to the articles and approximate quantities required, may be had on application at any of the Mounted Police Posts in the North-West, or at the office of the undersigned.

No tender will be received unless made on such printed forms.

The lowest or any tender not necessarily accepted.

Each tender must be accompanied by an accepted Canadian bank cheque for an amount equal to ten per cent. of the total value of the articles tendered for, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the service contracted for. If the tender be not accepted the cheque will be returned.

No payment will be made to newspapers inserting this advertisement without authority having been first obtained.

FRED. WHITE,
Comptroller, N. W. M. Police.
Ottawa, March 25th, 1887.

The engraving represents the **Hartsfeld Transportable Water Jacketed Smelting Furnace, Metal Dust Condenser and a Separator Crucible**, manufactured by the

HARTSFELD

Portable Smelting Furnace and Mining Co.,

NEWPORT, KENTUCKY, U.S.A.,

In sizes from 5 to 60 ton capacity, and by the following licensed manufacturers on Royalty.

IMRAY & CO., London, Eng., and Melbourne, Australia.

F. A. HUNTINGTON & CO., Chihuahua, Mexico.

PARKE, LACY & CO., Auckland and Chili, S.A.

W. T. GARRETT & CO., San Francisco, Cal., for the Pacific Coast.

McILVAIN & SPIEGEL, Cincinnati, Ohio.

Letters Patent have been secured in all principal foreign countries, and are sold in shares, trade, royalty or otherwise. Run your eye over this and return answer: silence means no! Catalogue free.

This furnace requires no more care or attention than an ordinary steam boiler, and can be run as long and with as little loss of time or expense for repairs. Full information will be furnished by the

Hartsfeld Portable Smelting Furnace & Mining Co.

P.O. BOX 115 NEWPORT, Ky., U.S. of A.

Reduction Works, No. 90 and 92 Thornton St.

SEALED TENDERS, marked "For Mounted Police Clothing Supplies," and addressed to the Honorable the President of the Privy Council, Ottawa, will be received up to noon on Monday, 2nd May, 1887.

Printed forms of tender, containing full information as to the articles and quantities required, may be had on application to the undersigned.

No tenders will be received unless made on such printed forms. Patterns of all articles may be seen at the office of the undersigned.

Each tender must be accompanied by an accepted Canadian bank cheque for an amount equal to 10 per cent. of the total value of the articles tendered for, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender be not accepted the cheque will be returned.

No payment will be made to newspapers inserting this advertisement without authority having been first obtained.

Canadian Mining Review,

OTTAWA.

PUBLISHED MONTHLY.

ANNUAL SUBSCRIPTION \$1.00

ADVERTISING RATES . . . 15c. per line (12 lines to 1 inch).

OFFICE:

UNION CHAMBERS, 14 Metcalfe St.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 17th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Advertising Space.

The circulation of the CANADIAN MINING REVIEW, which has steadily been going up since its first publication, more than five years ago, has now more than doubled the estimate upon which we had reckoned, and its value as an advertising medium to business men who wish to reach the best classes of mine owners and operators, and the mining centres and camps of every province in the Dominion, is consequently very greatly enhanced. The REVIEW is in the widest sense a Canadian journal belonging to all provinces alike; it is the only journal published in Canada wholly devoted to the interests of her mining industries and mineral resources. We would simply draw the attention of those who have hitherto overlooked it, to this matter, promising our best attention and most reasonable terms on any application for advertising space.

A National Museum.

That there is a necessity for a National Museum has long been conceded, and the consensus of public opinion points to the present as a fitting season to press upon the Dominion Government the urgency of its speedy erection. It might be worth while to view the matter both from an economic and scientific standpoint. We place the former first, as, to the great mass of the people, this is of the first importance, the scientific aspect being chiefly for the few, although absolutely necessary as a basis for the proper working of the institution. Many suggestions have been made regarding the scope of the proposed institution, and many places have been named as suitable for its site at Ottawa, but it is not our intention to enter into these points other than to say that such a National Museum should be an extension of the

present Government Geological and Natural History Survey Museum at Ottawa, and should be kept strictly within the lines of that excellent Department. According to Act of Parliament this Survey now includes within the range of its operations the three kingdoms of nature as represented in our Dominion, and necessarily the new National Museum must include all these branches of its work. Keeping in view the objects of the Government when the Act was passed, Dr. Selwyn, the Director of the Survey, has steadily kept this in view in the arrangement of the present Government building, and although the space is very much cramped, both the economic and the scientific aspects have been carefully kept in view. Visitors to the museum can see a double arrangement of the mineral sections showing an economic and a scientific aspect, and the same arrangement in the animal, vegetable and other sections would have been carried out had space permitted. At the recent Indian and Colonial Exhibition our exhibitors were able to show the economic value of our resources by their wonderful collections of food fishes, large mammals and birds suitable for food. There too were shown the products of our mines, of our forests, and of our fields. Here in our own Capital we cannot show even to our members of Parliament the wealth of our country, and many of them are as ignorant of our great national resources as the veriest stranger who comes within our gates.

We do not want a building to cover acres of ground and cost millions of money, but we do want one large enough to exhibit the whole natural products of the country, and on such a scale as will make it possible to bring together from every portion of our great Dominion, as well as from foreign countries, such a collection as would be of great practical benefit to all Canadians engaged in industrial and scientific pursuits. To do this properly would require at least a building of three stories. The ground floor for minerals; the middle for fossils, and the top flat for botany and zoology. On this plan the heavy exhibits would be placed at the base and the lighter at the top. With the exception of offices, a building one-third larger than the present museum would be amply sufficient for many years.

Many reasons might be adduced in favor of the project but we only advance a few. The principal one is the insecurity of the present building. It may be destroyed by fire at any time. At present it holds the most precious collection of minerals, fossils, and botanical specimens contained in any one building on the American continent. The loss of such a valuable collection would be irreparable.—In a monetary sense they represent more than a million of dollars. They include much of the life work of Sir William Logan, Billings, Whiteaves, and Macoun, besides the gatherings of over forty years of the various other members of the staff. Surely these are worthy of a better fate.

Throughout the world to-day the cry is arising give us food for the mind as well as for the body, and the answer has been given almost everywhere, except Canada, by the erection and equipment of national museums for the enlightenment of the people. New South Wales, with a population less than that of Ontario, gave £15,000 last year to its museum in Melbourne. In the United States the practical aspect of the case has taken hold of the people, and in every State economic and scientific museums are being established, and specialists appointed to arrange and keep them in order. While the new Departmental and other public buildings, of which any nation might feel proud, were in course of construction, it was hardly proper to press this matter upon the government, but now that these are nearing completion it is both right and proper that the facts should be placed before the representatives of the people, and that they should be asked to assist the government, by their support, in projecting a scheme that will place Canada abreast of the other nations of the civilized world in the march of improvement.

The Yukon Expedition.

In a few days Dr. Dawson, Assistant Director of the Geological and Natural History Survey, accompanied by a small party, will start out on his expedition to the Yukon country. There he is to personally conduct the work relating to the Geological and Natural History of the country, and also to supervise that section of the exploration necessary to the topographical work. Mr. William Ogilvy, D.L.S., and astronomer, Ottawa, is to take charge of the topographical work, and will make an accurate survey and measurement of as much of the Yukon as lies within British territory. It is thought that Mr. Ogilvy will remain in the district during the whole of the winter of 1887, but Dr. Dawson is to return next fall by the Chilkoot Yukon route, which will enable him to obtain accurate geological data of the whole route to be traversed by the expedition. It is likely that the portion of the expedition under Dr. Dawson's charge will be able to make an exploratory and track survey, with astronomical determination of points on the Stickeen River, and the remainder of the route, until he joins Mr. Ogilvy, which will materially add to the geographical and geological knowledge of the whole region. The expedition will leave Victoria, British Columbia, early in May, and it is calculated that Mr. Ogilvy will reach the summit of the Perrier Pass about the 1st of June, and that after a junction has been effected there he will have a clear month within which to explore the surrounding country and yet enable Dr. Dawson to get out in the fall before the rivers are frozen. A great deal has been said and written about the mineral resources of this section of that great northern land, and it has been

announced that gold exists there in abundance. During the past summer we are informed that on a bar of the Stewart river as high as \$150 per day to the hand was made for 28 consecutive days. On the Salmon River from \$25 to \$50 per day was taken out, and many other districts are mentioned where the efforts of the miner have met with more than average success. These are cited to prove that a great mining future is in store for that section of the North-West that is drained by the waters of the mighty Yukon. Some again do not speak so favourably of it. They say that the mining which is almost entirely Placer has been very largely exaggerated, and that many after undergoing extreme hardship and privation have been glad to get out of the country alive. Provisions, and food of any kind are so scarce and difficult to obtain that those adventurous spirits who have penetrated within the lines of that great lone land have but barely existed. In the absence of any information that is absolutely trustworthy, a great rush to the country at present is to be avoided. Such would only result in disaster to the parties themselves and to the industry which they would seek to cultivate. Dr. Dawson's expedition will do much to reveal the true state of affairs. From a practical as well as a scientific standpoint the expedition is of the utmost importance to the country.

Our Geological Survey.

The Federal Government of the United States appropriated in 1884, for this branch of the State surveys, the sum of \$339,640, being an increase on the amount voted in former years. The following Local or State Governments set apart for their local Geological Survey, or in the interests of the mining development in these states, the following sums: California, \$15,000 a year for State Mining Bureau; Indiana, \$5,000 a year; New York, \$16,000. The following states have in former years made similar appropriations for this purpose, and are now in receipt of the benefits to be received from so safe an investment of the public funds as the sure result of the most complete knowledge of the mineral resources within the State, viz: Ohio, Wisconsin, Michigan, Minnesota, Iowa, Illinois, Tennessee.

The latest Report on the Mineral Resources of the United States by Albert Williams, Jr., for the year 1882, gives the total mineral production during that year for all the States at \$453,912,406. In round numbers the large sum of four hundred and fifty-four millions of dollars, it having increased from 1882 till this time.

The total mineral production of Canada cannot be ascertained from the census of 1880-81 as the number of tons of each class of product only is given, and value per ton is not mentioned, and hence the necessity that this matter should receive attention when the proposed Labor Bureau is organized.

The Dominion of Canada expends annually about \$100,000 for Geological Survey purposes, including Natural History, but this must not be understood to be for exploration of Dominion Land alone, as the larger proportion or almost all of the sum is annually expended in the interests of the respective Provinces. This small appropriation is devoted to the Geological investigation of an extent of country covering an area of 3,500,000 square miles, and is territorially about equal in extent to the continent of Europe and larger in area than the United States and territories, but exclusive of Alaska. The Provincial or Local Governments at present do no Geological work, but in Newfoundland, which is not yet a Province of the Dominion, the sum of several thousand dollars has been of late years expended, and the minerals are retained by the Government for lease.

The Scientific and Educational uses of Geological work are of the highest importance, dealing with questions such as the origin of rocks and minerals, the changes that have taken place in the crust of the earth and are now taking place, these are the processes of formation and disintegration and result in the building up or destruction of continents, and many other subjects of interest not only to men of science but to the human race:—the true order and condition of things as they were and are now, reduced as Professor Huxley expresses it "to one long chain in the ceaseless causation of nature." The economic uses, however, interest us most and may be divided into four parts for purposes of illustration. The first necessity for the Geologist is a correct map or plan of the country to be examined; and this Dominion, as we have seen, is a rather large country and only partly surveyed, in which case the geologist has to first survey and map out the region. Certain rocks are found in the locality under examination and the question arises as to their age or period of formation, that is, do they contain evidences of animal or plant life? The Paleontologist is the judge in this case, and according to the evidence produced is the verdict. It is, therefore, seen that the study of Paleontology is of the first and highest importance to arrive at the correct stratigraphical and economic value of the rocks discovered and of the district under examination. In the event of no organic remains being discovered, and for the determination of such minerals and ores as may occur, their chemical composition has to be ascertained. This is the duty of the Mineralogist or Chemist. Ores having been found the question arises: are they of commercial value and in quantity to warrant the district being classed as a mining location? The settlement of this question is the province of the mining engineer, whose duty ought to be, under proper mining regulations or laws, the examination and inspection of the region, with the end in view to the full development of the minerals it contains. The notes taken in the field being disjointed or un-

connected as it were, have to be put in form so as to make an intelligible continuous readable account of the physical features, strata, &c., of the district. The work already mentioned is printed and published, and so to speak, tells its own story, but the geologist has of necessity a value to the public which does not show in print; it is that of giving information or explanation in writing, or by interview, of the district so reported on as a natural outcome of that publicity, and is often not by any means the least important duty to perform, and one that occupies much time and for which due credit ought to be given.

The map or plan can serve the double purpose of recording strata and indicating the occurrence of such minerals or ores as are of economic importance or scientific interest, including building materials, fertilizers, ores, coal, gas, oil, and mineral products used in the arts and manufactures. It can thus be clearly seen how great is the importance of geological work to the prosperity and happiness of the inhabitants of any country.

The advanced condition of Canadian geology will bear comparison with that of other countries and is highly creditable to so young a country and one of so extensive an area, but the great progress made in the early years was wholly due to the philanthropic spirit and a devotion to the science carried on at much personal expenditure and labor by the late Sir Wm. E. Logan, in whose praise it is not possible to pay too high a tribute. Since Confederation the Dominion has undertaken the work for the several provinces, and it is to be regretted that economically and financially the Provinces of New Brunswick, Quebec and Ontario have not made the best use of the mineral resources of these provinces, while Nova Scotia and British Columbia have retained the minerals and are now and will continue to receive benefits and income for so sure a course.

The large extent of territory only suitable for mining under Dominion and Provincial Governments makes it obligatory on these Governments that the best laws be enacted to encourage pioneer or individual exploration or prospecting with the view of the full development of the mineral wealth, and to receive in return a revenue to compensate for geological survey which is the certain and permanent result of such work.

In the Australian colonies where this industry is not neglected as it is in Canada, a minister of mines is the representative of the important industry of mining when the laws are such as to develop to the best advantage this source of national wealth of which we have a sufficiency in Canada for home and exportation use.

Mayor Stewart and Mr. W. A. Allan of Ottawa have received the bronze medal of the Indian and Colonial Exhibition for exhibits of coal and phosphate and other minerals sent by them.

The Cost of a Strike.

There is considerable monotony in repeating, time after time the story of what a great strike costs those who engage in it; but the lesson is sufficiently valuable to warrant infinite repetition in hope of ultimate conviction. Here is the latest tale of the kind:—

It is calculated that the total losses in wages by the recent strikes among the "Longshoremen" and other working people in New York and New Jersey, from January 1 to February 10, are 2,650,000 dollars, while the estimated loss of pay by 38,000 employees thrown out of work through scarcity of coal, or cognate cause, is 350,000 dollars. In addition to these figures we have:—Total extra amount paid for coal through strikes, 700,000 dollars; total losses incurred by steamship companies through delay, 100,000 dollars; total losses to coal-shippers, 100,000; total estimated losses of the export trade of New York in two weeks, 3,380,000 dollars. Persons interested in promoting strikes nearer home than New York or New Jersey might profitably employ some of their leisure in calculating how much, if any, profit has accrued by way of counterpoise to these figures.

We have received the second volume of the Journal of the Iron and Steel Institute of London, England, for 1886. This valuable and ever welcome work is edited by Mr. J. S. Jeans, and is largely made up of the transactions of the Institute at the last meeting held at London in October last. It contains verbatim reports of the many valuable papers read before the society then. These were "The Erosion of Gun-Barrels by Powder Products," by Sir F. Abel, C.B., F.R.S., and Col. Maitland; "The Iron-making Resources of the Colonies, as illustrated by the Colonial and Indian Exhibition," by Mr. P. C. Gilchrist and Mr. Edward Riley; "Some early forms of Bessemer Converters," by Sir Henry Bessemer, F.R.S.; "Modifications of Bessemer Converters for small charges," by Mr. John Hardisty; "On Combustion with Special Reference to Practical Requirements," by Mr. Frederick Siemens; "The Removal of the Metalloids in the Basic Open-Hearth Process," by Mr. F. W. Harbord; "The Casting of Chains in Solid Steel," by M. F. Gautier; "The Process employed in casting brass chains in Jeypore, Rajputana," by Surgeon-Major T. H. Hendley and Mr. C. H. Purdon Clarke, C.E.; "On Silicon in Foundry Iron," by M. F. Gautier; "The Chemical composition and mechanical properties of Chrome Steel," by M. Brustlein; "American Blast Furnace Practice with special reference to the works of the North Chicago Rolling Mill Company," by Mr. F. W. Gordon. One of the most attractive features of the volume is the very carefully compiled "Notes on the Progress of the Home and Foreign Iron and Steel Industries" classified under the heads of iron ores, fuel, refractory materials, production of

pig iron, production of malleable iron, forge and mill machinery, production of steel, &c., &c. In these a vast amount of useful information is included. Altogether the publication is of great worth and interest.

Iron, Steel and Coal in Canada.

The development of the coal and iron industries of the Dominion of Canada is at the present time a duty imperative upon the Dominion Government. Since Confederation the Dominion has incurred a large national debt abroad on which interest only has been paid, and the burden has therefore been light upon the people. Otherwise, the country would never have been able to bear the strain imposed by the excess in value of imports over exports, which, to July 1st, 1884, amounted to \$342,036,663.

To meet this excess of expenditure abroad Canada had only the annual revenue from her mercantile shipping, and the balance is represented by the national debt held abroad and a portion of the foreign capital invested in this country. The greater part of this excess of imports over exports is also represented by the importations into Canada of iron and steel to the value of \$230,741,434 since 1867. It thus becomes apparent that if Canada is to prevent the possibility of commercial bankruptcy, she must produce at home the iron and steel which has hitherto been imported from abroad for home consumption. It was wise and prudent to increase the national debt by constructing vast and necessary public works throughout the Dominion, at a comparatively small annual interest charged to the people; but as soon as Canada would attempt to live within herself and make her annual exports pay for her imports, then must she undertake to produce her iron and steel at home, rather than depend upon foreign nations for her annual consumption. The best way to do this is the problem, to the solution of which the statesmen of Canada must at once address themselves.

We use the statistics for 1884, as we have them compiled to hand. In that year Canada had about 10,000 miles of railway in operation; or an investment in railroads of \$.04 per head of the inhabitants which was only exceeded by that of Great Britain averaging \$107 per head, and that of the United States averaging \$112 per head; and at the same time it must be remembered that there is no other country in the world, which has such investments in railroads as those of Canada, that does not manufacture its own rails; while on the other hand there is no country in the world which has in its possession such natural advantages for the manufacture of iron and steel as those of this same Dominion. Yet what do we find? Instead of manufacturing our rails, we have imported in one year rails to the value of \$5,891,861, and in the same year iron to the value of \$9,456,189, which, together with the imports of iron and steel manufactures, aggregated an importation for Canadian consumption in one year of \$26,791,152. The question for Canadians to answer is how long can Canada afford to do this, with iron, coal, limestone, etc. offering unsurpassed advantages for the production of iron and steel, and the manufactures thereof, lying useless and worthless at her feet. At the same time, we have not only lost a home market for the coal which would have been consumed in the production of this iron and steel, but we have imported from abroad nearly \$60,000,000 of coal and coke for home

consumption. Certainly these facts are startling indeed.

The average annual excess of imports over exports into Canada to 1867-83, was \$20,119,804; the average importation of iron and steel and the manufactures thereof was \$13,573,600. In order to compare this showing with that of the United States, we produce the following per capita statistics:—

CONSUMPTION PER CAPITA OF IRON AND STEEL IMPORTATIONS.		
Year.	Canada. cents.	United States. cents.
1867.....	—	69.03
1868.....	204.47	61.21
1869.....	216.78	74.37
1870.....	224.89	84.26
1871.....	301.00	109.35
1872.....	454.85	130.26
1873.....	701.41	137.47
1874.....	577.16	80.99
1875.....	515.33	46.47
1876.....	345.76	28.40
1877.....	289.38	21.92
1878.....	240.38	17.77
1879.....	199.57	19.62
1880.....	248.88	90.66
1881.....	297.69	99.99
1882.....	404.63	102.27
1883.....	455.80	74.40
1884.....	332.26	—

It will thus appear that while Canada has been importing iron and steel to the amount of \$7.01 per head in one year, the highest importation into the United States has only been \$1.37 per head. It is equally noteworthy that in Canada in the one year, the average rate of duty on the dutiable importation was 11.05 per cent; while in the United States in the other year the average rate on the dutiable importation was 31.81 per cent. The highest rate of duty levied in Canada in those seventeen years was 21.08 p.c., the lowest was 10.98 p.c. In the United States, the highest was 49.21 p.c.; the lowest was 31.46 p.c. These facts are suggestive as indicating that the United States have protected the home producers by tariffs ranging from 31 p.c. to 49 p.c., and have thereby encouraged home production and decreased the foreign importations. Canada has simply levied a revenue tariff ranging from 11 p.c. to 21 p.c. which has failed to encourage home production, while the country has sent \$230,741,434 (1867-83) out of the country to purchase these iron and steel products abroad.

No country in the world has developed its iron interests except by a policy of protection. England, United States, Germany, France, Russia, Sweden have all fostered this industry by special legislation. Canada has thus far done but little toward this end. About 20,000,000 tons of pig iron and 6,000,000 tons of steel are now annually produced, together with 400,000,000 tons of coal. With unsurpassed facilities for their production should Canada remain careless and indifferent?

From 1867 till 1880 pig iron was on the free list in Canada. What wonder that its production was not successfully attempted?

In 1880, a specific duty of \$2.00 per ton was levied; and from July 1st, 1883, to July 1st, 1886, a bounty of \$1.50 per ton was granted.

In the latter year the bounty was reduced to \$1.00.

The United States levy a duty of \$10.00 per ton on pig iron; and \$12.50 per ton on scrap iron. These are fair samples of the different policies of the two countries. Shall Canada continue to give a duty and a bounty, combined,

of \$3.00, or shall the duties be removed from raw sugars and other raw imports, and from \$10.00 to \$15.00 be levied on pig and scrap iron, for instance, in order to foster the iron industries at home?

PHOSPHATE.

Latest English Quotations.

MINERAL PHOSPHATES.—The business done in Canadian has been principally on Continental account, and this has been restricted by a demand on the part of the Raisers for an increased price, and also by their unwillingness to sell until their prospects of output are more assured. Last season the quantity was several thousand tons less than the previous year, and Raisers are now endeavouring not only to recover their shortage, but to swell the shipments during the approaching season. There is some enquiry for Ground Canadian, but as the American Buyers can pay a higher price for this article, there will probably be less shipped to this Market. South Carolina Phosphates are unchanged. The new French Phosphate increases in popularity, and must henceforth be considered as an element in the trade. Shippers are getting over their difficulties, and are now able to deliver with greater rapidity. Belgian Phosphate has been quiet since our last, Manufacturers mostly being stocked for their immediate requirements. The present appears to be a good time to secure next season's supplies. Latest price for Canadian eleven pence three farthings for 80 p.c. Cambridge and Bedford Coprolites are unchanged, and quoted at 43s. f.o.r., or Ground at 50s. in Buyer's bags, or 52s. in lent bags, f.o.r., the latter at 26s., f.o.r., or 31s. 6d., f.o.b., Thames.

The first Annual meeting of the shareholders of the Templeton and Blanche River Phosphate Mining Company (limited) was held at Montreal on the 31st ultimo. The following directors were elected:—President, Mr. Wm. Cassils; Vice-President, Mr. Honore Beaupre, ex-Mayor of Montreal; Sec.-Treasurer, Mr. Philip S. Ross.

Recent reports from the Buckingham district would seem to indicate that phosphate mining is moving northwards. Several hundreds of tons having lately been taken out of a mine on River du Suer, a tributary of the Du Lievre River, some forty miles above Buckingham. The mineral is said to be of excellent quality. It is hauled at present to the foot of the Long Rapids by sleighs, and as soon as the ice breaks up will be conveyed from that point to the village by scows.

Messrs. Poupere & Co., contractors, have completed their arrangements for the construction of the new stone lock and dam some 12 miles above Buckingham. The present advanced state of the phosphate industry has made the construction of these works an absolute necessity. The increased facilities for moving the ore now to be provided will reduce the cost of its transportation, and will enable miners to sell the ore at a lower figure than heretofore.

It is estimated that the output from the various mines in the Buckingham district for the season ending 1st May will be as follows: High Rock Mines about 6,000 tons; Union, about 5,000; North Star, 3,500; Little Rapids, 1,200; Emerald, 5,000; Anglo-Canadian, 1,000; Glasgow Phosphate Company, 500; McLaurin & Blackburn, 1,000; sundry smaller properties

about 300 tons. In all, it is thought, close in the vicinity of 25,000 tons will be mined. Of this quantity three-fourths will be high grade ore, averaging from 75% to 85%.

In view of the immediate opening of navigation, work on the various properties is being pushed vigorously forward. Additional hands are being employed, and new machinery operated by steam power is being largely adopted in preference to the old *modus operandi*.

Notwithstanding its very steep grade the tram line constructed on the High Rock property last season has proved most satisfactory, and at Little Rapids, the one now in course of construction, will be completed and in running order by the first week in June. We understand that the North Star and Emerald mines will shortly follow suit in the same direction.

The output from the High Rock mine for the month of March was the largest ever mined from any one phosphate property in the Dominion, and was as follows:—829 tons first quality, or all over 80%, and 39 tons of second quality which will yield over 70%. This was with an average of 135 men. This most gratifying result is in very large measure due to the superior mining plant at present in operation at this property. Nothing is done by hand that can be done by machinery, every particle of which is first-class.

The output from the Emerald mine for the same month figures close upon 500 tons with an average of 60 men.

It is understood that Mr. S. P. Franchot, the popular manager of the Ottawa Phosphate Mining Company, has recently acquired a half interest in 4 lots, formerly owned by Captain McNaughton at the High Falls, in the 10th Range of Portland, and that it is his intention to commence work early in the spring.

The shaft at the North Star is now down some 500 feet, and the management report a good show at the bottom. The output from this property and from the Union mine for the past month will be fully up to their ordinary monthly output.

At Little Rapids the output for March was 120 tons with an average of 21 men. This number of hands however includes woodchoppers, teamsters and other outside employees.

The Du Lievre Mining and Manufacturing Company are making extensive improvements on their property at Bassin du Lievre. A very large and powerful new water wheel is to be put in. Altogether the company will push for a large output from their mine.

We learn that the Glasgow Phosphate Company have suspended operations at their mine, pending the settlement of some difficulty between the management and the Scotch Board.

It is expected that navigation on the Lievre will be resumed about the 25th of the month. The steamers *Agnes*, *Eva* and *High Rock* have been in the stocks all winter, and have been fully prepared for the season's work.

California has produced in gold between 1843 and 1886, one billion, two hundred million dollars in coin value.

MINING NOTES.

Nova Scotia.

A decision of much importance to gold miners in the Maritime Provinces has just been made by Judge Smith, at Halifax, in an Appeal against the decision of the Commissioner of Public Works and mines for the Province of Nova Scotia, in which an application for a gold prospecting license was refused to two parties named Cameron and McLeod. McLeod's application was as follows:—

"Please find \$1.50 for a prospecting license of three areas described as follows: Beginning at a stake marked W. M. L., standing about one mile westerly from Malaga Lake, in the County of Queens, thence southerly 250 feet, thence easterly 450 feet thence northerly 250 feet, to the place of beginning, containing three areas."

Judge Smith in his verdict says:—

"I do not regard the decision appealed from as deciding any conflicting claims of parties applicant, as the Commissioner does not appear, as far as we can gather from the papers before us, to have granted a license to any one; but simply to have decided that the application of McLeod was not in accordance with the provisions of sections 16 and 39 of Chapter 7 of the Revised Statutes 'of Mines and Minerals.' On referring to these sections it certainly does appear to my mind that they were framed by the legislature for the purpose of preventing mistakes or misapprehensions, and to compel applicants for prospecting licenses clearly to define the exact locality of the area or areas upon the ground; at least, that, at the time the application was made, some definite stake or starting point should be given, from which the areas could be ascertained. The two sections referred to, and upon the provisions of which the Commissioner alleges that he based his decision, seem to be very clear. The 16th section says, 'every application shall be in writing, defining the area or areas applied for.' The 39th section refers especially to prospecting licenses, and provides that 'all applications for prospecting licenses shall accurately define by metes and bounds the lands applied for.' It can hardly, I think, be reasonably urged, that if it appears as it does in this case, that when the stake or spot indicated in the application as the starting point from which those metes and bounds are to be ascertained does not exist on the ground, the areas are accurately defined, as required by the express words of the statute. One cannot read the whole of the statute without perceiving how careful the Legislature was in striving to avoid difficulty or confusion with reference to the rights of applicants. It must be evident if the application of McLeod can be held to be such a valid one as would compel the Commissioner to grant him a license, the words I have designated requiring an accurate definition of the areas, may be struck out of the statute as being useless verbiage. If this application could be held to be a legal one, it would have been equally good if the application stated the areas to lie near Malaga Lake, and the party would only have to find some areas anywhere near the lake, put a stake down, and claim a prospecting license starting from that point, and which may cover an entirely different area than he first intended when he made his application. I think it would be contrary to the policy of the Legislature, and most unwise to uphold such a contention. Therefore, I think, the appeal should be dismissed with costs."

The iron, steel and coal interests of the Maritime Provinces are asking modifications in the tariff to further protect and develop them.

We are informed that Mr. George Forsythe, of Halifax, has purchased the gold mine at Cochrane Hill, Guysboro, formerly owned by Messrs. McKenzi, Archibald and Caffrey.

The old Hall-Anderson mine is now run by the Egerton Gold Mining Company. Work has been started on the McGilligan lead which is 2 feet thick.

New Brunswick.

Albertite, which was at one time worked somewhat extensively at the Albert mines, Albert County, was first discovered by accident about the year 1850. The vein which was worked out about six years ago occupied an irregular and nearly vertical fissure, and varied from 1 inch to 17 feet in thickness. It was mined to a depth of nearly 1,500 feet, gradually running out as it descended. This remarkable mineral, occurring in connection with calcareo-bituminous shales or pyrochists, has been regarded by some as true coal, by others as a variety of jet and by others again as more nearly related to asphaltum. It resembles the latter closely in appearance, being very black, brittle and lustrous, with a broad conchoidal fracture, and like asphaltum is destitute of structure, but differs in fusibility and in its relation to various solvents. It differs from true coal in being of one quality throughout, in containing no traces of vegetable tissues, and in its mode of occurrence, which is that of a vein and not of a bed. It is estimated that the total amount of albertite raised was not far from 200,000 tons, the price of which varied at different times from \$15 to \$20 per ton. It was principally used for admixture with ordinary bituminous coal in the preparation of illuminating gas. For this purpose it was admirably adapted, yielding per ton 100 gallons of crude oil or 14,500 cubic feet of gas of superior illuminating power.

Satisfactory reports continue to be received from the Manganese districts.

Quebec.

A meeting of the Anglo-Canadian Asbestos Company was held at Montreal on Monday the 14th inst., but all information as to what transpired has been refused by the company.

We understand that signs of vigorous activity once more prevail at the British Iron mines. Furnaces for the smelting of the ore are presently in course of erection, and when completed it is estimated that steady employment will be found for a large number of men. It is also currently reported the management contemplate the erection of a tramway from the mines to the Ottawa River. This will be operated by horsepower and will greatly facilitate the transportation of the ore from the mines to the Canadian Pacific Railway.

A new shaft is to be sunk on the St. Onge gold mining company's property. The find of gold during the winter has been sufficiently encouraging to the proprietors to stimulate their search higher up on the river bed. Some of the gold taken out is very large and nuggets weighing from 1 dw't to 1½ ozs have been found.

There is very little doing as yet at the Asbestos Mines. Within the last few days the Thetford people have put on some men to clean up and shovel out snow from the open cuts, and they anticipate starting mining operations in a week or two.

At the Anglo-Canadian Asbestos Company's mines about 25 men are presently at work, and the daily output is about two tons per day. In a week or two the hands will be increased and operations pushed vigorously. The machinery and drills at these mines continue to give every satisfaction to the management.

It is anticipated that this season the output of asbestos at the various mines will be somewhat in excess of that of last year. There are indications of an increased demand and prices remain steady. An advance on last year's figures is predicted. Miners report that they have already sold considerable quantities of their prospective output for the ensuing season.

Development work is being vigorously pursued on the property of the Vileueve Mica and Mining Company near Buckingham. Machinery of the latest and most approved pattern is in operation and the deposit which is of the purest and clearest Muscovite is apparently unlimited in extent. Six good strong veins are to be found on the side of the hill. The value of this property with its many fine buildings and improved machinery is inestimable.

Ontario.

The Anglo-American Iron Company which owns about 200,000 acres in the County of Hastings, largely mineral land, and by whom it will be remembered the Central Ontario Railroad, running some 100 miles northward from Lake Ontario, was constructed, has decided to extend the Road north-westward from Coe Hill for a distance of 150 miles until it meets the C.P.R. at North Bay. The country thus to be opened up is said to contain large deposits of Bessemer ore and to be well timbered.

The Syndicate which is largely composed of Canadian and American capitalists has an authorised capital of \$10,000,000. \$5,000,000 of which is for the railroad. The ore already taken from the principal mine at Coe Hill has not proved altogether satisfactory, being too high in sulphur and requiring to be calcined before using, with the result that shipments from Weller's Bay last year were very much reduced. The work of construction of the new line will be commenced early next month, and will be pushed through to completion.

A local exchange announces that Mr. Martin Conroy, of Sudbury Point, owner of one of the copper mines to the north of that village, is negotiating the sale of his interest in the mine to Mr. Richey, of New York, for the sum of \$20,000. The property, which is some six miles north of Sudbury, was discovered last fall.

Mr. Richey has now a gang of about 70 men busily engaged in excavating copper ore out of mines purchased some time ago, and has immense quantities on the ground ready for a crusher which he is importing.

The Royal Society of Canada have submitted a memorial to Sir John Macdonald praying for the consideration of increased museum facilities at Ottawa. Prof. R. Bell states that the number of papers already promised for the Society's Annual Conference in May is largely in excess of former years.

The Kingston and Pembroke Iron Mining Company has been organized, with a capital of \$5,000,000, for the purpose of developing the iron ore district on the line of the Kingston & Pembroke Railway Company. The company owns 8,000 acres of mineral land between Kingston and Renfrew. It has three mines in active operation, and other openings will be made within a short time. Henry Siebert is President of the company, and among the principal stockholders are Samuel Thomas, Calvin S. Brice, J. O. Moss, Alexander J. Smith, H. H. Porter, R. R. Cable, S. P.

Flower, H. H. Hollister, James Tillinghast, George A. Kirkpatrick and Charles F. Gldersleeve, of Kingston; William Polluck, of Cleveland, and John S. George, of Milwaukee. The entire amount of stock has been subscribed, but the formal organization will not be announced until the company has been chartered at Kingston under the Canadian law.

The C. C. Mining Company have introduced into its works at the Cliff, and also at the Stobie mine, machinery worked by steam for the purpose of extracting the ore.

The silver mines on the Sturgeon river in Nipissing district, are attracting considerable attention among mining speculators as spring approaches. James Holditch, Esq., the owner of the Temogawing Mine has employed James McAvoy, P.L.S., to proceed with his staff to execute survey and plan. Mr. Walter Cockburn will probably take steps to develop his mine at Cross Lake as soon as the snow disappears.

PORT ARTHUR DISTRICT.

Work has been resumed at the Silver Creek Mine.

The *Miner* states that there are persistent rumours that Silver Islet will be once more placed in operation in the course of a few weeks, but they cannot be traced to any reliable source.

The Heron Bay Mine will be worked as soon as the spring opens.

We learn that Mr. B. W. Harris, for some time editor of the *Miner*, has been compelled to sever his connection with the paper through pressure of other work.

Operations are to be immediately resumed at the Huronian mine, and new machinery has been shipped from New York and Chicago. It is expected that the mill will commence work about the 1st of May. Chlorination works are to be erected during the summer.

The proprietors of R.51, situated near Silver Mountain, Messrs. P. M. French, W. C. Dobie and others, have announced their intention of driving an adit level on their property during the summer and putting it in a proper state of development to ascertain the value of the location.

Manitoba and North-West Territories.

A meeting of the Board of Directors of the Canadian Anthracite Coal Company was held at St. Paul on the 31st ulto. It was reported that as soon as work on the pockets at the mines was completed a commencement would be made with the shipment of coal for the season. 1,500 tons will be shipped to San Francisco at an early date. It is proposed to increase the number of men, and during the summer it is expected that between two and three hundred men will find employment at the mines.

At Anthracite Station the Canadian Pacific Railway have constructed a new siding for the company, a post-office has been established, and a large number of new buildings have been erected. The Annual general meeting of shareholders will be held at Banff in August.

British Columbia.

A new Hydraulic Mining Company has been started on the Fraser River about eleven miles above Lillooet, called the Fraser River Cable Mining Company. The system they intend working it on is new in this part of the country. They take the water out of the creeks by means of hose or pipes suspended from a cable stretched across the river.

At a general meeting of the shareholders of the Quesnelle Quartz Mining Company, held on the 10th ult., Messrs. James Reid, R. J. Skinner, Joseph Mason, J. F. Hawks, W. A. Johnston, George E. Filmore and William Morrison were elected directors. The secretary and manager's reports were very satisfactory. Several vein specimens of quartz taken from the shaft were shewn by the president at the meeting.

The Big Bend region is practically unprospected, but the mineral claims recorded, lie for the most part, around the headwaters of McCulloch and French Creeks. The numerous gulches and ravines generally run in an easterly and westerly direction and have cut the ore in the belt often at right angles. In other places there are outcrops on the hillsides. Specimens from both these occurring ores have proved to be rich; some show gold to the eye. Most of the ore seems to be auriferous milling ore, but whether it will preserve that character when sunk into or turn to less tractable ore, or, as some conjecture, to silver bearing ore of some kind, possibly argentiferous galena, cannot be stated at present. Nor is it known, of course, yet, how many, or whether any, of these recorded mineral claims are veins of a kind and quality that would pay for working. Very remarkable results are obtained in this business from the improved methods of modern days. For instance, it is found that in the colony of Victoria, Australia, crushing auriferous quartz pays if it contains as much as 5dwts. of free gold per ton—that is of gold not associated with pyrites. When it is associated with the less tractable forms of pyrites $1\frac{1}{2}$ oz. to 3 oz. are required; but speaking broadly Victoria has made its fortune out of gold deposits which yield on an average less than *half an ounce* a ton.

There are apparently mineral veins at Big Bend; small parcels have assayed from \$50 to \$150 a ton; the mining region is near a great navigable river crossed by the Canadian Pacific Railway; the climate is not severe; there are arable and hay lands and three months summer hill pasture, also abundance of wood. With a steamer on the Columbia the mines would be within two days' reach of the above railway. Under these circumstances, every effort should be made to ascertain the true character of the ores and the size of the mineral veins in a district in which all mining conditions are so good.

The following is a copy of an assay of ores from a group of veins at the Ille-cille-waet section, made by an American capitalist, who proposes to return in the spring:—

No. 1.....	\$126.25	Silver per ton.
" 2.....	175.82	" "
" 3.....	31.05	" "
" 4.....	50.00	" "
" 5.....	84.08	" "
" 6.....	60.80	" "
" 7.....	59.00	" "
" 8.....	609.00	" "
" 9.....	41.68	" "
" 10.....	384.77	" "

Mr. F. Jones, Gold Commissioner at Clinton, estimates the gold yield taken from the Lillooet district during the past year thus:—

A. W. Smith.....	\$57,900
F. W. Foster.....	16,517
E. Bell.....	13,700
All other sources.....	43,883

\$132,000

Work is to be immediately resumed at the Foster Quartz mine. The mill is now completed and a number of experienced miners from California have gone to the scene of operations.

The Big Slide mines which comprise the properties of this company were discovered through the enterprise of Mr. F. W. Foster, of Clinton. A piece of heavy sulphuret ore was given him by an Indian, in 1872, which assayed \$28.50. Mr. Foster sent an old miner to try and find the ledge and locate it; this he was successful in doing; work was begun, and tunnels run to tap the ledge. In the lower tunnel this was done at a distance of 243 feet, and in the upper tunnel at 80 feet, at each point of contact a strong ledge of good quality was found. Mr. Chenhall, a practical Cornish miner, erected an arrastra, with which to work the ore; it was not built correctly and the limited supply of quicksilver was lost. 900 pounds of the ore were crushed at this time, the small portion of remaining quicksilver and amalgam yielded in gold \$12.50, and a prospect could be got of the tailings nearly as good as before milling.

Of the work done during the past year, Mr. Geo. Henderson, the Superintendent of the Company, writes:—"During the past summer I put a few men to work taking out ore for shipment to San Francisco for treatment to determine the value and best modes of working. The tests made in San Francisco were deemed sufficiently encouraging to organize a company and go to work in earnest. The approach to the mine being very difficult, a large outlay of money was necessary to build a road, over which to haul machinery, &c. This road is now completed, and the machinery for a modern ten stamp gold mill and corination works are now on the ground; by the new year, if no unforeseen delays occur, the mill will be erected and running. The mines are now being opened up for permanent work. The levels are being connected by upraises to insure a good circulation. Drifts are being driven on each level. In all parts of the mine so far worked, fine paying ore has been found, which improves as the mountain is pierced. Everything gives promise of an immense body of ore. The main vein is from 15 inches to 5 feet in width. The average value per ton is about \$20 gold and \$2.50 silver. By the method of reducing that will be used, 90% of the gold and silver in the ore will be saved, at a cost of mining and milling of about \$5 per ton. Work goes on in the mine day and night, and by the time the mill is ready, the mine will be sufficiently opened to furnish all the ore necessary to keep the mill constantly at work. It is the intention of the company to enlarge the mill as soon in the spring as possible—the grading for the additional stamps is completed. Two desulphurizing furnaces are now in course of construction. There are on the pay roll of the company fifty men, employed as miners, carpenters, and men employed at the saw-mill. We have burnt a kiln of 67,000 brick; they are of a very fair quality, and will be used in the construction of our furnaces, &c."

Personal.

Mr. R. W. Ellis, M.A., of the Geological and Natural History Survey, has been granted the L.L.D. degree by the corporation of the university of McGill. Ever since his graduation as a Bachelor of Arts at the same university when he carried off the Logan gold medal, Mr. Ellis has been actively and successfully engaged in Geological work in Canada, so that not only is the honour which has been conferred upon him by that university a deserved one, but one which makes a crowning point in the successful issue of his arduous labours in developing so important a branch of research in the country. The subject of Dr. Ellis' thesis to the corporation was "The History of the Geology of New Brunswick," a subject which his long experience in that section of the Dominion eminently fitted him to handle in a masterly manner. We extend to Dr. Ellis our hearty congratulations.

Professor Macoun, of the Geological and Natural History Survey staff, has gone to British Columbia, where he will be located during the summer.

Mr. C. B. Wright and other gentlemen interested in the establishment of smelting works, in connection with the mines in British Columbia, have had an interview with the Customs Department at Ottawa. They want admission free of duty of the peculiarly constructed machinery required for this purpose in the Province. The works are to be erected in the Selkirk range and other parts of British Columbia, which are rich in minerals.

CHESTNUT.

[Iron Trade Review.]

We observe an article now going the rounds of the papers regarding "A Cat on a Fly-wheel." This time the venturesome feline is located in an electric lighting station at Brooklyn. Isn't it about time to give poor Tom a rest? With only slight changes as to locality and circumstances the same item has been a staple article for clipping for the past ten years or more. One week, in Cincinnati, he travels 300 miles at the rate of 45 miles an hour and drops off in a limp and sell-me-out-for-five-cents condition; the next week finds him in Chicago, clinging for ten hours to the rim of the wheel and then hopping off at night as chipper as ever; anon he gets a free ride in Detroit and, when attempting to take a leap for life, strews the engine floor with yowls and violin strings; next he turns up in Denver with a sore throat and watery eyes, ready to go to sleep on the rim of the first fly-wheel that offers. If this thing doesn't stop, we shall next hear of his taking a trip from New York to Chicago on the drive-wheel of a locomotive and yet surviving to tell an admiring feline audience of his wonderful achievement.

Mineralogy, Geology & Science.

All correspondence under this head, and scientific exchanges, must be addressed to the Science Editor, Canadian Mining Review.

Omitted.

Through the unfortunate illness of Professor Marsan we are unable this month to furnish our readers with the concluding portion of that gentleman's paper on "The Chemical Aspect of the Metallic Minerals." We hope to do so in our next issue.

The Great Ice Age and Subsequent Formations at Ottawa, Ontario.

By H. M. Ami.

Of the Ottawa Field Naturalists' Club.

Among the most interesting and captivating subjects which attract the attention of even a casual observer in the realms of geological science, few of them are as full of interest and afford as much information as the researches in the most recently deposited or newer overlying strata. Besides this interest, there is carried with it the fact of its practical importance, so that the economic aspects of the question have likewise to be taken into consideration.

They are numerous, the questions which press themselves one upon the other in examining the *marls, sands, gravels, clays, boulders and kindred materials* of a district, and as this region which it is the province of the O. F. N. C. to examine, is particularly rich both in the extent and the distribution of such materials as have just been enumerated, the questions arising out of these Post-Tertiary deposits are themselves likewise rich in diversity, and scope. The following are some of the more important of these which we will attempt to consider and which naturally present themselves to one's mind:—

I. *At what period in the Earth's History did the Glacial Epoch or the Great Ice Age make its appearance?*

II. *What were the causes which led to this extensive reduction in the temperature?*

III. *What features characterized it and how long did it last? What, the phenomena of glaciation?*

IV. *What traces did it leave behind?*

V. *What was the condition of things subsequent to this epoch?*

VI. *To what extent was the continent submerged?*

VII. *For what period of time did this subsidence last?*

VIII. *What features characterized this period of submergence?—(marine life, etc.)*

IX. *What are the unquestionable proofs of the subsidence which was followed by a period of elevation? Besides these,*

X. *It will likewise be necessary to consider this period of elevation which carries us on to the present day, during which time numerous and varied lacustrine or aluvial deposits were laid, and in the lapse of which, man—aboriginal man—made his appearance; and, the questions which press themselves round this last point are exceedingly numerous indeed, and would of themselves form a worthy theme for a voluminous work.*

XI. Then, in which of the newer deposits are these traces of the existence of certain tribes of the American Indians found? What are these traces? To what extent do they assist in forming an estimate of the degree of civilization to which these aborigines attained? What customs, manners and modes of life are exemplified by the implements of various kinds found in what has been very appropriately termed in various countries the *Human Period*? At what time and how long did these inhabitants occupy the land before the intrusion by the whites, the causes which led to their disappearance in certain portions of the country and what was their history? *All these*, are only a few of the more salient problems suggested, and to which reference will be made.

* * * * *

But before entering upon these fascinating studies it may not be thought amiss to note what has already been done in the particular field of research with which we have to deal. In the "Geology of Canada," 1863, a report by Sir Wm. Logan and staff—there is incorporated in that admirable work a lengthy chapter on "superficial geology" in which a number of interesting notes are recorded from Ottawa and its environs, an examination of which had been entrusted to Dr. R. Bell. Then comes the work done in the Post-Pliocene geology of Ottawa by Dr. J. A. Grant which produced a number of valuable papers, some of which were published in the United States and others here in Canada. At the mouth of and along *Green's Creek*, but six miles distant from the city, and a favourite resort for students of Post-Tertiary geology, not only has Dr. Grant, but Sir William Dawson himself also has investigated and reported important discoveries. The collections of the late Dr. E. Van Cortland show that he too, devoted considerable attention to these interesting deposits, whilst the late Mr. E. Billings in his Canadian "Naturalist and Geologist" published notes on the same subject, in that valuable record of science. The above mentioned work and workers have been previous to the inauguration of the Field Naturalists Club in this city, and since its organization we have no hesitation in saying that it has been instrumental in carrying on successful excursions and sub-excursions over the district. Nearly a score of members, have at least taken a more or less active part in these researches, whilst the abundance of work and material at hand likely to be there for years and years of close examination—make it all probable that greater attention will continue to be paid to the deposits in question. The work done already is considerable; the work that is being done is not great, whilst there remains a hundred-fold more to do than has been done up to date. As many are well aware, our worthy "City Engineer" Surtees has been carrying on an extensive series of excavations in all parts of the city, from Sandy Hill to Ashburnham Hill, and from Stewarton to the Ottawa River, on one side, or from Sandy Hill to the Ottawa and Rideau Rivers on the other side of the canal, and that for the past two years. These excavations or trenches are dug or blasted out to a depth ranging from *eleven feet to eighteen feet six inches*, so that not only have deep but also interesting sections been afforded the writer and others, exhibiting the different kinds of strata and the material which compose them together with the fossil remains which occur entombed in the same.

Now, to begin with the description of these Post-Tertiary or Post-Pliocene (Pleistocene) deposits in this part of the country, as in any other portion, it is first necessary to ascertain,

whence the material came which composes them, and in order to do this it is obviously necessary to examine the older rocks of the district, see of what nature of rock their measures consist, and know the stratigraphical relations existing between the various members of these older underlying series.

Just as we have a great diversity of formations about Ottawa, so also have we a great diversity of substances in the material which makeup the rock of the Post-Tertiary deposits, (and let it be borne in mind, that in using the word "rock" it is used in its true geological sense, so that a handful of sand, a lump of clay, a mass of boulders, cemented or not by finer detritus, are all as much "rock" as a pillar of freestone, a block of limestone or a column of granite). Most of the materials which are found in these newer deposits were derived from the older formations of the district, whilst erratic blocks, and the like, may have come from great distances. To go into details as to what are all the various kinds of rocks met, would necessitate a long and protracted study of a great quantity of material which would form the constituent elements of all the formations from the *Laurentian* to the *Hudson River* as they are developed in the "Ottawa Basin;" from the gneissoid, granitic and hornblende rocks of the former, to the shaly magnesian and arenaceous measures of the latter. There would be included: the crystalline limestones, serpentines, dolomites and diorites of the *Middle Laurentian*, occurring at Chelsea in the Laurentide Hills, there would also be included portions of the conglomerates and quartzites and calc-bearing sandrock materials peculiar to the unconformably overlying *Potsdam* and *Calceiferous formations*, whilst the sandstones, shales and limestones of the *Chazy* followed upwards without a break by the impure calcareous strata of the *Black River* and *Trenton formations* would all be mixed together with the likewise conformably overlying bituminous schists of the *Utica*.

The materials which compose the series of formations just mentioned and newer than the *Laurentian* were themselves derived from the *Laurentian System*, for this latter contains all the elements necessary for the formation of the *sandstone, shales and limestones* of the newer overlying Cambro-Silurian strata.

Having thus ascertained the series of strata whence the material was obtained which constitutes the various beds or divisions of the strata in the Post Tertiary deposits, let us consider the condition of affairs previous to and at the coming in of the Glacial Epoch.

(To be Continued.)

The Yukon Country.

Interesting Sketch of Previous Surveys.—The Mineral Resources of that Vast Canadian Inheritance in the Extreme North-West.

Until the United States of America acquired that western portion of this continent, known as Alaska, its topography, to a great extent, had been neglected, except along its shore lines, and for a short distance inland in some places; the Yukon River Valley being the only portion of the country known, and that only imperfectly. Alaska at that time was to the outside world a veritable *terra incognita*. Simultaneously with the descent of the Imperial Eagle of Russia and the hoisting of the Stars and Stripes at Sitka, in 1867, was the idea of exploring

that "land of the midnight sun" promulgated. Many will remember the long and fierce debates, both in the Senate and Congress, upon the wisdom of paying to Russia the sum of \$7,200,000 for that north land. The opponents of the purchase characterised the country as a "useless pile of mountains and glaciers which possibly might, at some future day, supply the United States with ice quarries." However, that far seeing statesman, Secretary Seward, secured for Uncle Sam that valuable tract of country, which, from its position, ought to belong to the Dominion of Canada, and by many termed "Seward's folly." There are living to-day some of his brother legislators who are ready to acknowledge that, at least, there was "wisdom in his madness." Take, for instance, into consideration the acquisition of the valuable sealing grounds leased from the Government by the Alaska Commercial Company for \$350,000 per annum, a sum sufficient to pay interest and contribute towards the Government of the territory. Then again there is valuable mining interests being developed. At present one of the largest and most complete quartz mills to be found on the continent is there in successful operation—both mechanically and financially. And it is gratifying to the inhabitants of that new country to be able to point to developments which prove that there is scope for many more.

Although many exploring parties have, from time to time, been fitted out and sent by the United States Government, yet but little of a valuable character had been collected up to the time that "the special agent," Ivan Petroff, made his report in August, 1882. That gentleman has given a deal of information in regard to Alaska and its people. But when we take into consideration the extent of country drained by the great Yukon, it can be at once understood that one or two parties can do but little in a year or so in the way of giving the public a correct topographical description of that far distant country. Since Petroff's time Lieut. Schwatka and latterly Lieut. Stoney have done much, coupled with the expeditions under them, to furnish desired information. These travelers and explorers have received from private sources,—gentlemen, resident in the interior of the country for a number of years—much detail of a valuable and practical nature.

A few traders have established a trading post at the confluence of the Stewart and Yukon which they have named Fort Nelson. No doubt the advent of quite a number of miners, and the amount of gold which they were obtaining from the bars on the Stewart River induced the establishment of this trading post, which is about 70 miles east from the Alaska boundary. In order that the reader may better understand the relative positions and distances of points of importance along the mighty drainage artery, flowing at least 1,000 miles in British Territory, thence 1,600 miles through Alaska, with in places of 20 miles, embouching by a number of mouths into Norton Sound, a part of Behring Sea. As few facts regarding its mightiness may be mentioned. It has been stated, and it may appear incredible to those who have been taught to believe that the Mississippi is the father of waters, to be told that the Yukon River discharges every hour one-third more water than rolls by New Orleans during the same time. Strange as it may appear sea going vessels cannot get nearer the mouth of the river than some 50 miles, on account of the immense quantities of silt carried down by the freshets. The port of St. Michael, situated some 60 miles north from the river, is the depot for the Yukon River and

Arctic Trade, and is visited by the Alaska Commercial Company's steamers two or three times during the summer. At this point the company's river steamer loads cargo for the interior, taking on board 40 axe men to cut fuel on the trip up, whose mission it is, as soon as the steamer touches the bank, to rush, axe in hand, to the nearest drift pile, so that the craft may be detained as short a time as possible. Reaching Fort Yukon, a distance of about 1,200 miles from Saint Michael, in 22 or 23 days, and Fort Reliance, 400 miles further up the stream, in 6 or 8 days more, makes the length of the average trip 30 days. Notwithstanding the number of hands employed, and the length of time occupied in delivering goods at Fort Reliance, the freight rate charged is remarkably low, viz.: \$80 per ton, so that Harper & Co. are supplying provisions to the miners at Fort Nelson at a very reasonable price. There are about 70 wintering at and near that point at present. Last fall flour was sold at \$14 per 100 lbs., bacon at 30 cents per lb. and other staples in proportion. By the aid of a small steamer, which Harper & Co. bought from Schefflin Bros., who took it from San Francisco to Yukon for the purpose of using it in prospecting for gold, the owners are thus enabled to distribute and furnish supplies to miners at considerable distances from their depot.

It is scarcely creditable to our Federal and Provincial Governments to have to depend upon the exploration pushed forward by a foreign power to obtain information of one's own country; but so it is. It may be asked what is the country good for if explored tomorrow and a topographical description published? Commencing some six years ago a small stream of gold hunters flowed into the north-west portion of the Yukon country, and every summer since miners have visited it in search of the precious metal with more or less success. During the early part of last spring and summer over 200 miners purchased supplies in Alaska and went by way of Chilkoot to different streams where gold had been discovered, but principally to the Stewart River where the best pay had been found. For a portion of last summer Harper & Co.'s steamer, *New Rackett*, was used in raising water for a mining claim situated on this stream, and although tailings were being worked a third time, by the aid of sluices over \$20 per day to the hand for all employed was the result up to the end of the season. Others were mining on the Salmon below Lake Lebarge, while it is reported that on the Lewis River there were but few blanks drawn in that camp during last season. Some 70 men took up winter quarters at Fort Nelson and Stewart River, expecting to take out gold in the fall and early spring. The writer was informed by several gentlemen who had examined a very large bar of about four miles in length, some 30 feet deep and of considerable width, that it prospected throughout the whole gravel from 1 to 5 cents to the pan. This bar is on the main Yukon below the mouth of Stewart River, but the difficulty of working is the lack of water. That necessary agent can be obtained some 25 miles distant at a large outlay, but as wood is plentiful it might be less expensive to employ steam power to raise the required water. At any rate it is agreed that there is a big thing in the bar if water was only brought upon it. It is said that there are many other bars that prospect well, and that at no distant date will be worked profitably. It is believed that inside of the next two years over 1,000 men will be mining and doing well on White River. A great mining future is predicted for this great unknown land.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place shall not exceed forty acres in area. Its length shall not be more than three times its breadth and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as afore-said; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should a person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench creek or bill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:— "Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR

Comptroller, N. W. M. Police.
Ottawa, March 25th, 1887.

Department of Inland Revenue.

An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

OFFICE:

UNION CHAMBERS, 14 Metcalfe St.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 17th of the month.

For correspondence, &c., to the Publisher, the CANADIAN MINING REVIEW, Ottawa.

Advertising Space.

The circulation of the CANADIAN MINING REVIEW, which has steadily been going up since its first publication, more than five years ago, has now more than doubled the estimate upon which we had reckoned, and its value as an advertising medium to business men who wish to reach the best classes of mine owners and operators, and the mining centres and camps of every province in the Dominion, is consequently very greatly enhanced. The REVIEW is in the widest sense a Canadian journal belonging to all provinces alike; it is the only journal published in Canada wholly devoted to the interests of her mining industries and mineral resources. We would simply draw the attention of those who have hitherto overlooked it, to this matter, promising our best attention and most reasonable terms on any application for advertising space.

The Nanaimo Disaster.

The announcement and details of the terrible colliery catastrophe at Nanaimo has naturally created throughout the length and breadth of our Dominion a feeling of deep sympathy for the large number of unfortunate families who have thus so suddenly been bereaved. Out of a total of over one hundred white men and nearly seventy-five Chinese, only six have been brought out alive and these are more or less injured. In Victoria and other portions of the Pacific province a fund for the relief of the sufferers has been organized, and we feel sure that our readers in the sister provinces will also come forward and augment it with liberal contributions. Great suffering exists and practical assistance is wanted in the worst way.

Until the result of the enquiry, which has been instituted by the Hon. Mr. Robson, Minister of Mines, has been made known, the cause of the fatal explosion can only be con-

jectured, firedamp, coal dust, insufficient ventilation, carelessness on the part of the unfortunate miners, ineffective machinery and the like, are causes that have been hinted at. In the meantime a searching investigation should be made with a view to adopting preventive measures for the future.

Protection to the Mining Industry.

This can be accomplished in more ways than that which is generally understood to be the most desirable means or by an increased duty on importation to enable our minerals to be mined and smelted in our own country for our own use. That is one only of the measures, and we have no intention of under estimating its value, hence it is mentioned first as being the most important and that most easily adjusted to the requirement of all concerned. At the present time our metallic ores are mined with the object of supplying foreign markets, and little, comparatively, is utilized for local use, which is the more desirable method to pursue in order to receive the full benefit incidental to smelting and manufacturing them into the metallic state. The minerals requiring revision under tariff regulations are coal, iron, copper, lead, zinc, sulphur, and clays.

The other demands for protection are from evils that exist under, and that are incidental to, a wrong system of selling minerals along with the surface soil or agricultural right to Farmers and Speculators, and without regard to Citizenship. In doing so our Local Governments have sold an area of some millions of acres of our best mining lands, and these have passed into the hands of foreigners and non-residents, and no condition or provision is made by the Government so selling them, that these minerals will be developed and worked. But such is not the case with Dominion land homesteads, for provisions as to citizenship, location on the ground by possession, and development, are made compulsory. Are not mining lands worthy of the same protection as Dominion farming lands? Protection is required from an evil in the form of fraudulent schemes started and promoted by parties who are not mining men, but having a local knowledge of a district they may become associated with mining men and thereby gain a mere smattering of the business. Often they are American importations, and at times a combination of local and imported talent, who present a prospectus of a mining company with glowing accounts of "millions of tons of ore in sight that require nothing in outlay to market" "it but the mere blasting of it out of a mountain side!" or words similar to that and with that meaning. On such an untrue picture funds are secured and work and time prove, for it is reported by one of the company, that instead of costing only the actual expenses of mining the ore, it has actually cost \$20,000 to open one of the mines! The large mountains of ore do not roll into the railway cars as plentifully nor as fast as was promised, no

dividends are paid from mining the mountains of ore, or if any are, they are not from profits. Another dying or last attempt is made of still greater things a little further off which requires possibly railway extension and only a few millions of dollars, and such are the means used to bring ruin on what might be a workable scheme if conducted on business principles and with a regard to the true condition of affairs presented.

They may even not scruple at advertising to own a property they have only a half interest in! By such dishonest means some \$2,000,000 to \$5,000,000 of capital is sought to be invested in a manner we call neither legitimate business, honestly represented or a correct way of doing it.

The periodical, and now in Canada, historical mining excitement, is another form of fraud from which no good can result when the conditions for such, or anything to excite about, are wanting. If a large deposit, say of pyrites of low grade, or even several large deposits, are found several hundred miles from market or civilization, and in a country devastated by fire, there is certainly nothing to warrant a mining fever in that, as the conditions for successful treatment of such an ore are not found in the neighbourhood; it has therefore to be shipped to a market where it will mix with other ores and be treated so as to utilize the by products. Such a find or prospect is not a poor man's mine. To develop it is therefore interesting only to a manufacturer who can treat such an ore, and there is no money in it for the poor prospector as it cannot be worked on a small scale as easily as on a large one, and its value even to the manufacturer is a question of properties, freights and value, hence the folly of a mining excitement over such a discovery. It cost only \$500,000 to prove the truth of this in the Province of Quebec with similar ore and better conditions. Hence the ore is only a shipping ore and subject to competition in freight with other ores of a similar kind, which can be obtained nearer a market. We cannot see any reason why such an ore should cause a mining excitement. It is quite different where gold is discovered in alluvial diggings. There is nothing in it to warrant an excitement save only in the fertile brain of a schemer who desires to "sell" somebody in selling claims. It is only a question of freights, quality and price, like any other trade commodity dependent on supply and demand. Thus we have referred to protection by tariff revision; protection to mining lands against foreign or alien owners; protection against the locking up of mining lands; protection against fraudulent prospectuses of "Wild Cat" schemes and schemers; protection against false pretences and fraud; protection to capital from the employment of those who are ignorant or not trained to mining as a business, and the list not being yet exhausted will be continued in our next issue.

A National and Rational Policy.

The Budget Speech of Sir Charles Tupper and the welcome revision of the Tariff, with regard to the interests of the mining section of the community, are matters that must create an expression of pleasure among the readers of the CANADIAN MINING REVIEW. It is a fitting introduction to our appearance this month in a new dress, and is an event long to be remembered in the history of the mining industry of Canada. The law or action of the Government, that is productive of a national feeling of patriotism in preferring the product of the labor of our own country to the imported product of the labor of aliens or foreigners is a national policy. The law that encourages individual energy and the development of the manual and brain power of the community in the direction of producing the necessities of life from the natural products of our own country is a wise enactment. The law that converts our foreign trading importers into "home" manufacturers is the motive power of an incoming tide of national prosperity. The law that makes a foreign sympathising merchant an employer of Canadian labour, helps to build the hive of a national industry bound together by the strong bands of rightly directed capital and labour. The law that stimulates and encourages individual industry or effort in a right direction or cause, and restrains from a ruinous or wrong course is the law desired for the development of our Canadian mining industries. It cannot be expected that the home demand for iron can be supplied from local furnaces and mills until such time as sufficient of these have been constructed, but when that is done and the home industry is established, the iron trade will be supplied with a superior class of ores to work with than those of Great Britain. No business employs so much labour as does iron, for (it cannot be pumped like oil or elevated like grain), it has to be handled whether in the form of ores or metal, and every time that is done it means an expenditure of ten cents a ton on the millions of tons handled over and over again during its manufacture and transportation. In this way the wages earning community are benefitted. That Sir Charles has underestimated the value and results to be derived from this new lease of life to an almost extinguished industry would not be so apparent had not the wisdom (?) of Sir Richard Cartwright drawn attention to the idea of exporting Canadian iron. Sir Richard is evidently not aware that Canadian charcoal pig iron has been exported to the United States, and is in demand on account of its superior quality if enough was manufactured during the present time to supply the demand. To all sections of the country the wisdom of the new tariff will become apparent. Probably no other country is more richly endowed by nature with such stores of iron, and in offering these inducements to capitalists to develop our iron resources the Dominion will find it to pay well.

What we want now is the much needed enactment of proper timber and mining regulations by the local legislatures.

The Use of Crude Phosphate.

The value of raw phosphate as a fertilizer is a subject that has created much discussion, but without, as yet, obtaining decisive results. The prevailing impression is that the crude phosphate is valuable for "a long pull" and gives out its good effects slowly during two or three years after its application to the soil, whereas the superphosphate, which is phosphate reduced to a soluble condition by admixture with sulphuric acid, produces its full effect during a single season. The preparation of the acid is expensive and agriculturists are suspicious of manufactured fertilizers, for doubtless they are sometimes fraudulently prepared. If the value of the crude phosphate can be established, it would provide a cheap fertilizer in a form that would secure confidence, and the use of it would become greatly extended to the advantage of our miners and the benefit of the farmers.

Prof. N. S. Shaler, of Harvard University, has taken a great interest in the subject and is confident that simple methods may be found by which phosphates may be made available as manures without treatment with sulphuric acid. He proposes that thorough experiments should be made and will arrange for their trial at the Bussey Institution, an Agricultural Department of Harvard University under the care of Prof. Storer. The Bussey Institution would provide the land and the useful laboratory, and a skilled chemist would supervise the tests. The United States Geological Survey will probably contribute something towards the expense, and private firms have expressed a willingness to do likewise. If it was a product of the United States that was under consideration the whole expense could be at once provided for in that country, but as it is a matter of primary concern to Canada, it seems fitting that our Government or our miners should aid in the project.

Dr. A. R. C. Selwyn, Director of our Geological and Natural History Survey, has had his attention occupied by the subject for a considerable time and proposes in conjunction with Prof. Saunders, the Director of the recently established Experimental Farm, to commence and carry out the necessary experiments. It is much to be desired that this should be done as there are few subjects of greater importance to the country than the securing of cheap and effective agricultural fertilizers, and if the utilization of our mineral deposits can be promoted at the same time the matter assumes increased consequence.

Mr. Bowker, of the Bowker Fertilizer Company of Boston, in a recent lecture, while expressing an unfavourable opinion of the value of crude phosphate for quickly growing crops, admits its possible ser-

vice with grass and fruit trees. Prof. Shaler says the superior richness of the blue grass of Kentucky is due to the phosphoric acid in the soil, and indicates the value of phosphates as a manure. Some recent experiments with flower seeds show a great superiority of growth where crude phosphate was applied, suggesting that it is immediately effective; but such experiments need to be multiplied and the methods and results carefully watched by scientific observers before reliance can be placed upon them.

Our Government cannot do a better service to the country than by promoting this investigation, and as many tests are needed to establish the facts and unusually good facilities are offered in the proposed experiments at Harvard University, it would be well to encourage that effort also. Should any of our miners or agriculturists desire to contribute towards the promotion of the investigation in the United States they should communicate at once with Capt. R. C. Adams, of the Anglo-Canadian Phosphate Company at Montreal.

The National or Geological and Natural History Survey Museum.

Looked at from a Business Standpoint.—Economic Minerals and Mining as a Part of the Wide Field Covered.

[By a member of the Geological Survey staff.]

Recently it has fallen to my lot to glance over the fields of work occupied by the Geological Survey in the past. What led to this was the need of grouping the reports of the Survey by provinces, and the many different branches of work performed by specialists according to their general subject, in connection with the names of the specialists whose work it was desired to trace—felt as a means of inquiring into certain exhibits in the museum.

With the permission of the Director of the Survey, I have here extracted a small portion of my notes, thus incidentally made, appropriate to the field of the CANADIAN MINING REVIEW. The topic is timely on account of its suggestiveness in connection with the general subject of a national museum.

SCOPE.

I find the contents of the Geological Survey or "National Museum" building in its present state, to be classifiable,—including all that is therein presented by the older to the younger generation,—the reports of the Survey in the book room and library, along with the exhibits in the museum, as follows:—

I. *Physiographic Work*, representing all the provinces; embracing geological and geographical surveys, and field work in various departments more or less special. Reports, specimens, photographs, &c.

II. *Economic Minerals*, mining and mining geology. Analysis of minerals &c.

III. *Biological Work*, embracing—
(a) ancient and extinct life as a means of under-

standing the past and present world and its inhabitants. (palæontology.)

(b) natural history, including animated nature as far as interesting or important to mankind.

(c) botany, including forestry, agricultural plants, &c.

(d) ethnology, including human inhabitants of the country in the past and present.

IV. *Chartographic* work, embracing everything in all departments capable of being represented in graphic form, such as maps, sections and diagrams.

V. Exhibits in all the above mentioned departments; embraced in the museum and library.

WEALTH ACCUMULATED.

Any one familiar in the slightest degree with the operations of the Geological Survey will recognise at once the wealth of matter that has accumulated in each of these departments.

Omitting the more general and better represented departments (except to remark regarding them that they are all crammed to overflowing in a building not fire-proof) I will append a brief abstract of Sub-division II, the titles regarding minerals and mining since the Survey was organized. It will illustrate the character of the work done in a department not very extensively represented in the industries of Canada, and serve as an index to that industry in each of the provinces so far as represented in the museum and library.

THE WEALTH UNDER THE SURFACE.

The economic minerals form the main feature of the first floor of the museum. The arrangement is according to the uses to which they are adapted. A second feature of the same floor is the Scientific Collection of minerals, in which all the minerals represented in the Dominion are arranged according to their chemical ingredients and natural relationship to each other. A third feature of the floor is that of the Metals and their Ores (arranged in the flat glass cases along the centre of the room), and remarkable for its completeness and general excellence. Though forming Class I of the Economic minerals it is on account of its importance placed separately. The subdivisions of the Economic minerals (the balance arranged along the walls on both sides) are:—

1. Metals and their ores.
2. Fossil fuel.
3. Minerals applicable to certain chemical manufactures and their products (see also under 4).
4. Mineral manures (see also under 3).
5. Mineral pigments and detergents.
6. Salt brines and mineral waters.
7. Materials applicable to common and decorative construction.

The only exhibition beside these mentioned on the first floor is that of the rocks. It is arranged in the centre according to formations; consequently is also important to mining. Mr. Broadbent is constantly adding to the

attractions of this floor, devoting all his time to it; so that every day visitors will find in one or another of its departments something new.

PUBLISHED INFORMATION.

It is proper to remark that the library is an important part of the museum, as containing all the published information extant, and the reports of the Geological Survey describing the contents of the museum. It is open to the public, like the museum itself, and has in attendance a librarian who is always ready to produce any required report. It is only necessary to explain that the years mentioned below are part of the titles of the reports, referring to date of field work, not of publication.

MINERALS GENERALLY RELATING TO ALL THE PROVINCES.

Sir Wm. Logan was a practical mining engineer by education and experience. He never made any geological report without doing full justice to the economic minerals of the country examined. Some of his work was catalogued anonymously.

T. S. Hunt.—Mr. Hunt's catalogued reports began with that on mineral springs, ores, &c., 1845-46 and 1848-49, and embraced Ontario and Quebec minerals promiscuously down to 1869. He reported on various minerals and mineral waters, 1847-48; on mineral springs, ores, &c., 1848-49; on soils, peat, asphaltum, mineral springs, &c., 1849-50; on various mineral waters, 1850-51; minerals, soils, mineral waters, &c., 1851-52 and 1852-53; sundry analyses, manufacture of salts from sea water, metallurgy of iron, 1853-56; on dolomites, limestones, fish manures, &c., 1856-57; on intrusive rocks, minerals from silurian rocks and on the history of magnesia limestones, 1858; on petroleum and salt, 1863-66; on peat and its applications, 1863-66; on mineralogy of gold veins and method of gold working, 1863-66; notes on iron ore, 1866-69; petroleum (separate report) in Gaspé, 1865; Canada: a geographical, agricultural and mineralogical sketch (separate report), 1865. In 1867 (separate report) he published a sketch of the Geology of Canada for the Paris exhibition of that year.

Anonymously catalogued.—As appendices and otherwise, including maps accompanying the reports elsewhere mentioned, some titles occur in the "List of Publications" not connected with any authors names:

Statistics of copper mining and copper smelting in Great Britain, 1846-47; catalogues of some of the economic minerals and deposits of Canada, 1849-50; descriptive catalogue of a collection of economic minerals of Canada and of its crystalline rocks (sent to London exhibition for 1862—separate report), 1862; ditto, including stratigraphic collection sent to Philadelphia, 1876; ditto Paris, 1878; on the Goderich salt region (reprinted from the transactions of American Institute of Mining Engineers vol. V), 1876-77.

J. R. bb.—Mining and mineral statistics, 1871-72.

B. J. Harrington.—Notes on samples of brick clay from Fort Garry, analysis of serpentine, &c., 1872-73; on the iron ores of Canada and their development, 1873-74; notes on a few Canadian minerals and rocks, 1874-75; notes on miscellaneous rocks and minerals, 1876-77.

G. C. Hoffman.—Chemical contributions to the Geology of Canada, 1874-75, 1875-76, 1876-77, 1877-78, 1878-79, 1879-80, 1880-82, 1882-84 and 1885; on Canadian graphite, 1876-77.

L. Smith.—Observations on the history and statistics of trade and manufacture of Canadian salt, 1874-75.

Prof. Dittmar.—Analysis of the waters of Hayes and Nelson rivers, 1879-80.

E. Coste.—Mining laws and mining policy, 1885; in hand (assisted by Mr. Brummel) statistical report of mining operations in all the provinces.

ECONOMIC MINERALS—NOVA SCOTIA.

Logan & Hartley.—On the Pictou coal field, 1866-69.

E. Hartley.—On coal and iron ores of Pictou County, 1866-9. Spring Hill coal field 1886-9. Map in Atlas of 1863.

T. S. Hunt.—On the gold region of Nova Scotia. (Separate publication) 1868.

A. R. C. Selwyn.—Observations on gold fields, 1870-1. Acadian vein deposits, Londonderry and Colchester, 1872-3.

Jas. Robb.—On coal mines of eastern or Sydney coal field of Cape Breton, 1872-3.

Scott Barlow.—On Spring Hill coal field, with map, 1873-4. Survey of coal in fields Cumberland County, 1875-6.

W. McQuat.—On coal in Cumberland County, 1873-4.

Map accompanying reports, map of Acadian iron mines, 1872-3; index map of Spring Hill coal field, 1873-4; map of Sydney coal field, one inch to one mile, 1873-4; ditto same scale, 1875-6.

NEW BRUNSWICK.

R. W. Ells.—Borings for coal at Newcastle bridge, 1872-3. Second report on same, 1874-5. Iron ore deposits of Carleton County, with map, 1874-5.

Map accompanying reports, map of Grand Lake coal field, with older rocks in Queen's and Sunbury, 1863. Map showing distribution of iron ores in Carleton County, 1874-5.

QUEBEC.

Sir W. Logan.—On the gold of the Chaudière region, 1850-51; economic minerals from Montreal to Cape Tourment, 1852-53; the Ramsay lead mine and Acton copper mine with miscellaneous economic minerals, 1858.

B. J. Harrington.—On minerals of apatite bearing veins in Ottawa County, 1877-78.

A. Michel.—On the gold region of Lower Canada, 1863-66.

T. S. Hunt.—Mineralogy of gold veins, 1863-66; petroleum in Gaspé (separate publication), 1865.

R. Bell.—Map of Gaspé in connection with the above (separate publication), 1865.

A. R. C. Selwyn.—Observations on gold fields, 1870-71.

J. F. Torrance.—On apatite in Ottawa County, 1882-84.

G. Broome.—On phosphate of lime and mica found in North and South Burgess, 1870-71.

H. G. Vennor.—Plan of Dalhousie iron mine, 1872-73; explorations in Frontenac, Leeds and Lanark counties, 1873-74; plumbago and apatite in Templeton, Portland and Ottawa counties, 1873-74; explorations in Renfrew, Pontiac and Ottawa counties, with additional notes on iron, apatite, and plumbago in Ottawa County, 1876-77.

C. W. Willimot.—On mines in Quebec, 1880-82.

Anonymously Catalogued.—Localities of copper ores in the Silurian of Lower Canada, 1858; on copper localities, 1863-66; notes on the gold region of Eastern Canada (reprint of various reports from 1843 to 1863—separate publications), 1864; map of North Burgess showing the positions of apatite openings, 1876-77; map showing phosphate of lime in Ottawa County, 1876-77.

ONTARIO.

Sir W. Logan.—On the geology and economic minerals of Lake Superior, 1846-7; on various economic minerals, and on the Industrial Exhibition of 1851, 1851-2; on the Ramsay lead mine and the Acton copper mine, and miscellaneous economic minerals, 1858.

T. S. Hunt.—On the Goderich salt region, 1866-9; on the gold region of the County of Hastings (jointly with A. Michel—separate publication) 1867; locations of copper ores in the Huronian rocks of Mississagui river, 1858; on the Goderich salt region (reprinted from the Transactions of the Canadian Institute of Mining Engineers, Vol. V) 1876-7.

H. G. Vennor.—On the geology of portions of Hastings, Peterborough and Frontenac counties, Ontario, with geological map, 1866-9. (Vicinity of Belleville).

Marmora gold mines, 1871-2; notes on economic minerals of Ontario, 1874-5.

T. McFarlane.—On the geology and economic minerals of portions of the County of Hastings, 1863-6; Laurentian, Huronian and upper copper bearing works of Lake Superior; with an appendix on the rocks and enopiferous beds of Portage Lake, Michigan, 1863-6.

HUDSON BAY AND LABRADOR.

R. Bell, Professor Dittmar.—Analysis of waters from Hayes and Nelson rivers, 1878-79.

MANITOBA.

B. J. Harrington.—Brick clay from Fort Garry, 1872-73.

G. C. Hoffman.—On lignites, 1873-74.

NORTH-WEST TERRITORY.

R. W. Ellis.—Borings for coal, 1875-76.

A. R. C. Selwyn.—Borings for coal on Souris R, 1879-80.

G. M. Dawson.—On coal seams of Bow and

Belly river district, 1880-82; general remarks on coals and lignites, 1880-82; geology of Bow and Belly rivers with special reference to coal (separate publication), 1882; map of coals and lignites Bow and Belly river, 1880-82.

G. C. Hoffman.—Analysis of coals and lignites, 1882-84.

BRITISH COLUMBIA.

J. Richardson.—On the coal fields of the east coast of Vancouver Island with map, 1871-72; the same including Queen Charlotte Islands with map, 1872-73; report on the coal fields of Nanaimo, Comox, Cowichan, Burrard Inlet, and Lovke with general map, 1876-77.

T. S. Hunt.—Analysis of Richardson's coals from Vancouver Island, 1871-72.

B. J. Harrington.—On (Richardson's) coals from the west coast, 1872-73; gold, silver, &c., 1874-75 and 1876-77.

G. M. Dawson.—General notes on mines and minerals of economic value in British Columbia, 1876-77; same with additions (separate report), 1883.

C. G. Hoffman.—Gold and silver assays, 1875 to 1885.

A. Bowman.—On Cariboo gold region, with general map; also sundry districts with detail maps (in hand).

MATTER IN GEOLOGICAL REPORTS.

Not catalogued as individual reports but occupying a portion of almost every geological report issued by the survey since its organization, is the consideration of all economic minerals encountered in the area examined. An index to those would be furnished by a similar classification of the physiographical material in subdivision 1; though it is not difficult to check off any desired portion or locality from the general list of publications of the Survey, if one had time to read over the 300 to 400 titles.

POPULAR AND PRACTICAL.

The museum has a wonderful faculty of drawing visitors. Mr. Burke, the doorkeeper, who keeps a visitors record, informs me that the yearly average is not less than 14,000; monthly, 1,000; and daily in fair weather not less than 40.

They seem to find something that interests them. What is it? The museum is not so instructive in some respects as are the magnificent Agassiz and Redpath museums. When one knows how imperfectly the majority comprehend what the Geological Survey Museum really is, or grasp the idea of how it may be utilized in a practical way for useful or business purposes, the curious fact would seem to require explanation.

It is observed that the objects on exhibition are all native, and that the animal, vegetable, and mineral worlds in their several departments are all represented. An inkling at once asserts itself that here is accumulated a wonderful store of facts lying at the foundation of every industry in the land. No one man's travels could have won them. No single fortune could

have done it, for the Geological Survey has cost, in the 25 years preceding confederation, \$375,000, and in the 20 years since confederation, \$1,000,000. Has it not been a good investment? What has been the "idea" of so large an investment? For no one calls it an extravagance.

CONCEPTION OF THE MUSEUM.

An intelligent handling of ones resources is undoubtedly the first consideration in every business.

The Government performs many functions which it is created or called on to perform. It leaves all others to be taken hold of by individuals. It gives attention by preference to those things which enable the people to help themselves. Foremost among these is education—placing in reach of every one the necessary information to handle his resources and powers effectively.

The National Museum is *all the provinces in miniature*. Its object is to place the necessary knowledge and facts regarding the Dominion and its resources, with their surrounding and controlling natural conditions, conveniently within the reach of matured men, and legislators who are commissioned to attend to their interests. Without such knowledge collected and presented conveniently to their hand, they would be compelled to skirmish individually and unaided in search thereof, just as the child would have to do without the advantages of an education.

ITS GROWTH AND "MANIFEST DESTINY."

Here is an institution occupying a three story stone block at Ottawa (since many years forming a department under the direction of the Minister of Interior) which has had a continuous active existence since A.D. 1843. Is it possible that what I have written in regard to it, and the matter it covers, should be read in these columns by many intelligent people not strangers to the museum with something like the freshness of news? The publications here referred to in the briefest manner possible, are more fully described in the price list of publications of the Geological Survey (to be had gratis on application), and are sold approximately at cost, a nominal figure when the publication is separate. This is now the case with all reports and maps issued, though they are annually bound together into volumes, for libraries and reference.

Has the generation of Wm. E. Logan, of John A. McDonald and of J. W. Dawson, whose energies have been those of the Dominion in its youth, done well in presenting this foundation to the active men who are to pilot the destinies of the Dominion henceforward?

The mining exhibit only faintly indicates the far greater wealth of the museum in physiographic and biological material tributary to agriculture, and sundry arts and industries too numerous to mention. Now as it is the busi-

ness of every one to look out for himself, and presumably of the statesman also in his public not less than in his individual capacity, is it worth his while, on behalf of his constituents, to consider well for a moment any thought which, looking forward to the proper destinies of the Canada of the next generation, can build up within our means the noble conception of a national museum?

One of the functions that has been acceptably performed by the Geological Survey for years has been the supplying and aiding in building up of local and provincial museums. Subterranean regions in charge of Mr. Willmot, devoted to this requirement, are seldom seen or heard of by the visitor. Several of the provinces, having special local interests, have inaugurated provincial geological surveys, supplementary to those of the Dominion, and commenced local museums of their own; the good policy of which is apparent.

Canada has its *central* mineral belt, the copper, silver, gold and iron belts of the Lake Superior region extending northward, and Drs. Selwyn and Bell think repeating itself along the coast of Hudson's Bay. It has the *cordilleran* belt with all the mineral wealth that term implies in North and South America. It has also its *appalachian* gold belt, which is interesting on account of the reported richness of some of its ledges; and *sundry coal and iron regions*, which justify us in saying her capabilities of sustaining even large populations in unthought of "deserts," may be far better than we have imagined. If so her rigorous climate, during a portion of the year, may turn out to be an advantage rather than a drawback; and the aspect of probable national developments is materially improved.

A. B.

Latest English Quotations.

The latest quotation for Canadian phosphate is eleven pence three farthings to one shilling per unit, with a rise. At the latter figures it will net to shippers over \$19 per ton in Montreal, on a basis of a dollar and a half for ocean freight.

MINERAL PHOSPHATES.—English buyers have been enquiring for Canadian, but no large sales have been made since our last. Owing to low steam freights the price of South Carolina Phosphate has fallen still further, and it is reported that 7½d. has been accepted for some large cargoes. Ground Somme Phosphate has been in active request, and Raisers are as yet not prepared for the demand. The lower qualities, 65 to 70 per cent., and 60 to 65 per cent., are also in request, but principally to Continental consumers. Belgian.—The higher qualities of this material are suffering from the competition of Somme, and are offering relatively cheaply. 40 to 45 per cent. can still be bought

for forward delivery at tempting prices, and a fair business has been done. Cambridge and Bedford Coprolites are quoted respectively at 42s. f.o.r., or Ground at 50s. in buyer's bags, or 52s. in lent bags, f.o.r., and the latter at 26s., f.o.r., or 31s. 6d., f.o.b., Thames.

OTTY LAKE MINES.—This property lies mainly in the 7th and 8th concessions of North Burgess, Ont., and extends for upwards of two miles along the north shore of Otty Lake. It is one of the few properties in Ontario where any considerable amount of phosphate has been profitably mined by hand labor, and upon its acquisition last fall by the Anglo-Canadian Phosphate Company, (Limited) it was determined to try the experiment of working it with machinery. During the winter, in spite of the inclement weather and heavy snow falls, quite a mining village has been created and plant has been erected, consisting of an eighty horse-power Return Tubular boiler, a seven drill Ingersoll air compressor, rock drills, double cylinder hoists, Knowles and Worthington pumps, and all needed accessories. Work was fully started on one seam in the latter part of March, and in nine days 117 tons of high class phosphate were mined from one pit, the total number of men employed on the property being 33, only two-thirds of these being engaged in mining. The April thaw caused a discontinuance of the work to some extent, but two pits are now in operation with the machine drills, and a third is being fitted with one of the Montreal Steam Crane Company's steam cranes and a Knowles pump. This seam contains a body of pure phosphate six feet wide and is increasing in width as it deepens. The seams in this district are not often as wide as some of the deposits found in the Lievres river district, but they are more continuous. One of the seams now being worked has been opened on the surface at intervals for half a mile, and another has been proved to extend fully a mile. The seams vary in width from one foot to seven feet. One difficulty in the past in the prosecution of this industry has been that persons, working one seam by hand with insufficient capital, abandoned the work whenever the inevitable pinches of the seam occurred, although an expansion might be considered certain to occur at a little distance. It is believed that by working several seams in a large way an average result will be obtained that will yield good returns. The company owns its own teams and is hauling the phosphate over six miles of good roads to the Canadian Pacific Railway at Perth, whence it is brought to the ships side at Montreal. In winter the hauling is only three miles across the lake to the Rideau Canal where barges can load for Montreal.

The Otty Lake Mines are in charge of R. A. F. Penrose, jr., Ph.D., (Harvard) a highly educated chemist and mineralogist, who has devoted some years to the special study of phosphates. The result of his researches is now being published by the United States Government, and will be of much interest to Canadian miners. Dr. Penrose is making experiments upon the separation of the impurities from the apatite, and the company expect to erect grinding mills and supply the phosphate in a pulverized condition.

On account of the very high water there has been very little ore shipped from the Ottawa district as yet. The river has risen three feet higher than ever before known at Buckingham, and most of the phosphate piled upon the bank has been submerged.

The output from the various districts continues to be most satisfactory.

A meeting of the directors of the North Star Mining Company was held at Montreal on 17th inst. It has been decided to continue the sinking of their main shaft, which, at present, has attained a depth of some 550 feet, and is showing very good ore at the bottom. It is calculated that not less than 3,000 tons of 80% ore is now in sight. Mr. Charles Kyte, of New York, Secretary of the Company says that he is much pleased with the general outlook for the season.

The High Rock output for last month figures close in the vicinity of 750 tons. The management expect to forward from seven to eight thousand tons of high grade ore. Their steamer and scows have been newly painted and present a very pleasing appearance on the river.

At the Little Rapids mines work is being pushed vigorously forward, the usual excellent output of high grade ore at comparatively small cost to the management continues, and a brisk season is anticipated. The new tramway which has been constructed as far as the river is rapidly nearing completion. The locomotive and cars have arrived and await the laying down of the rails which have been delayed in shipment on account of the increase in the tariff. The Superintendent, however, reports that everything will be ship-shape and in complete running order by 15th of next month, at the latest.

At the Emerald mines a very fine body of ore is in sight and operations are being conducted smoothly and vigorously. Shipments have been delayed by high water, but about 150 tons have been forwarded to Montreal. The management expect to ship close on 6,000 tons before the season terminates.

Although we have had no report this month from the Union Company's mines, the output is believed to be fully up to that of last month.

Everywhere throughout the Ottawa district much activity prevails and everyday the richness of the vast deposits becomes the more apparent. Even the most skeptical now admit that the phosphate industry has a great future in store for it and that at the present rate of progression it must soon equal that of lumbering. Under existing management the large majority of the mines are being most profitably conducted, while with the new and improved mining machinery which has been generally adopted and the increased facilities that have been made and are daily being added, managers will be enabled this summer to deliver the mineral at point of shipment to the best possible advantage.

As is well known, very large deposits of clear green and otherwise colored apatite occur in Canada from which very large quantities are annually taken to be crushed and manufactured in superphosphates for agricultural purposes. Such deposits also occur in Norway, where they have been studied by Professors Brogger and Reusch, who declared them to be of eruptive origin. Dr. Harrington, after showing that they occur in rocks of a similar nature, though unlike in detail, shows that there is abundant reason for considering that they are not eruptive rocks, and thinks that they were gathered by and crystallized from solutions. It may be recalled in this connec-

tion that M. Daubree made apatite in a closed tube by causing a volatile phosphorus compound to act upon hot limestone, and he thinks that some such deposits may have been formed by sublimation. The opinion of Dr. Harrington is sustained by the previously formed opinion of Dr. Hunt, and it will be seen that every possible mode of origin has to-day weighty opinion in its favor. But argument of such questions is progress, and is a long step toward conclusion, and these studies have contributed much to our knowledge of these deposits. Dr. Harrington describes immense crystals of apatite a foot or more in diameter and several feet long.

A process has been patented in Germany for the manufacture of precipitated phosphates from any kind of the ordinary crude rock. It is described as follows:—

"The rough material being first reduced to a very fine powder, is treated with just sufficient sulphuric acid to transform the carbonate and any free lime into sulphate. The mass is then subjected to the action of aqueous sulphurous acid, which dissolves only the tri-calcium phosphate and leaves the other constituents as a sediment. The clear liquid is decanted and subjected to a gentle heat; sulphurous acid is given off and reabsorbed in water—by means of a simple mechanical device—the phosphate itself being precipitated, washed, dried, and passed through a disintegrator. The preliminary treatment prevents the combination of the carbonate or free lime which would otherwise take place with the sulphurous acid, and averts the formation of a mixture of calcium sulphite in the final product."

"Tri-sodium phosphate" writes our esteemed contemporary, the *Engineering and Mining Journal*, "is being extensively brought to notice by the Keystone Chemical Company of Philadelphia, as a scale preventative. As is well known, the scale-forming matter in water, consists chiefly of lime sulphate, and carbonate, and magnesia carbonate, and hydrate, which are thrown out of solution by evaporation, and, falling as a dense crystalline precipitate, burn on to the iron in thick hard scales. These scales are very bad conductors of heat: a scale $\frac{1}{16}$ of an inch thick requires the use of 15 per cent. more fuel, $\frac{1}{4}$ of an inch, of 60 per cent more, while if it reaches a thickness of $\frac{1}{2}$ inch, the fuel must be increased by 150 per cent., and so on. It is hence apparent that to all manufacturers and all users of steam, any method of preventing this incrustation is a great desideratum. The use of tri-sodium phosphate for this purpose, has hitherto given the most undoubted proofs of its value. Nearly all the other scale removers in the market depend on their power of dissolving these lime and magnesia salts, and it is reasonable to conclude that if they will dissolve such a refractory substance as boiler scale, they will also attack boiler iron. This attack may be, and often is, gradual and slow; but it is none the less certain, though insidious. That tannic acid is destructive to boilers we have a practical proof in such peaty waters as are found in Florida, where the tannic acid formed in the water from the decayed vegetable matter actually corrodes the boilers to such an extent that in many cases copper tubes have been substituted for iron. Caustic soda is certainly effective in some cases, though the seams, rivets, and boiler shell, suffer badly from its solvent power, its affinity for sulphur causing it to eat out minute pin holes in the metal. Unlike any of these agents, the efficacy of tri-sodium phosphate is due to its faculty of decomposing the sulphates, and carbonates of lime, and magnesia, and forming in their stead, lime and magnesia phosphates, and soluble sulphate, and carbonate of soda. The following equation will give a general idea of the reaction induced:

The solid lime and magnesia phosphates are not dense, crystalline precipitates like the sulphates and carbonates, of which they take the place, but are light and flocculent, remaining equally distributed throughout the water as long as it is in ebullition and only settling down when the water is perfectly quiescent. Even when this precipitate does settle, it is in such soft, gelatinous condition that it can not burn on to the iron unless the water is first evaporated quite away; an impossible condition. Tri-sodium phosphate reacts equally well on metallic salts, such as copper and iron sulphates and carbonates, precipitating the copper and iron as phosphites, and leaving sulphate and carbonate of soda in solution. In cases where free acid is present in the water, as tannic acid in Florida, or sulphuric acid in the drainage of many mines, it will be neutralized by the alkaline tri-sodium phosphate, and the water thus be rendered harmless. Lastly, as tri-sodium phosphate does not itself act deleteriously upon iron, no ill effects beyond the waste of the substance will follow its excessive use.

Nova Scotia.

The latest brick brought in from the Moos-River Gold Mines weighs 76.8½ ozs., and is the result of crushing 58 tons of quartz.

During last year Mr. Tonquoy worked several leads on his property, among which might be mentioned the North, Little North, and Copper Lead. The South Lead was opened for about 60 feet. On the Copper Lead a new shaft was sunk, and about 70 feet opened. At present about 12 men find employment at the mine.

The following comparative statement showing the mineral production of the Province for the year 1886 is given in the annual report of the Inspector of Mines:—

	1885.	1886.
Gold.....Ounces....	22,203	23,362
Iron Ore.....Tons.....	48,129	44,388
Manganese Ore....."	353½	427
Barytes....."	300	230
*Antimony....."	758	645
Coal raised....."	1,352,205	1,502,611
*Gypsum....."	87,644	123,753
Building Stone....."	3,827	8,000
Coke made....."	30,185	31,604
Limestone....."	16,429	20,265
Grindstones, &c....."	2,208	1,600
*Moulding Sand....."	200
*Amount exported.		

Mr. J. E. Hardman, of Oldham, has recently sunk a shaft on his property to the depth of 230 feet, and is now working on a lead which, in some places, is 5 feet in width. So far the quartz is said to have yielded gold at the rate of 10 penny-weights to the ton, and constant employment is given to 28 men.

Quebec.

Prospectors in the Rocher Fendu District have brought in some capital specimens of gold quartz, galena, and white marble. The height of the water, however, prevented these parties from prosecuting their researches sufficiently to ascertain whether these minerals can be obtained in paying quantities or not.

It is reported that a half-breed made a discovery of gold deposit in the vicinity of Golden Lake, Black River, last winter, and has shown many varied and rich specimens of gold rock, but he will not show the location of his find without being paid a large sum of money. The specimens have been submitted to an analysis, and have been found to contain gold in large quantities.

The discovery of a valuable deposit of lead is announced in the Township of Waltham, Pontiac County.

The Asbestos Mines are in active operation and the present prospects indicate an increased output for the year. The late dry weather has been suitable for this class of work and operations have been pushed ahead vigorously.

About 50 hands are presently employed at the Anglo-Canadian Company's Mine, and the management are taking out between three and four tons of asbestos per day. They are at present sinking on what is called the Emelie pit from the bottom of which ore of a very superior quality is being taken out.

The Scottish Canadian Company are still constructing buildings and adding machinery, but we understand that at present they are not taking out much asbestos.

The Thetford Mines are all in operation and running about as usual.

At Danville the Jeffrey Mine is being operated upon a small scale, but with what results has not been ascertained.

Ontario.

The Queen Gold and Silver Mining and Milling Company has been formed at St. Paul with a capital stock of \$1,500,000. One hundred thousand shares of the capital stock, amounting to \$500,000, is to be sold, and the proceeds used in developing the property of the corporation at Whitefish Lake, Thunder Bay District. Incorporators:—Henry S. Sibley, J. A. Boak, C. G. Kimball, J. H. Hullsiek, J. Q. Hass, A. C. Ramsden, St. Paul; A. H. Truax, Hastings. Officers:—Henry S. Sibley, President; C. G. Kimball, Vice-President; J. A. Boak, Secretary; J. Q. Hass, Treasurer.

A meeting of the directors of the Kingston and Pembroke Mining Company was held at Kingston, on Monday, 23rd inst. The company estimate that 100,000 tons of ore will be shipped this year from the various mines along the line of the Kingston & Pembroke Railway.

The *Nipissing Times* announces that a valuable deposit of gold has been made in the neighbourhood of Lake Tomogaming, about 16 miles south of the Ottawa River. An assay of some of the specimens taken from the holes uncovered is said to average about \$70 in gold to the ton. The deposit is owned by Mr. P. A. Ferguson, of Mattawa, and Mr. John Caverhill, of Montreal, who propose developing it next month.

PORT ARTHUR DISTRICT.

Reduction works are to be put in at the Crown Point Mine.

Arrangements have been made for the further development of the Z-nith zinc mine some 10 miles north of Nipigon Bay.

It is expected that during the summer efforts will be made to open up some of the iron and galena deposits in the neighbourhood.

Messrs McKellar Bros. have announced their intention of developing the vein at 5 B. Silver Prospect, near Trout Bay.

The *Miner* states that McKellar's Island will again be worked this spring for the spar which the American market requires to "improve" paints. Men have already gone out to Pie Island to fix up the houses of the men, as it is considered cheaper to fix the houses up there and take the men back and forth to McKellar's Island than either remove the houses or build new.

A meeting of the Keevatin Mining Company was held recently in the office of the Secretary, Mr. L. McMeans. Mr. J. W. Harris occupied the chair. The object of the meeting was to consider an offer submitted regarding the purchase of the mine. Several well known mining men are preparing to develop the mine, and more activity than has characterized mining operations lately is anticipated in the Lake of the Woods region.

Mr. O. Dounais, the discoverer of the Silver Mountain and Rabbit Mountain mines near Port Arthur, is reported to have purchased a mining claim in this district for \$10,000.

British Columbia.

Mr. G. Henderson, Superintendent of the Foster M. & M. Co.'s mines, has purchased one half of W. D. Pattern's claim at Nicola. A ten stamp mill has been ordered and arrangements are being made to actively push the working of the new concern.

A gentleman writing to Mr. H. B. Cameron, of Messrs. A. B. Gray & Co., from Granite Creek, says that an old Frenchman, named Pardee, has struck quartz about a mile from Granite city, on the east side of the Tullameen River. Pardee is an old prospector and has been working since last summer, feeling that rich quartz existed in the hills near the river. He was put down as a "crank" and no one would take notice of his statements. After he had satisfied his curiosity and made up his mind that his supposition was correct he induced two men to go with him, with the above result. The people in and about the creek are much excited and the country is staked off in claims nearly to Allison's. The Frenchman says that he is likely to make his fortune now, and as he has got the people worked up to his way of thinking he feels jubilant.

A sample of quartz recently taken from the Hixon Creek mines has assayed \$585 to the ton.

The Ashcroft correspondent to the *Calgary Tribune* says: "The developments of the Hixon Creek Mine reveal an immense body of ore, the west wall of which was reached 23 feet from the shaft. Forty-seven feet of a cross-cut failed so far to locate the east wall and the ore looks good the entire width. Stock in this property has advanced three hundred per cent. and is still eagerly sought after. Some difficulty is being experienced in getting men, as most men coming to this country go straight to the coast instead of looking about in the interior.

The Island Mountain, the B. C. M. & M. and the Hixon Creek, all quartz companies, have made application to participate in the assistance provided by the guarantee clauses of the Act of last session.

The stamps at the Foster Milling and Mining Company's mines have commenced crushing.

The latest strike at the Foster Company's Mine is reported to be an exceedingly rich deposit of black sulphurets assaying \$136 in gold and \$29 in silver to the ton.

The machinery for the Skirk Mining and Smelting Company, under the management of Mr. G. B. Wright, is being placed in position and will soon be in active operation. The engine is one of Ames's celebrated 30 horsepower, manufactured at Oswego, N. Y.

A local exchange announces that "two mining superintendents from California and Nevada, who have just visited the Nicola mines, report very favourably on the prospects of the leads examined. The gentlemen are Messrs. Henderson and Probert, and the former has bought an interest in the Patterson mine; the latter will have an interest in an English syndicate that is expected to purchase the Nicola Mining Company's claim. A ton of low grade ore will be forwarded immediately from the mines to San Francisco to be further tested, and to supply the means of deciding what kind of machinery is most suitable for reducing the ores and working the mines. The machinery will be on the ground at an early date, and it is expected that it will be at work during the latter part of the summer. Two years work has been already done on these claims, and there are 600 tons of good ore now on the surface, but no ore has yet been realized on or reduced. It is probable that when the machinery at these mines is once in full swing that a considerable population will be attracted to the locality of Nicola; and as gold, silver, copper and other metals abound in the neighbourhood the prospects are bright in variety as well as richness. The Nicola mines, thirty miles by waggon-road from Kamloops, are situated near the Nicola River, which gives abundant water for continuous working and washing."

United States.

The quarterly report of the Plymouth Consolidated Gold Mining Company, ending 1st April, 1887, shews Gold Bullion produced as follows:—

January, 1887.....	\$62,350.49
February, 1887.....	60,683.75
March, 1887.....	59,296.45

Total product for three months, 1887.....	\$182,330.70
Operating expenses for same period.....	66,962.59

Profit.....	\$115,368.11
Cash on hand, January 1st, 1887....	81,079.89

Amount applicable to Dividends....	\$196,448.00
Paid dividends for quarter, No. 44 to 46, \$25,000 each.....	75,000.00

Surplus, April 1st, 1887....\$121,448.00

The Canadian Anthracite Coal Co.

LIMITED.

Miners & Shippers of Coal.

McLEOD STEWART, Pres., OTTAWA, CANADA.	J. G. THORP, Vice-Prest. EAU CLAIRE, WIS.
A. PUGH, General Manager, ST. PAUL, MINN.	W. B. SCARTH, Secretary, WINNIPEG, MAN.
O. H. INGRAM, Treasurer, EAU CLAIRE, WIS.	

Mines at Anthracite,

N. W. T., CANADA. v-1-1y

The Royal Society of Canada.

Through the courtesy of Dr. Robert Bell we are enabled to furnish the following list of papers on geology, mineralogy, and other subjects of interest to the readers of the *Review*, to be submitted at the meetings of the Royal Society of Canada, presently in session at Ottawa. Judging from abstracts of the various subjects made by Dr. Bell, all these are full of scientific interest, and when published in the *Transactions* of the Society many of them will be of much practical value to the general public. The Session will close on Saturday, 23rd instant. Mayor Stewart will entertain the members at a garden party to be given at his residence on Friday afternoon, the 27th inst. The number of papers promised and already submitted is greatly in excess of that of former years.

A Comparison of the Flora of Hudson's Straits and the Arctic Regions of America. By Prof. George Lawson, Ph.D., L.L.D.

Additional Notes on the Geology of Aroostook County, Maine. By Prof. L. M. Bailey, M.A., Ph.D.

(A Geological Subject.) By Rev. J. C. K. Laflamme, D.D., M.A.

The Erosive Power of Glaciers, as seen in Norway. By Prof. J. W. Spencer, M.A., Ph.D., F.G.S., Professor of Geology in the State University of Missouri (formerly of the Geological Survey of Canada.)

The Correlation of the Animikie and Huronian Series of Rocks. By Peter Mackellar, Esq., (formerly of the Geological Survey of Canada.)

The Classification of the Trilobites. By Prof. E. J. Chapman, Ph.D., L.L.D.

The Diurnal Motion of the Earth in its Relation to Geological Phenomena. By W. A. Asher, D.T.S. (meteorological observer, Quebec, and delegate from the Literary and Historical Society of Quebec.)

The Economic Minerals of Nova Scotia. By Edwin Gilpin, M.A., F.G.S.

The Gold Bearing Rocks of British Columbia. By Amos Bowman, Esq., (of the Geological Survey of Canada.)

The Utica Formation in Canada. By Henry M. Ami, M.A., F.G.S.

The Classification of Rocks. By Thomas Macfarlane, M.E.

The Geography and Geology of Baffin Land. By Dr. Franz Boas (arctic explorer and editor of *Science*).

Theory of the Movement of Land Ice. By J. W. Spencer, M.A. Ph.D., Professor of Geology in the State University of Missouri.

Petography of the Drift of Central Ontario. By Dr. Coleman, Victoria University.

Papers of unusual interest on kindred subjects will be submitted by Dr. Bell and others. In our next issue we hope to be able to publish abstracts from such papers as are of more immediate concern to the mining public.

A new publication on Algoma West will be submitted to the public early next month. The mines, scenery and industrial resources of the district are said to be special features of the work which is edited by Mr. W. Roland, C.E.

The Great Ice Age and Subsequent Formations at Ottawa, Ontario.

By H. M. Ami.

Of the Ottawa Field Naturalists' Club.

This portion of the American Continent, which, during the earlier palæozoic period had alternatively been submerged and elevated, remained in this latter state a long period of time, during which denuding agencies, such as atmospheric erosion, rain and other solvents carried away a great deal of material. This is a lapse of time, which, in other parts of Canada and elsewhere, is marked by a regular ascending series of newer formations deposited for the most part beneath the level of the then existing oceans, a period embracing within itself the whole of the Silurian and Devonian systems together with the Carboniferous age of the coal measures: the Palæozoic age thus ended, Mesozoic times came in and the Triassic, Jurassic and Cretaceous systems followed, overlying which all the Jaramie and Tertiaries were laid, all of which are entirely absent in our district marking a great unconformity between the Glacial deposits and the Hudson River rocks about Ottawa.

The *Glacial Epoch* or the *Great Ice Age*, then, is the first of the series of Post Tertiary times with which we have to deal, as it rests immediately upon, though with discordance of stratification (if that term may be employed here), and overlies the Cambro-Silurian and older formations in this district. Just previous to this period of glaciation, and whilst it lasted, there must have taken place a great elevation in this part of the North American continent, so that an extreme Alpine or Arctic climate was the natural result. Nor was this part of America the only one which enjoyed this particular state of affairs, but throughout the greater portion of North America as far west as the Great Missouri Coteau, in Europe and other continents, evidence of extreme cold, the result of great elevation, has, through the labours of leading geologists, been ascertained beyond doubt. Prof. Favre, of Geneva, whose admirable researches in Alpine geology have made him so famous the world over, in the "*Résumé*" of his "*Geological Researches in Savoie and the neighbourhood of Mt. Blanc*"—points out clearly what was the origin of the glacial epoch in that part of Europe. "The amount of moisture or humidity," he says, "with which the atmosphere of Europe was filled on account of the elevation of land subsequent to the deposition of the tertiary deposits—the cooling effect of the neighbouring mountains, then more elevated than now-a-days—together with many other causes, led to a reduction in the temperature of the atmosphere resulting in an abundant precipitation of snow on the leading peaks of the region." So in Canada, and in the Ottawa district: a great reduction in the temperature followed the great elevation, and immense quantities of snow, ice and water followed and glaciers were formed all over the district—a vast *mer-de-glace* covered this portion of Canada whose height above the ocean level of that period was very great. These glaciers, like modern ones, were characterized by many interesting particulars which a study of the latter can afford. The number, direction, movements, thickness, erosive or denuding power and the constituent parts of a glacier or a system of glaciers are questions full of interest. It has been ascertained that over four hundred glaciers can be seen in the central portion of the Alps, from Mount Blanc to the Tyrol, some of which are only three miles in length, whilst others exceed twenty miles from head to foot or from the point of origin to

the snout. There is abundant evidence to show that the number of glaciers which must have existed here about Ottawa is very considerable indeed, whilst the number of them in the whole of Canada and the United States must have been very great. Many of them, and perhaps the greater number, were subordinate or smaller ones and may, at length, have been absorbed in and formed part of "a great glacier." The direction in which they moved depended of course on the nature of the district, its physical or orographical character. The general trend of the great *mer-de-glace* in Canada during this epoch has been ascertained to be approximately N. E. and S. W. The direction of some of the glaciers as obtained from the striations or grooves on the rocks about Ottawa show that in some cases they travelled almost due east and west, as may be seen along Park Avenue, on Nicholas street and in other parts of the city, at other times they appear at a considerable angle to this direction, bearing almost due north and south, as at Buckingham on the Lièvre River. Regarding their movements, the speed with which glaciers travel, we consult Agassiz and find that he obtained the following results in 1841 and 1842 on some of the Aar glaciers:—

	ANNUAL MOTION.
I. FINSTER AAR—	
{ Stake near centre of glacier... 269 feet.	
{ " side " ... 160 "	
II. LAUTER AAR—	
{ Stake nearest centre of glacier... 245 "	
{ " side " ... 124 "	

whilst at Chamonix the ice near the shore of the *mer-de-glace* was found to move as follows, from June 29th to June 8th of the following year:

From June 29 to Sept. 28...	132 feet.
" Sept. 28 " Dec. 28...	70 "
" Dec. 12 " Feb. 17...	76 "
" Feb. 17 " April 4...	66 "
" April 4 " June 8...	88 "

Total (in less than one year), 432 feet

This would average over five hundred feet or about one-tenth of a mile in twelve months. The rapidity in the motion of a glacier, of course, depends upon the nature of the obstacles to be surmounted, as well as to a great extent upon the time or month of the year, whilst different portions of the same glacier move at a different rate. A glacier which descends into a valley below or discharges itself into a sea or arm of an ocean does not necessarily lose any of its length, for whilst its snout is being melted and carried away to warmer portions, the head or initial point is ever receiving additional snow and ice to supply it constantly, and only a subsidence of the continent could produce a change in the climate of such an ice bound district.

We have no data existing here or traces left by means of which we can calculate the rate of motion of the glaciers about Ottawa during the great ice age, suffice it to say that as in the case of modern glaciers so it must have been in the case of the old Ottawa glaciers, their rate of travelling varied at different times in different circumstances. Then as to the thickness of the great ice-mass which had then invaded this district, that is a problem which to a great extent, has yet to be solved with us, nevertheless, let us examine the data at our disposal in reference to this interesting phenomenon. Taking the Ottawa Valley, in and around the city, as a very typical example of a valley of erosion with subordinate branches, we see that facing the river, there occurs a series of high "bluffs" or cliffs where the strata are clearly seen along

their sides to be throughout, nearly horizontal.* That these beds could not have been deposited in such a position is beyond question and goes without saying, so that the prolongation of them northward must at one time have existed. What was it then, which removed all these and to such a depth? This very question gives us a clue to one factor at least in the estimate of the powerful ice-mass which, coming from the West or W. N. W. struck down upon the shales and limestones of the formations here to be found. It also gives us data to estimate its thickness. The occurrence of *striate* rocks at the top of old Barrack Hill, where the Parliament Buildings now stand, show that as that cliff is one hundred and eighty-seven feet above the level of the river, and over two hundred feet above the level of the bed of the river, the mass must have been much over two hundred feet. Further, in order that a mass of ice or a glacier carrying boulders and detritus—*moraine profonde*—can groove and polish the rocks of a district to such an extent as was the case here, the superincumbent weight and attending pressures must have been enormous, and from what is known of present glaciers, whether in alpine or arctic regions, their thickness is very great. A fair estimate, we believe, of the thickness of the glacier or *mer-de-glace* extending over our city and its environs during the glacial epoch must have been very little short of one thousand feet, if indeed that number is not too small. The erosive or denuding force of glaciers has just been touched upon whilst a great deal might be said on the subject; for, when we take into consideration the millions of tons of material which has been transported away from even the small area about our city and examine the amount of cutting, abrading and ploughing which must have occurred, it is simply marvelous to know where it all went. You can hardly pick up a loose rock or boulder in the fields without seeing written upon it indubitable marks of scratching and grooving, which, along with millions of others were held firm in a mixture of cementing clay and sand (to a small extent) carried forward upon the floor of the glacier and one against the other, at times, to such an extent that all angularities and rough points are removed and the boulders left smooth and polished. The *striations*, *grooves* and *polished* surfaces of rocks which up to this date attest clearly to the fact of the existence of those glaciers, besides the boulders themselves, may be seen not only in the places already mentioned, but in numerous other localities, and they only await the student of Post Pliocene geology to afford the information they can readily give at the corner of Sussex and Rideau streets, where an interesting spot occurs.

The effect of these glaciers upon the softer *shaly strata* of our neighbourhood is clearly shown in such a deposit of the Utica shales as is met at Cumming's Bridge, on the Rideau River or at the corner of Maria and O'Connor streets, some 12 feet below the surface of the roadway. At these two places, whilst the shales of the Utica formation also occur *in situ* and undisturbed at a greater depth than is visible in either section, the uppermost measures of the section exposed and examined cannot certainly be said to be strictly *in situ* as the beds are tilted at every conceivable angle, crushed and broken. In the overlying glacial deposits are to be found some of the boulders which assisting in tilting and disturbing these once horizontal measures.

*There are but few exceptions to this, due to dislocations, faults and folds in the strata of purely local origin, but not of general significance in this problem.

There occur a vast number of faults and dislocations in the measures of the Trenton and other formations about Ottawa, great breaks, which at times, run more or less parallel to each other and were the result of great pressure brought to bear upon the beds in question. Whether these faults and breaks are due to disturbances which took place about the close of the Silurian Age, or at the introduction of the Devonian, when *Rigaud* and *Montreal* mountains and other similar volcanic or intrusive masses were ejected amidst great perturbation; or whether some of these faults were not in part due to the enormous pressure which the great ice-mass exerted upon the strata in later glacial times are questions which, though readily suggested by the phenomena examined, do not find so ready a solution. Having now examined the number, direction, movements, thickness and the erosive power of the glaciers during this Great Ice Age, having very cursorily glanced at the results which were effected in giving the country the general appearance which it possesses at the present day, there remains to find out what are the materials which were deposited and under what conditions they were deposited.

The masses of *boulders*, also termed "*boulder clay*," "*moraine profonde*," &c., unlike both the underlying older and overlying newer deposits are *not stratified*, i. e. they have no divisional planes of stratification or true bedding. Pebbles of various sizes and of every kind of rock in the district, usually rounded and smooth, held together or cemented by an argillaceous paste or clay with a certain admixture of arenaceous material derived from the more finely crushed *detritus* and *debris* at the bottom of the glacier, form the lowest division of our Post-Tertiary deposits. These "*boulder clays*," as they are appropriately termed, have a very large percentage of boulders in them, the finer material being scanty and in a finely-divided or comminuted state.

Such a deposit is one which "*land ice*" alone produces and one which resembles wonderfully the "*moraines profondes*" of the ancient Rhône glacier as they may be seen near the Western extremity of Lake Geneva (a mile and a-half below) and in the adjoining districts. In further corroboration of these boulder clays being due to land ice is the fact that none of the organisms which would be expected to characterize marine clays are present therein. The total absence of organic remains (so far as ascertained) in these glacial clays, coupled with the fact of their occurrence in abundance in the Leda clays above point clearly to a wide difference in the mode and condition of deposition of both, the one being laid at a great elevation above the sea level, the other below the level of an ocean or arm of a sea.

In examining the surface geology of Ottawa, one is struck with the diversity in the distribution and extent of this "*boulder clay formation*." In some places, the only indexes present which point to its existence at one time, are the striae and grooves over the bare rocks, such as they are exposed principally about Hull and Ottawa in the vicinity of the Grand River, whilst there are also numerous fields and tracts of country which exhibit that formation very clearly. In such *glacial* and *post-glacial* valleys and districts, from which the "*Leda clay*" and *Saxicava sand* and *overlying strata* have been removed by denudation, there occurs a large quantity of these boulders. Amongst these are no doubt included, at the present day, the erratics of all which were dropped by ice-bergs at a period subsequent to the great ice age, nevertheless the character of the fields where this formation is met is well known, and especially to the agriculturist. The Rideau River Valley,

of post-Tertiary Age, and very recent geologically speaking, presents numerous points of interest from its mouth at the falls in New Edinburgh to the Hog's Back. Nearly the whole of the Post-Tertiary formations were carried away by the once wide stream which flowed in that vicinity, and even the glacial clays suffered not a little, as the materials cementing the pebbles are to a great extent entirely wanting. The Rideau Rifle Range extends, for the most part, over this formation, whilst the southern portion of the range, as well as its northern limit (at the 600 yard buttes) are on the outskirts of the newer overlying marine clays. We have already spoken of *moraines*. These vary very much in extent and distribution just as the "*boulder clay*" or "*till*," as it is also sometime called, varies from next to nothing to twenty feet or more in thickness in different places, and are extensively developed about Ashburnham Hill, Gilmour's Mills, near the Hog's Back, etc., occupying its lower and regular position at the bottom of the Post-Tertiary series in Upper Town, Centre Town and Stewarton, cropping out in the rear of the City Hall, on the east side of the canal, ever keeping its normal position. It is very generally distributed thence in beds varying in thickness in the area included in a curve drawn from the New Militia Stores on the canal along Sussex street up to St. Patrick street then produced on to the bridges over the Rideau river, pretty nearly in a line with the curve which Sussex street there describes, and across to New Edinburgh through the Rideau Hall grounds to a small extent where these deposits thin out markedly, and continuing the line through Beechwood, in Gloucester, on in a south-easterly direction, we have a horse-shoe curve, in which are included vast accumulations of material left us by this Ice Period. But to come back to the *moraines*:—There are, besides these hard, coherent masses of "*boulder clay*," large aggregations of more or less uniform-sized boulders held very loosely together which form a prominent feature of the country. At Gilmour's Mills there is a good example of one of these whilst there has already been pointed in the "*Geology of Canada*," 1863—already cited—that a number of zones or belts of boulders cross the Ottawa at different places near the city, one of which a few miles below Ottawa produces a shoal on account of which the navigability of the river at this point became dangerous and obliged the Government to erect a lighthouse. These are what are termed "*morainic belts*," and are prominent features to consider.

There are a number of other particulars respecting which the detailed notes obtained from the excavations that have been carried on in our streets, though bearing immediately on this subject, cannot be included for the present.

Following this period of *great elevation* and of extreme cold there came a period of *submergence*. Nor must it be surmised that the subsidence which took place in this part of the country was necessarily effected in a short time; on the contrary, it must indeed have taken ages for the country to have come down even to the level to which it is at present—a height of some 215 feet above sea level at Ottawa. As the elevated ice-bound country was gradually subsiding, there came an amelioration in its climatic condition, and more temperate seasons ensued. The glaciers which at one time discharged their materials in valleys and on land—feeders to a regular system of glacial rivers both in the lowlands and in the mountain districts—now discharged these along the coast, and coast-ice and icebergs were soon at work as the sea was encroaching upon the land and depositing over the old beds of the

glaciers a series of sedimentary strata, with which there came also the life and organisms common to such *habitat*, so that the next period or formation with which we have to deal is one of marine origin, deposited in the still depths of an ocean or sea and containing the remains of animals common to that period in the earth's history. Meanwhile innumerable quantities of ice-bergs, carrying with them large blocks of rock and detritus—themselves portions of glaciers—were scattering their burden over the bed of this ocean or sea, as the warmer regions were reached, as at the present day, along the coasts of Labrador, Newfoundland, and adjacent districts, the icebergs detached from their northern fortresses sweep down towards the centre of the earth—no doubt to a great extent due to that transporting force developed in the rotation of the earth.

There are certain geologists, I believe, who would account for the *grooves*, *striations* and *furrows* in the hard rock masses below being formed, through the agency of *coast-ice* and *icebergs*. Whilst admitting the possibility of certain local and limited areas as capable of being effected by the agencies above mentioned, there is little doubt that they are together wholly inadequate to explain the phenomena of striated surfaces (see Prestvich) over such vast areas, as it is known that these surfaces extend, in some cases, for hundreds of miles.

But, of the sedimentary strata which, during this period of submergence, were being laid down over the remains of the glacial epoch the lowermost series consists of bluish gray clays of more or less plasticity and varying greatly in thickness in different parts of this region. There are a number of sections both *natural* and *artificial* which this district has afforded. Amongst the latter may be mentioned the Rideau Canal, which from the "*Basin*" to the "*Deep Cut*" "gives a very good idea of the thickness of these clays there. Then the hundreds of sections which the recent excavations carried on by the City Engineer have exhibited where in almost every instance, the clays may be seen in their normal position though in some cases they are totally absent. Then comes the brick-yards owned by the Messrs. O'Dell, Clark, Nicholson, Graham and others. In the first mentioned of these—Mr. O'Dell's—have been found remains of a fossil sponge, the *Tethea Loganii* of Dawson, together with *shells* and *foraminifera* and a bone sent to Prof. Cope for identification, all of which were communicated and presented to the writer through Mr. A. P. Low, B. App. Sc., of the Geological Survey of Canada. But whilst *artificial sections* are often more convenient in ascertaining the relative thickness of the different kinds of strata, nevertheless, the *natural sections* which are met with everywhere, enable us to obtain the geographical distributions, extent and thickness, sometimes with greater facility, as these sections are very numerous indeed. Along the left bank of the Rideau River, e. g., from the Hog's Back to the Falls, down the Ottawa as far as Green's Creek, and farther across the river in Hull Township as far as Ironsides, and above that towards New Chelsea. In Nepean and Gloucester Townships there are hosts of *natural sections*, where the "*Leda clay*" formation is well exposed—antiquaries the name implies, so-called on account of the prevalence of a small bivalve shell,—*Leda (Portlandia) arctica*, *Gray* which is, in its measures, quite commonly and it occurs everywhere exceedingly characteristic.

An interesting point about these clays and accompanying strata is the fact that they occur in many instances in the shape of "*terraces*" or

small plateaus following one another at different levels. Standing on Parliament Hill some of the more prominent 'terraces' may be clearly seen to the N. forming for a considerable distance an almost unbroken line of level stretching from east to west in the general trend of the Ottawa River. One of these occurs just above Ironsides, as many members of the Club have had occasion to notice, forming a general plateau of clay covered by a thin stratum of sand. These terraces point indubitably to a period of subsequent elevation which was characterized by oscillatory movements i. e. a period elevation which is not constant, during which periods of quiescence intervene. Such an elevation predicates the next period with which we are to deal; but before entering upon this latter, there are important results which must be noted with regard to the "Leda clay" formation. Imbedded within its measures are found a goodly number of interesting organic remains. Nearly all of them are of marine origin and consist in the remains of shells, insects, animals and even plants which will together, when all examined and determined, make not far from thirty distinct species.

With scarcely a single exception all of these species of shells and animals can be dredged up alive now-a-days either in the Gulf of St. Lawrence or along the Coasts of Labrador or Newfoundland, and even as far as Norway. Their mode of preservation is not an uninteresting fact to record, as it is peculiar even in different portions of the same formation. At Green's Creek, for example, on the Lièvre River, and in other localities likewise, both above and below our city, these places are noted for the peculiar nodules which are found included in the clays. By some such process as concretionary action can the agglomeration of finely divided particles of argillaceous rock be best accounted for organism, principally around some nucleolus whatever it be—a pebble perhaps as in some instances. Numerous remains of the *Nautal*, *Mallotus villosus* (Cuvier) occur in this manner whilst it more often happens that the nucleus is so small as to be invisible. These nodules have also yielded two other kinds of fish, the lump sucker and a sculpin found by Mr. Stewart recently, all these still living in the Gulf of St. Lawrence. Sir William Dawson has a beautiful collection of these nodules from Green's Creek, from which he has identified a large number of species of fossil plants, among which are twigs and bunches of the white cedar which is met with not unfrequently. Another mode of preservation of these fossils at Green's Creek is through the infiltration of a siliceous solution, so that shells are as the remains thoroughly silicified in this deposit as they are in the Black River formation at Paquette's Rapids, or in the Corniferous formation of Western Ontario, muriatic acid not affecting the shell in the least. Others are preserved with but little change from the character in which they were entombed whilst others appear as if they were live shells with the *epidermis* on and nicely preserved.

Of the other fossils which characterize this formation a great deal might be said, but passing over the important discoveries of seal remains made by Dr. Grant of Ottawa years ago, and noticing the feather or remains of birds which Lord Lorne obtained when on a collecting tour at Green's Creek, during the term of his administration in Canada, and merely mentioning the fact that a number of insects have been found there on different occasions by various persons, it will also suffice to mention that during the past season a large number of *Foraminifera* were collected. These are minute

microscopic, shell-like protozoa of very simple organization internally, but the shell itself or place of habitation of the animal is very elaborate, and in many cases beautifully ornamented. These organisms are flourishing in the abyssal depths of the ocean and thrive also along our shores whilst they abound in the Gulf of St. Lawrence, and to such extent that as the sounding lead of a steamer touches the bottom, it often brings up a number of these alive. Dr. G. M. Dawson, whose extensive researches in Post-Tertiary Geology have enabled him to give valuable information regarding the best mode of obtaining these very minute organisms from the clays and of working out the microscopic character of the deposits in question, has very kindly given the writer such hints as have proved of utmost value in this connection, so that by a series of percolations of a solution of clay and water, on sheets of blotting-paper or filter paper, a large number of specimens were obtained. The largest of these, and a common species in nearly all the collections from the Gulf and elsewhere, is *Polystomella crispa*, L. It also occurs here at Ottawa. Besides these forms there remains a great deal of material ready to be worked up and awaiting identification.

It has already been hinted that the "Leda clay" formation, laid down beneath the level of an ocean or sea which extended in this region as far west as the Bonaventure River (*loc. cit.*), was followed by a period of elevation. Whilst these clays were thus being deposited along the bottom of the sea, i. e., at some distance from the shores, the sands and gravels which usually mark the littoral deposits of an ocean were being deposited in this vicinity in regular order. They are arenaceous deposits in which distinct lines of stratification occur where both the sands and gravels overlie the clays everywhere, but their thickness varies considerably in different places. This uprising of the continent which exposed to view the former depths of the ocean, once begun has continued on, and there is no index to point out whether this elevation has, up to the present day, ceased. The sands and clays which were laid along the shores and bottom of the old Ottawa Sea, up as far as the Bonaventure River, are now some 500 feet above the mean tide level at Three Rivers, so that there must have been, at least, an elevation of 500 feet in this part of the American Continent in later Post-Tertiary times. These sands, to which the term "*Saxicavea Sand*" has been applied by Sir W. Dawson and others, are very generally distributed over the gravels, clays and older boulder glacial clays in this district. Sandy Hill received its name no doubt on account of the prevalence of this rock about that part of the city, although there is perhaps 15 or 20 times more clay on Sandy Hill than sand. Near the junction of the sands with the clays below and in places when the the gravels are not coarse, there are found several species of fossils, some of which have already been recorded in the Club's transactions. *Macoma Calcareea*, Chemist, *M. fragilis*, Fabr., *Natica affinis*, Guelin and others occur in these deposits, but as a rule they are nearly always destitute of fossils. As there must certainly have been many at one time their remains must have been decomposed and become obliterated. A peculiar seam one inch in thickness occurs near the corner of Waller and Rideau streets, and divides the Saxicavea sand into two parts. This bed consists for the most part of leaves of poplar and other trees, bits of grasses and sedges held together, but it is continuous only over a limited area. The upper portion of these sands is that with

which we have last to deal, and is included in that period which we call here the Human period, for in it do we find for the first time traces of the existence of human beings. The loam or surface soil, cultivated or not, that soil in which implements of stone are found associated with fragments of pottery, bones of deer, bear, beaver and other animals, points clearly to the fact that man of two distinct types has left his mark in these newer overlying beds. Previous to this, however, no records exist which show, that here in Canada, man came in these times except subsequent to the Glacial Epoch in the newer and present Historical age.

Nor is the economic aspect of the question, in reference to the use to which the materials which compose the Post-Tertiary deposits of this district can be put one of trifling importance whether in furnishing useful materials to railroad, commercial, agricultural, or other interests. For ballasting, road metal and the like, the Saxicavea Sands, gravels and Boulder Clay formations have been extensively used by the Canada Atlantic and Canadian Pacific Railway authorities throughout this district along their roads at Ottawa and its environs, whilst the sands themselves afford splendid material in the manufacture of mortar for building purposes and to such an extent it is that a good sand quarry is more remunerative than a gold mine. But whilst these substances are of incalculable value to man, the marine clays of the "Leda Clay" formation supply the brick and tile manufacturers with the material wherewith to turn out these useful building and other requisites and likewise afford an inexhaustible supply of the argillaceous substance necessary in the manufacture of Hydraulic cements, of which the Hull cement of this locality well-known to be a good slow-setting cement.

There are many good brick-yards in the vicinity which derive their material from the clays in question, and whilst, it is not deemed necessary to signal out any particular one, nevertheless, that of Mr. T. M. Clarke, of New Edinburgh is worthy of note, as from it, that gentleman turned out a large quantity of white brick of superior quality, by carefully inserting a certain percentage of the white earth taken from the marls overlying the saxicavea sands at Hemlock Lake, in McKay's Grove, and submitting it to successful process. Brick manufacturing is a most remunerative occupation, especially in such a growing place as Ottawa, where the supply can scarcely equal the demand and the materials are ready and at hand. Mr. Wright, the manufacturer of the Hull Cement, informs me that the marine clays which he uses are very well adapted indeed for the purpose intended, being almost equal to the mud or clays dug out of the Thames in England, for the manufacture of the "Portland and Roman Cements," so famous everywhere.

The manufacture of pottery is likewise an industry or art which flourished at Ottawa, but as the place where the works were situated was in as bad a position as possible for the purpose, the enterprise has ceased to be carried on. It cannot be denied however that there is 'money in it' for whomsoever undertakes this industry and takes up a proper location.

The plastic nature of certain strata in the lower portion of the Leda clays afford good substance for modelling purposes and has already been used to a certain extent in this direction.

There is a large percentage of *alumina* in these clay deposits, and when we think of the vast advantages which the metal *aluminium* presents over such substance as iron, copper, lead and zinc, it may not be amiss to look for-

ward to the time when a process will have been discovered which will enable its being manufactured from clays such as we have at our very doors. Nay, if I am rightly informed, a series of very successful experiments have been carried on by French chemists and others of late by means of which that metal can be produced, but at a cost which, at the present time, is too great so that this aluminium industry cannot compete with that of iron. Those who are familiar with the properties of this metal will clearly see what advantages the community would reap if aluminium could be manufactured cheaply and from the clays which are so abundantly distributed with us.

And to sum up the results thus obtained in the examination of the Post-Tertiary deposits of Ottawa and vicinity, an ideal vertical section, made to include the various measures which compose them is here given:—It is taken from an actual section in the excavations on Waller street, near the corner of Rideau with that street. The lowest beds met are those beds of 'Boulder clay' or 'till' forest on which overlie the glaciated surface of the Trenton formation (Cambro-Silurian) below. Their thickness does not exceed five feet and are immediately overlaid by marine clay with fossils, and at times present a loose boulder or erratic "Leda clay" which some floating iceberg dropped on its way to warmer climes. The 'boulder clay' points to a period of considerable elevation of this part of the American Continent, when land ice covered the whole of this region. These "Leda clay" deposits point to times of submergence when the Atlantic Ocean extended as far inland as here, and when the shores of this sea were the Laurentide Hills, to the north and to the south the Adirondacks—shores which would have presented to an observer had he been there in those days, a similar scene which the barren coast of Labrador does now-a-days. The thickness of the clays varies very much in different places, at this particular spot it is only one and a-half feet thick and is overlaid by a thin bed of gravel, in turn overlaid by two strata of dark and light coloured sand respectively, which are separated by the bed of plant-remains, one inch thick, already referred to. These sandy or arenaceous strata though deposited on the shore or margin of an ocean or sea, point clearly to a period of elevation, which period has been going on ever since, so that this part of the American Continent may safely be said to be rising yet, at least in Eastern Canada, and until we have actual proofs of a submergence going on, a depression along the coast or an encroachment of tidal and other oceanic phenomena on the land, we may rest safely with the happy thought that we are on the upward move.

[There is a vast deal upon which it has been impossible to touch in a paper of this kind. I have only skirted the shores of the captivating subject before us, I have only glanced at some of the problems which press themselves upon us in examining the parts in question, I have barely touched and just stepped upon the threshold of Post-Tertiary Geology, which, *par excellence*, will form one of the most important subjects for geologists in the future.]

Geological Surveys.

In our last issue we drew attention to the importance and great value of this branch of Government work, but limited space prevented us from going so far into the subject as we desired. Comparing the last eight years of the amount of this work done in Canada with that done by the United States Government, and in addition to that the work done by the separate

States in former years and at present. The areas of Canada and the United States to be examined with the means thus appropriated. In area, Canada is larger, while the expenditure is very much smaller, and is done wholly by the Dominion Government, the several provinces spending nothing under this branch of the service. The Dominion, therefore, has reason to be complimented on the good results of so small an expenditure when the field is so wide in area and object, embracing, as it does, Natural History, and a Museum which does Canada honour and is well worthy of being enlarged to provide for the growing importance and necessities of this branch, altogether an institution of the highest educational and economic value. It must be remembered that in the United States amount, a museum has not to be included. The knowledge and good which has resulted from Geological discovery, in a general sense, expanding, as it does, our knowledge of the true order and condition of the earth, increasing human happiness and therefore lessening misery, in aiding the thinkers among mankind to the true system of creation or progression in nature, in liberating and enlightening the race from "the darkness of dream-land." When such good results have followed this system of discovery it is incumbent on our legislators to enact the best laws in order to receive its full educational and economic reward or value. Canadian Geological Survey including

	Nat. History Museum.	Civil Govt. List.	Total.
1879..	\$52,933.97
1880..	52,127.32
1881..	65,791.36
1882..	64,720.60
1883..	62,328.34
1884..	60,000.00	\$30,504.00	\$90,504.00
1885..	60,408.97	31,967.33	92,376.30
1886..	78,557.69	35,936.03	114,493.72

Through the kindness of the Hon. J. W. Powell, director of the United States Geological Survey, we are enabled to give the following statistics of geological work done in the United States.

	U. S. Federal expenditure during the years		
Fiscal year.	General Appropriation	Special Approp. for Salaries.	Total.
1879-80..	\$100,000	\$6,000	\$106,000
1880-81..	150,000	6,000	156,000
1881-82..	150,000	6,000	156,000
1882-83..	222,000	34,940	256,940
1883-84..	304,700	39,940	344,640
1884-85..	453,700	35,340	489,040
1885-86..	467,700	35,540	503,240
1886-87..	467,700	35,540	503,240

The appropriation for the fiscal years 1887-88 is the same as for the present year.

The following is the work done by the several states independent of the above amounts:—

ALABAMA.

There is a state geological survey in progress under the direction of Dr. Eugene A. Smith University, Tuscaloosa County, Alabama. It is supported by an annual appropriation of five thousand dollars for the period of ten years, beginning with 1882.

ARKANSAS.

A geological survey of this state was made 25 or 30 years ago by Dr. David Dale Owen, whose reports were published in two volumes, dated 1858 and 1860, respectively. No further official geologic work has been done in the state; but within a few weeks a new state survey has been established, with Professor John C. Branner as state geologist. The terms of the law establishing the survey are not fully known; but the salary of the state geologist is \$3,500.

CALIFORNIA.

There is no state geological survey in California, but there is a state mining bureau

which publishes annual reports. It is in charge of Mr. Wm. Irelan, jr. This bureau is supported by a special tax on the certificates of stock corporations. According to the report of the state mineralogist the expenditures for the fiscal year ending 15th May, 1885, were about \$7,800; and the appropriation and mining bureau fund for the period from April, 1885 to 1st October, 1886, was \$25,664.44, of which \$16,457.31 was expended.

COLORADO.

There has never been a geological survey of Colorado in any proper sense of the term. There has been for some years a state geologist who is not salaried and has no appropriation, but who is simply a mining engineer whose clientele is increased by his nominally official position.

CONNECTICUT.

There has been no geological survey in Connecticut for many years.

DELAWARE.

A geological survey of Delaware was made many years ago; and certain geologic investigations are now in progress, but without special appropriation, by the Professor of Geology in the State Agricultural College.

GEORGIA.

There is no regular organised geological survey in the state. Certain geologic investigations are, however, carried on by the Board of Agriculture.

ILLINOIS.

A geological survey of Illinois was completed some years ago at a total cost (including publication) of about \$190,000. Since the completion of the survey a small annual appropriation has been made for the maintenance of the State cabinet, and the curator of the cabinet (the ex-State Geologist) has done some original geologic work.

INDIANA.

The State survey is supported by an annual appropriation of five thousand dollars; but somewhat doubtful intelligence has just been received that this appropriation has been discontinued.

IOWA.

Two Geological Surveys of this State have been made under special appropriations, but the last was completed in 1870, since that date no official appropriation has been made.

KENTUCKY.

An official State Geological Survey is in progress under the direction of Prof. John R. Proctor, State Geologist, Frankfort, Ky., but the amount of the annual appropriation we cannot give.

MARYLAND.

There have been two or three Geological Surveys of Maryland, but these have been discontinued for several years.

MICHIGAN.

A geological survey has been maintained in this state for several years. It is supported by special appropriations. The present state geologist is Mr. Charles E. Wright.

MINNESOTA.

A state geological survey is supported by the income from the sale and rental of the salm lands of the state. The annual expenditure ranges from three to four thousand dollars; the aggregate from 1872 to the 1st August, 1884, being \$39,267.10. This does not include publication.

MISSOURI.

A geological survey of Missouri flourished from 1853 to 1873. It was supported by special appropriations for field work, salaries, &c., and printing which aggregated \$176,185.55. The survey was discontinued in 1876, and has not been re-organized.

NEBRASKA.

There has never been a regularly organized state geological survey in Nebraska; but some investigation has been carried forward indirectly under state auspices in connection with the state university—the professor of geology in that institution being authorized by the university authorities to devote a part of his time to original investigation. Thus the state indirectly pays at the present time about \$1,500 or \$2,000 per year for geologic work.

NEW HAMPSHIRE.

A geological survey of New Hampshire was prosecuted during the years 1869-78 inclusive at a total cost (including publication) of about \$60,000. The survey was discontinued in 1878, and has not been renewed.

NEW YORK.

New York was one of the first states of the union to institute a geological survey. The work of the original survey extended over the years 1837 to 1842, and included general natural history as well as geology. The cost of this work was about \$105,000. The results of the work were published at great length and in magnificent style at a total cost of over \$600,000, making an aggregate cost of work and publication on New York of about \$712,000. This includes all publications up to 1880. The survey proper was discontinued about 1842, and such geologic work as was performed was done in connection with the state cabinet of Natural History. About 1880, however, a survey was re-organized, a state geologist appointed and preparations made for the prosecution of geologic work. The amounts appropriated for the survey during the last few years are not known to us. The state geologist is Professor James Hall, of Albany, N.Y.

NEW JERSEY.

A geologic survey has been in progress in New Jersey for many years. In 1864 an appropriation of \$20,000 was voted for the purpose of making a geological survey of the state within four years; in 1869 a supplementary act was passed authorising the continuance of the survey for a further period of four years with an annual appropriation of \$5,000, and the appropriation appears to have been continued until 1876, when a further appropriation of \$8,000 a year for five years more was passed; and this appropriation in term appears to have been continued without definite action until 1885 when the Legislature made a further special appropriation of \$8,000 a year for five years more, by which time it is expected that the survey will be finished.

NORTH CAROLINA.

The last geological survey of this state was discontinued about 1878.

OHIO.

Two geological surveys have been made in this state—the second by far the more extensive. It was prosecuted during the period from 1869 to 1880 at a cost for field work, &c., of \$35,264; for salaries, office expenses, &c., of \$21,250; and for publications, &c., of \$249,272; or an aggregate of \$355,786. Since 1880 some special appropriations have been made for geologic investigation. The present appropriation is \$3,000 per year, and it is specified in the law making it that it shall be expended in investigations of the petroleum and natural gas resources of the state.

OREGON.

There is not now, and never has been, any regularly organized geological survey of Oregon; but some geological work is performed by the Professor of Geology in the State University at Eugene City, Professor Thomas Condon.

PENNSYLVANIA.

In this state, as in Ohio, there have been two important geological surveys. The cost of the first survey is not known to us. The second survey has been, and is yet, sustained by specific appropriations made by the Legislature at its biennial sessions. Up to 1885 these are as follows:—

Act of 1874.....	\$105,000
" 1876.....	65,000
" 1877.....	100,000
" 1879.....	50,000
" 1881.....	125,000
" 1883.....	50,000
" 1885.....	50,000

Total..... \$545,000

This does not include the cost of publication of reports which were issued by legislative order at a cost of about \$500,000 more.

SOUTH CAROLINA.

There has been no geological survey in this state for many years.

TENNESSEE.

A geological survey was completed about fifteen years ago, and has not been re-opened.

TEXAS.

There have been a number of important surveys in this state, but no official geologic work has been done for some years.

VERMONT.

There was a geological survey of this state many years ago.

VIRGINIA.

A geological survey of this state was made nearly half a century ago.

WISCONSIN.

An excellent geological survey of this state was made during the years 1873-79 at a cost for field work, &c., of \$74,000; and for publication, of \$75,000.

The Discoverer of Anthracite.

Anthracite was discovered in Pennsylvania in 1700, by Nicholas Allen. This Allen, according to the stories and traditions that have been handed down about him, must have been a kind of American Rip Van Winkle. He had come down from the Lake Champlain lumber region and opened an inn on the summit of the Broad Mountain. For a time he led a wandering existence, hunting, fishing, and lumbering, while his wife attended to the wants of thirsty travellers. In one of his hunting excursions he camped out at the foot of the Broad Mountain, at a spot where a coal vein cropped out, and, upon lighting a fire, was astonished at the intense heat it threw off. He also saw that some of the black stone had become red-hot. He dug some of it, and carried it home, when his wife, more practical than himself, pronounced it coal. They saw the coal crop out in abundance, and visions of fortunes that might be realized out of it flashed through their minds simultaneously. So, disposing of their effects, they loaded two large covered waggons with the coal, and set out for Philadelphia, with the intention of marketing it there and discovering its true value. They drove along the banks of the Schuylkill, sleeping in the open air at night. At Ports Town three of their horses died, and the coal was dumped into the river. Wearied and disheartened, the pair returned to the old place at the summit of the mountain, and shortly afterwards Allen laid his faithful wife to rest over the coal vein that proved their ruin, and turned his face toward the West, where, after an uneventful career, he enlisted for the campaign under Harrison and fell at Tippecanoe. — *Iron.*

Lots 25, 26, 27 and 29 in the 3rd range. Some excellent surface shows have been uncovered on these lots and only require capital for developing. Price and particulars given at the office of the MINING REVIEW.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands, 1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place shall not exceed forty acres in area. Its length shall not be more than three times its breadth and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should any person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:— "Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Superintendent's Residence at Experimental Farm; near Ottawa, Ont.," will be received until FRIDAY, 24th June next, for the several works required in the erection and completion of the

SUPERINTENDENT'S RESIDENCE AT
EXPERIMENTAL FARM, NEAR
OTTAWA, ONT.,

Plans and specifications can be seen at the Department of Public Works, Ottawa, on and after Friday, the 10th June next.

Intending contractors should personally visit the site and make themselves fully cognizant of the work to be done, according to the said plans and specifications, before putting in their tenders.

Persons tendering are further notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted bank cheque made payable to the order of the Honourable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party decline to enter into a contract when called upon to do so, or if he fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department will not be bound to accept the lowest or any tender.

By order,
A. GOBEIL,
Secretary.

Department of Public Works,
Ottawa, June 2nd, 1887.

MAIL CONTRACT.

SEALED TENDERS addressed to the Postmaster General will be received at Ottawa until noon on FRIDAY, 5th August, 1887, for the conveyance of Her Majesty's Mails, on a proposed Contract for four years, six times per week each way, between

METCALFE
AND
OTTAWA,

from the 1st September next.

Printed notices containing further information as to conditions of proposed contract may be seen and blank forms of Tender may be obtained at the Post Offices of Greely, Leitrim, Billings' Bridge, South Gloucester, Ottawa, and at this office,

T. P. FRENCH,
Post Office Inspector.

Post Office Inspector's Office,

Department of Inland Revenue.

An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

OFFICE:
UNION CHAMBERS, 14 Metcalfe St.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 17th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Advertising Space.

The circulation of the CANADIAN MINING REVIEW, which has steadily been going up since its first publication, more than five years ago, has now more than doubled the estimate upon which we had reckoned, and its value as an advertising medium to business men who wish to reach the best classes of mine owners and operators, and the mining centres and camps of every province in the Dominion, is consequently very greatly enhanced. The REVIEW is in the widest sense a Canadian journal belonging to all provinces alike; it is the only journal published in Canada wholly devoted to the interests of her mining industries and mineral resources. We would simply draw the attention of those who have hitherto overlooked it, to this matter, promising our best attention and most reasonable terms on any application for advertising space.

Iron and Phosphates.

At the recent meeting of the Royal Society of Canada we had the pleasure of listening to the address delivered to the mathematical, physical and chemical section by its President (Mr. Thomas Macfarlane). Some of the points touched upon seem to us to be of considerable practical interest.

After referring to the death of Dr. Baynes, a member of the section, and announcing as his subject the utilisation of waste in Chemical Technology, Mr. Macfarlane gave a description of the progress which had been made in this respect at the lead furnaces of Freiberg, in Saxony, and at the iron furnaces of Gartsherrie, in Scotland. At the latter place it seems that the furnace gases are made use of on a stupendous scale for the production of sulphate of ammonia, and for other purposes. In another department of the metallurgy of iron waste,

utilisations of a most important character have been accomplished, and to these Mr. Macfarlane referred in the following terms:

"Fifty-six years have elapsed since Karsten plainly pointed out the influence which certain small percentages of phosphorus exercise upon the quality of malleable iron. The presence of 0.3 up to 0.8 per cent. has the effect of making it "cold short," that is of lessening its strength at ordinary temperatures. This element is often present in iron ores in the shape of small quantities of apatite and other minerals, and when this is the case, as in 1840, the smelter has no means at his command for preventing the reduction of the phosphorus and its passage into his pig iron. In the original Bessemer process it was found utterly impossible to remove the phosphorus. All of that element present in the pig-iron stuck to the metal, while boiling white hot in the converter, passed into the steel ingots without the slightest diminution, and into the rails, axles and tyres, into which they were manufactured. It was found that for our modern purposes a much greater freedom from the weakening element was demanded than in Karsten's time. For rails 0.1 to 0.2 per cent. phosphorus was permitted, but for steel of a higher quality the pressure of one tenth of these quantities became the limit. As the demand for steel to replace iron increased, so also did the efforts of iron masters to apply cheap and inferior (because phosphoric) pig-irons in the production of Bessemer steel. The ores free from phosphorus were scarce, and, if we except the Cumberland hematites, had to be brought to England from Spain, Algiers and Sweden.

"At last in May, 1879, the problem was solved by Bolckow Vaughan & Co., at Middlesborough, who were the first to carry out the invention of Thomas & Gilchrist, since become famous as the "Basic process." By making use of a basic lining of bricks in the converter, containing not more than 10 per cent. silica, manufactured from dolomite with silicate of soda as a binder, and employing a basic slag containing not more than 20 per cent. silica, and continuing the "blow" 2 or 3 minutes after the removal of the silicium and carbon, those inventors were able to reduce the phosphorus in common pig iron 1.5 to 0.4 per cent. and drive it as phosphoric acid into the basic cinder. The consequences were far reaching. Inferior ores and pig irons became available for making Bessemer steel, and great reductions have taken place in the price of rails, of which our new railways have had the advantage.

"But these were not the only consequences of this invention. Chemical manufacturers began to face the question as to how the phosphoric acid thus separated could be made use of. Large quantities of Thomas & Gilchrist slag were accumulating at the steel works in England and elsewhere, and it was found to contain from 16 to 20 per cent. of phosphoric acid. Compared with our Canadian apatite it seems to be a meagre raw material for fertilizers.

Nevertheless it was used for making these, and an article called Thomas' Precipitate was put upon the market by German manufacturers. But before this business had time to develop, it was found that by applying the slag itself as a manure, without any preparation beyond grinding to a very fine powder, the most satisfactory results could be obtained. The problem of utilising it has, therefore, been attacked and solved, and the phosphorus which, for fifty years, was the dread of the iron-master, has now no terrors for him, and has reached at last a sphere of widely extended usefulness in agriculture.

"It would be rather an undesirable result if this saving of waste should have the effect of reducing the value of our apatite deposits. Yet the most recent investigations point in this direction. In the *Chemiker Zeitung*, of March last, the following ultimate analysis of the Thomas slag is given:—

Phosphoric acid.....	19.02
Silica.....	8.20
Manganous oxide.....	5.24
Ferrous oxide.....	8.06
Ferric oxide.....	5.14
Lime.....	49.60
Sulphur.....	0.60
Magnesia.....	3.40
Alumina.....	1.10

100.66

"Small crystals having been discovered in the slag possessing the composition of Quadrobasic phosphate of lime, the proximate composition of the slag has been computed from the above analysis with the following result:—

Quadrobasic Phosphate of	
Lime.....	49.02
Silicate of Lime.....	15.85
Lime (uncombined).....	11.00
Sulphide of Calcium.....	1.35
Manganous oxide.....	5.24
Ferrous oxide.....	8.06
Ferric oxide.....	5.14
Magnesia.....	3.40
Alumina.....	1.10

100.16

This view of its composition is supported by the fact that the slag is decomposed with facility by dilute acids, and further 8.7-8 per cent. of its phosphoric acid is soluble in a solution of Citrate of Ammonia, a circumstance that would indicate its agricultural value to be equal to that of the precipitated or reverted phosphoric acid of artificial fertilizers. This is just what field experiments with it, in an extremely fine condition, have proved. Its agricultural value has been found to be equal to the phosphoric acid contained in Thomas Precipitate or bone ash.

"With reference to price it is calculated that one pound of phosphoric acid, contained in the finely ground basic slag, can be delivered for about one penny. If we take the value of 80 per cent. apatite in Liverpool at 10c per unit., or about $\frac{1}{2}$ per lb. of tribasic phosphate, then the price of the phosphoric acid in it amounts to very nearly 1d. per lb. This is the same price, but a great difference lies in the fact that

while the slag is ready for the uses of the farmer, the apatite is not, and its phosphoric acid has still to bear the cost of manufacture. One pound of phosphoric acid contained in high grade super-phosphate, made from Canadian apatite, cost in 1886 $2\frac{4}{10}$ pence. From this and from the experience gained in Scotland and Germany regarding the relative agricultural value of soluble, precipitated and slag phosphate, it seems plain that making super-phosphate will soon become a thing of the past, and that our apatite miners will require to seek some new method of applying their mineral to agriculture, so that it may be able to compete with its new rival—the Thomas & Gilchrist slag. This is a problem to which our chemists and agriculturists should address themselves with the least possible delay. Very likely, by melting apatite with basic fluxes and grinding the product extremely fine, a material might be produced capable of direct and advantageous application to crops."

There were numerous other important subjects brought up in Mr. Macfarlane's address, but this matter of iron and phosphates seems to us to have a special interest for our readers, and we have, therefore, placed it before them in detail.

Is Mining a Risky Business?

The lottery is declared unlawful because it dissipates the earnings of the people, but compared with it the game of chance now played in the Ontario and Quebec Land offices under existing laws and mode of locating a claim with reference to a discoverer obtaining the reward of his labour, the lottery is an honest and seemingly legitimate business. Its patrons risk only the price of a ticket, and it is win or lose and the amount lost is known but not so with the application for a mineral lot in the Provincial Land Office, where profits to be derived, from labour and prospective value are lost along with the labour and expenses of discovery added. We want a new and more just code framed so that by making the location of a claim or discovery *on the ground in a proper manner first* (and then at the Land Office) imperative, the discoverer will receive the just reward of his labour.

Protection Wanted.

An American exchange commenting upon the wholesale destruction of life at the Nanaimo mines very properly suggests that more protection should be accorded to miners in deep shafts than has heretofore been given them:—

"Many of the coal mines on the coast have been worked as cheaply as possible, owing to sharp competition—so it is alleged—and due security has not been provided for, either in timbering the mines or in furnishing modes of escape in case of fire or caving in of shafts. One shaft is not enough in any mine, any more than a single stairway is sufficient in a mammoth hotel. There should be some law to protect the lives of labourers in mines providing for means of escape, &c. Laws of this kind do prevail in some places. They should be more universal. In default of such legal protection, the labour associations might restrict their members from labouring where proper safeguards are not provided."

Our Mines and Minerals.

W. A. Carlyle, Montreal.

Facing a sea of details and technical terms, understood only by the initiated, it has been difficult to make this subject generally instructive and popular. Still this part of the great natural resources of Canada cannot fail to excite deep interest among those who are studying the wealth and power of our country.

When we begin to write about the mines of Canada we have before us a vast extent of territory, as the name *Canada* is no longer confined to a narrow strip of country along the River St. Lawrence and the great lakes, but from ocean to ocean, from the turbulent Atlantic to the calm Pacific, rings out the name Canada; and then dies away in the vast regions of the North and the Arctic Ocean.

Everywhere throughout the different provinces people are flocking to establish new homes; and great regions, not long since the home of savages, are beginning to blossom with the labor and industry of the white-man's civilization, while the cheerful whistle of the locomotive re-echoes through the valleys and across the prairies of that which no longer can be called the "Great Lone Land."

From the beginning it must be remembered that Canada can scarcely be regarded as a metalliferous country of explored richness, although her mines are numerous and extensive, only awaiting energy, capital, and a more favorable state of the markets for their development. Canada has been gifted with almost every natural wealth, but the vast forests are fast melting away before the choppers axe to satisfy demands from all parts of the world, and the time is not far distant when this seemingly inexhaustible supply of timber will fail, and other regions and new countries must become the sources of this commodity. The fisheries seem an illimitable source of wealth as periodically the deep gives up its revenue, paid in gigantic swarms of fishes, but even here experience teaches that these great harvests may be devastated and ruined. The mineral wealth of this country will yet become of greater value as the demand increases and railroad and other facilities improve, though at present many mines remain idle and undeveloped.

If you will permit me to briefly state a few well-known facts concerning the geology of this continent it may aid to a better understanding of our subject, as mineral deposits are not scattered about hap-hazard, but are always found under certain circumstances and in certain localities.

It is doubtless that in the beginning the globe was in a molten state, and eventually, becoming cooler, a hardened crust was formed, which in turn was violently bent and folded as the cooled surface contracted, thus pushing up great ridges that since have become the nuclei of all mountain ranges. As the temperature decreased the vast impenetrable and enveloping cloud of vapor dissolved into rain, and oceans and seas, rivers

and brooks were formed, which, aided by heat and frost, began their attack on the great rock masses, wearing and grinding them into sand and mud, which, carried out by the waters, were spread over the vast ocean floors. In studying rocks, it is seen that the granites and gneisses, such as form our great Laurentian hills, are the oldest known, forming as it were the floor of the earth, or the lowest part of the rocky crust; and by their disintegration and crumbling away there have been built the great deposits of newer rock, thus sand and mud have been consolidated by intense heat and pressure into sandstone, slates and limestone. These newer rocks can be readily distinguished as they lie in layers or strata as one bed has been successively deposited upon the other, while in most of these strata are the fossil remains of animals that lived myriad years ago, the great primeval oceans having been the birth-place of most of them. Glancing at a map it is seen that along the eastern and western coasts of the continent are two great mountain ranges, the Appalachians and the Rockies, while between extends a great inland sea or plateau. When geologists examined these ranges the startling discovery was made that the great mountain masses, whose peaks often towered 10, 12 or 13,000 feet high, consisted greatly of those stratified rocks all twisted and piled up on end, and on the loftiest summits were found the fossil remains of animals, whose shells buried in the mud and sand of ancient ocean bottoms, were firmly imprisoned when these were hardened into stone.

After careful observation the secret of this enormous uplifting from ocean depths to mountain summit was learned from the fact that the beds of the Atlantic and Pacific oceans had subsided, and being very strong and firm, on sinking down had pushed with profound force against the more yielding continental masses, forcing up into these mountain ranges the great areas of rock. During the past four years Dr. Dawson has brought to light many more marvellous facts concerning the building up of these Pacific coast ranges. It has been found that there are four distinct ranges: (1) the Rockies, (2) Gold range, (3) Coast range, and (4) a submerged range, of which Vancouver and Queen Charlotte Islands are summits, and by the different ages of the constituent rocks it has been proved that these ranges have been formed at different periods, and the most inland, the Rocky range, is the youngest. To push up the towering heights of this great mountain chain, natural forces have been so great, the shoving energy of the Pacific Ocean bed has been so terribly grand that these deeply-rooted mountain ranges, the Vancouver, Coast and Gold ranges, over 400 miles in width, have all been pushed bodily towards the east, folding up inland plateaus into the grand precipitous cliffs and precipices of the Rockies.

All this is pertinent to our subject, as in these disturbed regions are found the great mineral deposits, collected mostly in great

cracks or fissures made by the bending and distortion of the rocks. To these great earth movements are due the differences in the coal measures. Coal beds are the remains of forests that flourished under such favoring climates that some plants, now seen as small club mosses, then grew as trees, while all vegetation grew in rank luxuriance. These great forests were finally submerged by the encroaching seas, and upon them were piled great depths of sand and debris, crushing down these deposits of vegetable matter into the hard black coal. Where this has lain undisturbed by those earth movements, as in the prairie beds of the North-West, the coal or lignite is poor, soft and watery. Where subjected to some upheaval or twisting the quality, known as soft coal, is much better, but where the beds have been all twisted and crushed, as in the mountains of Pennsylvania, the oily and volatile matters have been passed out, leaving the hard, shining hard coal or anthracite. In Canada anthracite coal is found only in Vancouver Island or along the Pacific coast, while that of the prairie province is poor until the mountains are approached.

The principal ores of Canada are gold, silver, copper and iron, and, though very valuable mines are known, yet none are startling in their extent or value when compared with those of Australia, Spain or the United States. Much capital has been spent upon their development and much has been lost, partly through ignorance and blundering, and partly through natural disadvantages and insuperable competition. One expert has said:—"that among the industrial enterprises begun from time to time in our Dominion few have been more unsuccessful than seeking the development of her vast mineral resources. The fault being not always through lack of mineral, but more often through blundering and inexperience on the part of the operators."

The rapid settlement of our country and the wide extension of the railroad system are beginning to make the opening up of good mines, long known, possible, while their value is rapidly increasing as the promises of better profits brighten. One thing to be deplored is that at present much of the energy and capital being expended in Canadian mining is American and not Canadian.

In this age of iron, now but at its dawn, when the use of this invaluable economic metal is spreading throughout all the branches of the arts of men, fast superceding timber and stone in many industries, the iron mines of Canada have attracted much attention. The present annual importation of iron and steel exceeds \$15,000,000, while since confederation \$235,000,000 of foreign metal has come into Canadian markets. The question has often been raised why do our own iron beds not supply this growing demand. The great reason is that the cost of smelting or converting the ore into iron or steel is much greater than in some other countries, as Britain or the United States, from two causes—

I. The foreign iron beds are much vaster in extent;

II. The want and greater cost in Canada of suitable fuel.

In the United States some of the most valuable mines are found in rocks the same as comprise our Laurentian Hills, and all so extensive as to seem practically inexhaustible, some producing from \$500,000 to \$1,000,000 worth of iron annually. With such deposits it is safe to erect the very extensive mills and blast furnaces, which alone can now be profitable. Many of these noted mines are found in and near the great coal fields, in fact, in some rich mines, beds of iron are in direct contact with beds of coal. This is a great factor in iron mining, as it requires 2,000 to 3,000 tons of coal for smelting 1,000 tons of iron ore. Under such favourable circumstances, when coal can be got for the cost of the mining, good iron can be profitably sold at one cent a pound. Remembering these facts, and the intense competition among the great American Iron Corporations, the position of Canadian iron mining may be better understood.

In Ontario and Quebec iron has been mined in many different places with varying success, the ore being smelted at the mines or shipped to American furnaces. But the dearth of cheap coal and poor means of access have made this enterprise barely profitable. North of Lake Ontario are several mines as the "Coe" mine near Wollaston, from which 45,000 tons of ore were shipped to Cleveland from a vein of very pure ore 20 to 40 feet wide. At Bedford, in Frontenac, is a rich bed 100 feet thick, while several are near Madoc, one yielding 40,000 tons of ore.

In Quebec, furnaces have been worked at St. Maurice, near Three Rivers, since 1737, while good beds are known at Bristol, Sherbrooke and Leeds, and at Moisu are great beds of iron sand that, however, proved unprofitable. In the Laurentian rocks at Templeton and Hull are rich deposits, and it is not at all improbable that very rich finds will yet be made in these rocks when this country becomes more cleared. Iron is found, of economic value, around the shores of Lake Huron and Lake Superior, and in British Columbia rich mines are known near excellent coal fields. On Lexada Island are deposits 25 feet thick, while the coal beds of Comox Harbor are only 20 miles distant, but the industry in this part of Canada awaits the increasing demands of a much larger population. But it is in Nova Scotia, along its northern part, that the best Canadian iron beds are found in large veins intersecting rocks of all ages. The coal fields are close at hand, with every facility for shipment, but after many spasmodic attempts these mines are now almost idle, unable to overcome the great foreign competition.

Furnaces have been built, but the history of iron-smelting in this Dominion is neither a long one nor a brilliant one; the list of failures is greater than the list of successes, but such is

likely to be the case where enterprises are too often undertaken by persons of little or no experience.

To be continued.

The New Tariff.

(Iron Trade Review.)

The best possible tribute to the wisdom and efficiency of the present American tariff is the fact that Canada has adopted a system modeled very closely upon it and differing chiefly in the fact that it levies about two-thirds of our duties upon articles entering that country. The revised and amended schedule on iron and steel products appears on another page, but it may be interesting to bring into comparison herewith some of the principal articles in the schedule, under the old and the new duties:

Old Duties.		New Duties.	
Pig iron.....	\$2 per ton	\$4 per ton	
Slabs, blooms, puddle bars...	Not specified	9 "	
Bar iron.....	17½ per ct.	17 "	
Flats, 1 in. wide and less.....	17½ "	13 "	
Round iron, 7-16 to ¾ in. diam.	17½ "	15 "	
Round iron, less than 7-16 in. diam.....	17½ "	25 per ct	
Iron and steel boiler plate.....	12½ "	30 "	
Malleable iron and steel castings.	25 "	\$25 per ton	
Cast iron plates and vessels.....	25 "	16 "	
Cast iron pipes.....	30 "	12 "	
Sheet iron, below 20 gauge.....	12½ "	12½ per ct	
Hoop or band iron.....	Not specified	\$12 per ton	
Rolled channel and T iron.....	12½ per ct.	12½ per ct	
Iron bridges and structural iron.	25 "	1½c per lb	
Iron and steel forgings.....	25 "	1½c "	
Wrought iron and steel scrap....	Free	\$2 per ton	
Steel ingots, blooms, &c., 4c or less per lb.....	12½ per ct.	30 per ct.*	
Steel ingots, blooms, &c., above 4c per lb.....	10 "	12½ "	
Wire rope.....	25 "	25 "	
Hardware.....	30 & 35 "	35 "	
Firearms and surgical instruments.	20 "	20 "	
Cut nails and spikes.....	10 per ct and ½c per lb.	1c per lb	
Street railway rails.....	75 per ct.	\$6 per ton	
Safes.....	25 "	35 per ct	

*But not less than \$12 per ton.

The re-adjustment of rates has proceeded upon the theory that Canada has iron ore and coal in close proximity to each other and special facilities for the production of charcoal iron, and that the exclusion of foreign products would be more than compensated by the resulting growth of the Canadian iron and steel industry. The annual Canadian consumption of pig iron is 250,000 tons, not inclusive of steel rails. To make this quantity in Canada, 750,000 tons of iron ore, 120,000 tons of limestone and 750,000 tons would be required, and considering the benefit which would accrue to the country by the development of the iron industry the Government felt that it was justified in losing the coal duty of half a million.

The United States has little to lose by the new arrangement, and it would certainly be in bad grace to characterize the present policy otherwise than as pre-eminently politic on the part of our neighbour. May she reap great national and material results from the new system.

Coal Dust in Mines.

Some time ago there appeared in these columns the report of a valuable paper on this subject read by Mr. M. Mercier before the Manchester Geological Society. The following discussion on the paper took place at a recent meeting of the organization and is full of interest to our readers:—

Mr. J. S. Burrows said Mr. Mercier had dealt with several means for lessening the quantity of dust in a mine. He (Mr. Burrows) had since

been looking into the question, and it seemed to him that in places where the haulage was done by machinery they had to face conditions which must of necessity cause a large quantity of dust to rise from the tubs. He had found that when the roads were packed the dust had gone a long way into the pack and lodged there. He had swept one piece of road, but in less than a week it was fully coated with dust. He had tried water on a small scale, and he found that unless he put on a heavy quantity it simply ran away in little globules. If they put on a large quantity of water they wet the timbers, they made the roads slippery, and would no doubt eventually cause the floor to lift. In his opinion the real danger which arose from the presence of dust in a mine would be best overcome by providing some substitute for the use of gunpowder, rather than take so much trouble as would be necessary to get rid of the dust.

Mr. Mawson said the idea of having water pipes laid down along the roadways seemed to be a good one, but it would entail very great expense and he thought would be found hardly practicable in mine. The best suggestion was to have a water tank carried like a tub along the roads, which would discharge the water through a rose.

Mr. Burrows thought such an arrangement would require an enormous amount of water if they were to effectually lay the dust.

Mr. Mawson suggested that if the dust were once properly swept up, and the water tanks used, the road might be prevented from getting dusty again.

Mr. Burrows, as an illustration of the quantity of dust that was constantly accumulated mentioned that in one double road 900 yards long, they filled at least 18 tubs every night with dust, and in addition to this they had extra cleanings up.

Mr. Hall, Inspector of Mines, thought that they might be able to prevent the dust blowing off the tubs by sprinkling the tubs with water as well as the roads. The dust question was a very important one and would have to be tackled in some shape or another. He had been reading a description of a water-sprinkling machine brought out in the North of England which could water 800 yards of road with less than a thousand gallons of water; this was a tank that went on wheels with a longitudinal tail from which the water was discharged. He thought colliery managers sometimes overdid the difficulty of watering mines, so far as lifting the roads was concerned. There was no doubt a good deal of difficulty in some kinds of roads, but if they persevered with the water and got the temperature something like regular, this difficulty would cease.

Mr. Burrows did not think that sprinkling the tops of the tubs with water would prevent the dust rising.

Mr. Mercier said in watering the roadways the idea was not so much to soak the dust as to have a fine spray thrown into the current of air. It would be almost impossible to saturate the dust, but if the moisture were carried along on the air it would effect the purpose. He did not think, even with a soft warrant floor, that if the water were simply mixed with the atmosphere it would affect the floor to any extent. With regard to the dust blowing off the top of the tubs this was a difficulty which might be very considerably overcome by improving the roads and using closed tubs. At one colliery in South Wales where they had been blocked with dust when using open tubs, by adopting the means above stated they had been able to reduce the dust about two-thirds. He thought the pit tubs had more to do with the dust ques-

tion than anything else, and where iron boxes had been introduced the mines were nothing near so dusty as where wooden boxes were used. In using a water cart a considerable difficulty was in getting into the return roads, and the laying down of the requisite lines of rails would, in some cases, cost quite as much as putting down water pipes by which the mine could be watered automatically. He might add that at one colliery they used compressed air with the water so as to get a very fine spray.

Mr. Burrows admitted that there was a good deal in what Mr. Mercier had said with regard to bad tubs, but whatever they did they could not prevent the dust shaking out.

The Chairman said the whole question was one of great interest to colliery proprietors. The other day he had a conversation with Mr. Wm. Galloway who was a well known authority on the dust question, and he said the practice of watering the roads was largely on the increase in South Wales, but he also strongly recommended that the tubs should be made as dust proof as possible. He further expressed the same opinion as Mr. Hall, that the coal dust question was one which would have to be gone into thoroughly, and if this was done, he was satisfied good results would follow.

Mr. Burrows suggested that but for the danger of explosion attendant on shot firing the coal dust question would not be regarded as being of such great importance.

Mr. Hall remarked that shot firing was not the only cause of explosions, and that whilst there were other contributory causes, the presence of coal dust in the mine must always be a danger and render it desirable that the dust should be got rid of.

The Chairman observed that some persons held the opinion that an explosion might be caused by coal dust alone without the presence of gas. He did not hold that theory, and in his opinion it was impossible to have a serious explosion without the presence of gas. In some of the extensive collieries in South Wales, they might find in almost every case a "cap" in the main return, and the colliery officials would tell them that this was dust, and it was one of the reasons they went for the coal dust theory.

Mr. Mercier remarked that if the mines inspectors in South Wales were of the same opinion as the colliery officials on the coal dust theory, it was time there was a change.

Geology of the Gold Regions.

How the Ancient Streams of the West Developed its Auriferous Placer Deposits.

From a paper read before the Royal Society at the Annual Meeting at Ottawa, May 27th, 1887, by Amos Bowman, Mining Engineer, of the Geological Survey of Canada.

We extract from Mr. Bowman's paper, read before the Royal Society, the following description of one of Nature's most interesting operations, which will be best understood and appreciated by those who have been actually engaged in gold mining in the Western or Rocky Mountain regions of the Dominion.

Mr. Bowman's paper covered the general subject of the Gold Bearing Rocks of British Columbia, about to be reported upon by the Geological Survey, and gave introductorily a general view of the field described and its geological problems. This was followed by an account of the different formations found to be gold bearing, that is to say, the distribution in time of the gold bearing rocks; then of the geological distribution of the productive regions

overrun since 1858, and the formations to which they belong. The succeeding portion on "mechanical enrichment, its methods and degrees to a stage adapted to placer mining and the natural forces at work," is what we have here copied.

The paper continued to consider the processes of chemical enrichment, the results of which are witnessed in the quartz veins of the country, having for its ground material the deep water sediments, commonly described as slates, which were off shore palaeozoic sediments adjacent to very ancient crystalline areas; and concluded by a description of some of the most noteworthy features of the cordilleran system in Canadian territory; being accompanied by a map and six sections.

The Natural Forces at Work.

CONDITIONS OF PLACER MINING.—Great wealth in gold may still exist, however, where placer mining has not been successful. This will become apparent when I point out the operation of the natural causes of workable placers; and will form a significant comment upon possible gold countries which are not placer mining countries, such as the Appalachian gold regions.

Three circumstances have to combine to make a good placer-mining region: first, the veins must carry free gold along with the baser metals; secondly, the conditions of natural concentration in streams must have operated upon them; and thirdly, after such operation, the product must be accessible to the miner. Either of these conditions wanting, though we walked over untold millions, we could not realize it by successful placer-mining. In California all three of these purely geological considerations happened to be superb. In British Columbia they are not exactly identical, as I have elsewhere pointed out.*

SILTING UP OF STREAMS.—A peculiar circumstance pertaining to profitable placer mining regions is to be observed in connection with this silting up or filling of previously eroded canons, I refer to its universality in all the famous gold mining regions. Hence it has occurred to me that I should perhaps have included it among the above mentioned necessary natural conditions of placer forming. The process appears to have served as a means of arresting the gold. In its absence the gold would have been hammered between the boulders along with which it travelled, and the bed rock of the stream, until it became flattened and frequently sub-divided. By continued erosion and undermining this process of hammering and subdivision would of course be continued indefinitely, until it is readily conceivable that all the gold entering a river would, unless otherwise retarded, be carried down stream, and finally scattered again among the sediments of the plain.

CAUSES OF SILTING UP STREAMS.—The silting up of the old river channels was due to a cause which can be very precisely stated, viz:—An alteration in the transporting power of running water, from greater to less. It arose from a different combination of its two factors of *Volume* and *Grade*. Prof. Whitney has attributed all of it to a change simply of volume. Prof. Le Conte has attributed all to a change only of grade. Both have drawn important conclusions regarding climate and uplift. As it is plainly a resultant of these two factors it appears to me that the geological problem involved is a more complicated one than has been assumed.

*Address before American Institute of Mining Engineers at Scranton meeting, February, 1887.

Method and Degree of Mechanical Enrichment to a Stage adapted to Placer Mining.

The tertiary streams of the north-western Pacific coast were silted up, as has been stated, and covered in some places by lava flows, in others directly by post pliocene glacial clays and drift. Examples are seen of the former in the chasms of the "Green Timber," on the Cariboo road, and in the bluffs of the Pentateucent river, opposite Quesnel; and of the latter in every mining camp in Cariboo.

As the silted gravels were derived from the adjacent older formations, which have been described, it is proper to remark in this connection that the distribution of the auriferous deposits is nevertheless not necessarily co-extensive with the gold bearing rocks. It was limited by the conditions necessary to bring about the phenomenon of silting or filling up with detritus, taking the place of preceding conditions of erosion and transportation. Usually this occurred *only for a short distance* along the course of the older eroded valleys. The effect is very striking in placer mining regions. Down stream they are represented by sands and clays, containing very much less gold, as well as gravel, than in the deepest part of the cycloid of erosion.

POST-TERTIARY AND RECENT ENRICHMENT.—In the post-tertiary, or rather recent period, concentration of gold into workable placers took place, generally speaking, only in the silted up river valleys. Its method was that of replacement, and sorting of the material of the bench or terrace epoch. This could not have taken place to any great extent during the post-tertiary Terrace epoch; because the raw material so to speak, was only then being deposited, and it was upon this that concentration did its work. *Itself* had buried all the pliocene concentrations out of sight, and out of reach of the flowing waters of that valley-filling period. Examples were found in all the early diggings of 1858-9 along Fraser river.

INTERVENING OF THE PLATEAU LAKE PERIOD.—The transformation of valleys into lakes, and the confluence of lakes into one or more inland seas of vast proportions—from causes not yet satisfactorily explained—put a stop to the effective concentration of gold until the turning point was reached at the close of the pleistocene (post-tertiary), when the filling had been completed, and eroding conditions were once more established. Any one who has seen the map of British Columbia, and still more, any one who has seen the country itself will recognize the far reaching and general importance of this plateau lake period by its remaining and enduring landmarks.

THE "BED ROCK" MISSED AND FOUND.—Nearly all the benches and washes of the Fraser and its tributaries, profitably mined by the placer miners after 1858, and by the Chinese and Indians in subsequent years, accordingly belong to Recent time. No bed rock was reached by the early miners of British Columbia until they got into the higher mountainous region of Cariboo, where the recent erosions had tapped some of the higher bed rock channels left intact on the sides of the older valleys during their erosion. They are known among the placer miners as bed rock benches, or "high channels," and are generally understood by the miners themselves to be older in date than the deeper deposits of the tertiary streams. Examples are universal in any mining country.

OLDER AND NEWER TERTIARY STREAM CHANNELS.—Similar bits of streams running on bed rock were often not older, however, than the recent erosions, as is frequently seen where

the recent eroding stream had been displaced by a slide. It is true, however, that the highest old side channels were, generally speaking, the oldest. They are all hidden in Cariboo District by a universal covering of drift.

The deepest channels cut during the tertiary period are in Cariboo generally from 40 to 120 feet underneath the present stream beds, and separated from the stream concentrations, of recent date (like those of the Fraser), by beds of clay marking the separation between pliocene tertiary, and pleistocene or older post-tertiary. Nothing is more important to the process of drift mining, or better known to the miner than the "clay." It sometimes "gives out," to his grief, from removal by a side stream or other causes; in that case involving much pumping or expensive working.

WHY THE TERTIARY STREAM BEDS ARE RICHER.—Now these older channels of the tertiary period which ceased cutting and began filling, as already remarked about the close of that period, necessarily contained in their deepest gutters the accumulated gold of the entire tertiary eroding period. The history of the concentrating process accounts for the richer placer deposits in most cases.

The bulk of the gold has been taken out in Cariboo District accordingly by drifting.

Not only less time, but much less disintegrated country rock was represented in the recent erosions which terminate in their downward wear above the clay.

It would seem incredible were it not a fact that in less than two years after the commencement of gold mining in British Columbia, near Hope, the perseverance and ingenuity of the California prospector had actually explored and exploited the valley of the Fraser river for a distance of four hundred miles from the starting point, at Hope, into the interior of British Columbia, and as early as the fall of 1860 had penetrated the hidden mystery of the tertiary streams, and found therein what he was seeking. The wealth of Keithley, Harvey, Cunningham, & Antler creeks was quickly disclosed. Soon after them followed the famous discoveries on Williams & Lightning creeks. They were successively revealed by accidental bits of "shallow bed rock," along with a good deal of shrewdness, on the part of the prospector, directed to a solution of the problem.

Latest English Quotations.

London advices report that the market during the past month has been without any special feature, the only exceptions being the large sales of South Carolina Phosphates, and the demand which has arisen for Sulphate of Ammonia.

MINERAL PHOSPHATES.—There is no material change in Canadian, but as the St. Lawrence is again open to navigation, dealers anticipate a renewed interest in this high grade Rock. A very large business has been done in South Carolina Phosphates, as owing to a number of steamers arriving at American Ports without profitable employment, they became available at unprecedentedly low freights for bringing home Phosphate, and most of the large manufacturers were able to secure supplies at about 6½ l. to 7 d. per unit, delivered at U.K. Ports. Belgian

Phosphate has been in active request since our last, and several contracts have passed both for immediate and next season's delivery, but at ruinous prices for the raisers. Messrs. Couper, McCarnie & Co. are offering all qualities from 20 to 25 per cent. to 60 to 65 per cent. Sonme Phosphate still remains actively in demand, and raisers are unable to keep pace with it, though with the fine weather many of their difficulties will be removed.

The following shipments of Canadian ore have been made from Montreal for month ending 31st May last:—

Date.	Shippers.	Ship.	Destination.	Tons.
May 18.	Wilson & Green.	s.s. Ovenholme	Liverpool.	613
" 23.	Gillespie, Patterson & Co.	s.s. Bannewall.	Hamburg	104
" 25.	Anglo Canadian Phosphate Co.	s.s. Colina.	Glasgow.	200
" 27.	Wilson & Green.	s.s. Carropus.	Liverpool.	63
			Total....	980

Latest quotations in England for Canadian Phosphate is 11½ d. to 11¾ d. per unit with one-fifth rise on a guarantee of 80 per cent.

Ocean freights are ruling low this season. Sailing vessels from 2s. to 3s. 6d., and for steamers from 3s. 6d. to 6s.

Captain Williams has been appointed Superintendent of the North Star Mines, vice Mr. W. H. Smith resigned. Present output is expected to assay 88 per cent.

A well authenticated rumour is current that a large and valuable bed of phosphate has been discovered on the lands of Troy Lake Mining Company. An investigation with a view to determine the extent and value of the discovery is being made.

At Little Rapid's Mines the usual output of high grade ore continues. The tramway from the mines to the river has been completed and thoroughly equipped. The ore will now be hauled from the mines to the river edge at a minimum cost. Shaft B has reached a depth of over 200 feet, and shews a vein of pure apatite full width of shaft. Mr. Pickford, sr., of London, England, accompanied by Mr. Green, of Montreal, and other phosphate experts, lately paid a visit to this valuable property and were greatly pleased with the general appearance of the property and its management.

The Otty Lake Mines are now in good working shape; a third pit has been commenced upon this month and yields a large quantity of high grade ore. The present output is 15 to 20 tons daily with about 50 men employed.

Messrs. Butler, Breed & Co., Boston, propose distributing the following circular very widely among the farmers of New England. It is of much interest as shewing a movement in a direction of vast importance to our Canadian Phosphate Industry:—

GROUND PHOSPHATE.

"It is very generally admitted that if it were not for the high prices charged for commercial fertilizers, and the doubt often existing in the minds of purchasers as to their quality, and the trustworthiness of the analysis, the use of artificial means for supplying worn out land with the much needed elements for plant food, would be very much more general, and the quantity that would be used by farmers largely increased.

"The undersigned have arranged to put on the market *Fine Ground Phosphate*—soluble in the water of

the soil—superior in quality to Ground Carolina Phosphate, because containing a greater percentage of phosphoric acid. In support of the growing practice of using raw phosphate, we quote the following from the Annual Report of the Conn. Agricultural Experiment Station for 1884—page 30:

"The raw phosphates, South Carolina and Navassa, and the phosphate guanos, have been used by some of our farmers instead of super-phosphates with satisfactory results. While on one hand, the acid phosphates are more quickly available, on the other hand, much more phosphoric acid can be applied to land for the same money, in the form of raw phosphate, which latter advantage may make the raw material in some cases the more economical, as in seeding down to grass, or preparing land for fruit trees, &c."

We also quote from a letter from A. H. Ward, Esq., Agricultural Editor of the Boston Post, as follows:—

"To render raw phosphates as quickly available as the acid phosphates, all that is required is to compost it with fermenting manure, which can be done as the manure is made during the winter. Soluble phosphoric acid, whether made from bones or the mineral phosphates, is all of equal value as plant food."

"The degree of pulverization controls, almost without exception under similar conditions, the rate of solubility, and the more or less rapid diffusion throughout the soil."

"Soluble phosphoric acid, when applied to the soil, reverts to its original condition in a short time. But it is better to use the Fine Ground Phosphate and render it soluble by the aid of fermenting manure, in preference to using acids, which more than double the cost without increasing its ultimate value as a fertilizer."

"When the raw phosphate is to be used without mixing with manure, it should be put on the land about six months earlier than super-phosphates, and after the lapse of that time, a large percentage will have become soluble, and the balance will be assimilated as fast as the water of the soil can act on it."

Mr. Milne, representing Messrs. W. & H. M. Goulding (Limited), of Dublin, the largest manufacturers of phosphates in Ireland, was recently in Montreal in connection with the purchase of high grade ore. He reports that the prospects on the other side are very favourable.

Writing anent recent cablegrams to the effect that all the phosphate deposits of South Carolina had been "cornered" by a syndicate of wealthy capitalists the *Canadian Trade Review* says:—

"The object of the men who control the Carolina phosphate fields is to put up the price of crude rock. They are reported to have secured absolute control of every ton of rock mined in the state, and propose to regulate prices at will. Last year the aggregate reduction of South Carolina phosphate rock was 449,603 tons, of which 381,603 tons were exported and 68,000 tons were consumed by the local fertilizer manufacturing companies. The aggregate value of this production was, in round numbers, \$2,000,000. The total quantity of phosphates shipped from Canada last year was 25,974 tons valued at \$431,951, but the Canadian phosphate lands are probably capable of yielding more mineral than those of the state referred to."

MINING NOTES.

Nova Scotia.

The Brookfield Mine is showing up well.

Recent tests made from quartz taken from the Parker and Douglas, Bartling gold mine, at Malaga, have given very satisfactory results. Two leads are being prospected, one being about 42 inches wide between the walls, and the other 10 inches. The yield from the widest lead at a depth of 50 feet was one ounce to the ton, and from the other two ounces and one half to the ton. The owners of this mine intend at once to put up a 20-stamp mill, which will be the largest in the county.

The *Critic* announces that a four foot gold bearing lead has been discovered on the Stemshoon property, Mooseland.

The Provincial Government has introduced a bill to prevent strikes and lockouts in mines. The principal section reads:—

"Whenever any dispute shall arise between the employer and employed of such mines in regard to wages, mode of working, or any other matter, the employer shall not dismiss or lock-out the employed, nor shall the employed strike or abandon work, without first laying complaint in writing before the commissioner."

The bill provides that when the employed, or a majority of the employed, shall make a complaint in writing to the Commissioner of Works and Mines, he shall, in his discretion, submit the whole matter to a Board of Arbitrators. This award is to have the same force and effect as a judgment of the Supreme Court and shall operate as an attachment on the whole mining property, after payment of royalties, if the award should be against the employers; and shall bind a certain amount, equal to 14 days wages, which the Act provides shall be reserved and kept from the employees, to meet any such contingencies, in the event of judgment going against the employees.

"The object of the Act" says the *Gazette* "is a good one, but such a law we fear would prove inoperative."

"We doubt if either man or master would willingly accept it. The arbitration clause alone might be productive of good, as tending to bring the opposing forces together before a tribunal which both could respect, and in the integrity of which each could place confidence. But neither would care, we think, to become liable to such a penalty as is provided for a refusal to acquiesce in the court's decision, for there are instances when each party to a labour contest is thoroughly convinced that he is right and that to retire from his position would be to accept ruin. In such a case a confiscation of the property of the conscientious recalcitrant would be an act of tyranny, that we doubt if any British court would sustain. And it is in the settlement of such cases that the great difficulty in the labour problem lies."

The official returns received for month of May are

Fifty men are at work at the Essex Gold Mines, at Tangier. The foundations of the new Wiswell Mills are nearing completion.

The *Critic*, of 17th inst., states that Mr. Tonquoy, of Moose River, brought to town last week a gold bar weighing 106 oz., the work of 10 men for a month. Of this, 14 oz. was mortared by hand from 50 lbs. of quartz, the balance being milled from 34 tons crushed.

Quebec.

Some good specimens of gold and silver ore have lately been brought in from the Portage du Fort district.

Operations at the Asbestos mines have been prosecuted vigorously, and show an average steady output. Prices remain firm.

All the other mines are in active operation, but we know of no special feature to report concerning these. New uses for Asbestos are being gradually found, and an increased and growing demand is found for the lower grades of crude stock, which supply a want for materials where cheapness is required.

The Anglo Canadian Company are continuing operations upon the lines indicated in our last, and both the quantity and quality of output show a steady improvement.

The vein of gold recently discovered in the neighbourhood Mattawa turns out to be even more valuable than at first reported, it having been found to extend for a great distance and to become much richer. The vein crosses beneath the Ottawa river and enters the mountains on the north side in Quebec province. An assay which has been made shows the quartz to be exceedingly rich in the precious metal. Dr. A. M. Earle's discovery was made in the mountain opposite Mattawa and assays made from his specimens give 2 oz., 12 dwt. 12 grs. per ton. Numerous parties are out prospecting and moneyed men in the district are reported to have made investments.

Some further information may be gleaned from the remarks of our correspondent who says "gold was first discovered in this vicinity about the middle of last month." The locality is in the Province of Quebec directly opposite Mattawa and in unsurveyed territory. A number of assays have been made by Mr. J. T. Donald, of Montreal, which give results varying from \$19.00 to \$35.00 per ton, gold. The precious metal is not visible in the quartz, but on being pulverized and subjected to chemical process it has readily been obtained.

Three companies have been organized and among others interested are Dr. Earle and Mr. Adam Burwash, Mattawa, and Messrs. McAllister and Metcalfe, of Pembroke.

Operations are being conducted with much activity at the mica mines of the Villeneuve M. & M. Compy., near Buckingham. A fine quantity of very superior clear white mica is being produced. Very large crystals, shewing a perfectly smooth surface without a speck or flaw, have been taken out within the past few days, and the management report that the twist of the vein has now been passed. Two steam drills are at work, and the company are kept very busy handling orders for home and foreign trade. The management state that the demand this summer promises to be much in excess of former years.

Ontario.

From a circular issued by the Kingston & Pembroke Mining Company we learn that they have 13 distinct mining properties, located along the Kingston & Pembroke Railroad, which are being worked more or less, and are known: 1st.—The Zanesville Glandower, owned in fee simple. Comprises 650 acres, from which 10,000 tons of ore have been sold. Has \$20,000 worth of machinery. There are three (3) openings on this vein, covering a distance of half a mile. A large amount of ore, estimated by a conservative engineer to be 40,000 tons, is in sight in the main shaft. 2nd.—The Grady-Machar Mine. Owned in fee simple, and comprises 100 acres, upon which there is \$2,000 worth of machinery. 3rd.—The Levant Mine. Comprising 450 acres, which is leased for 99 years at a royalty of 15 cents per ton. There are three (3) shafts on this property, from which some 60,000 of ore have already been taken. This property contains the Wilbur mine, which produces ore lower in phosphorus than any Bessemer ore imported into the United States. There is \$40,000 worth of machinery on this property. 4th.—The Lalonde Mine. 100 acres in fee, upon which there is \$2,000 worth of new and improved machinery. 5th.—

The Culhane Mine, 100 acres in fee and \$2,000 in machinery. 6th.—The Williams Mine, 100 acres in fee and \$5,000 worth of machinery. 7th.—The Calabogie Mine. This property is leased at a royalty of 15 cents per ton on ore sold; \$15,000 worth of machinery. 8th.—The "Blue" Ore Lot, 100 acres in fee. 9th.—The Mississippi Mine covers one square mile, and is leased for 99 years at a royalty of 15 cents per ton on ore mined and sold. There has been 150,000 tons taken from this mine thus far. The plant cost \$20,000. 10th.—The Gildersleeve Mines comprise 1,266 acres in fee and 300 acres in rights. This property contains the celebrated "Flower" mine, which is considered to be the largest mine ever found in Canada. 11th.—The company owns options on some 2,600 acres of mining lands in the townships of Palmerston, Sherbrook, Bahurst, Oso and Alden, costing already some \$10,000, and which can be taken up at a cost of some \$26,000 for the lot, or \$1,000 for 100 acres. 12th.—The "Red Ore" Lot, 100 acres in fee. 13th.—The Black Lake Lot, 100 acres in fee. The manager writes that he has just received the first report of the two cargoes of ore sent to the Joliet Steel Company. He says: "The iron is fully up to our guarantee, and the phosphorus is lower than any ore ever sent to Chicago, '005."

Owing to the increased iron duties Messrs. Cleveland, Brown & Co., one of the largest firms in the Western States, propose opening a branch at London which will give employment to 200 men. Exemption from taxation for ten years is asked.

The *Aylmer Times* states that the copper property owned by Mr. Conroy, near Mattawa, has been sold to an American firm for \$20,000.

PORT ARTHUR DISTRICT.

The main shaft at the Rabbit Mountain Mine has reached a depth of 267 feet. The quantity of silver ore in sight is very encouraging. Considerable improvements have been made. A new compressor house 22x90 two storeys in height, has been erected. In this building are situated the carpenter and blacksmith shops and boiler house. The new compressor machinery and hoist will be brought in as soon as the road leading to the mine is made passable for heavy loads. The capacity of the hoisting apparatus is 250 tons every 24 hours. A new pump has been put in the 250 foot level, which has a capacity of 102 gallons a minute. Other improvements are contemplated.

Some idea of the value and progress made by the various mines in the district may be gathered from the following from the pen of Prof. C. F. Eschweiler in the *Evening Wisconsin*:

"The worst time for the silver district of Port Arthur has passed. The Beaver, Rabbit Mountain and Silver Mountain will dispel all doubt about the paying capacity of these mines. People have forgotten that Silver Islet paid \$600,000 in dividends, besides paying for the mine and the very expensive coffer dam around the shaft. Under ordinary circumstances that mine could have paid about \$2,000,000 in dividends, having 3,500,000 product. The Beaver has all the advantages a mine requires. It has wood and water close at hand, it is kept out of the stock market, and can ship its products at very low rates. Mine and mill are but 2,000 feet apart. The shaft of the Rabbit mine is 260 feet deep, and the vein is getting richer, showing that the silver is not confined to the junction of trap and slate. The Silver Mountain mine seems to promise well. The slate belts of Silver Mountain are underlying those of the slate in which the Rabbit Mountain and the Beaver are finding their silver, because the whole slate formation dips with an angle of about ten degrees towards the coast. Therefore, it is safe to draw the

conclusion that the veins will hold out in depth, if only the proper deposits are worked."

Work at the Beaver mine is being conducted with much vigor. No. 2 shaft has reached a depth of 185 feet, and the quality of the ore is pronounced to be very good.

Manitoba and North-West Territories.

A meeting of the directors of the Canadian Anthracite Coal Company was held during the month at Ottawa. Shipments from the mines are to begin forthwith.

British Columbia.

Latest despatches report that the fund for the relief of the sufferers by the recent calamity at Nanaimo now amounts to \$11,497.75. It is expected that the amount will reach \$25,000.

With a view to securing benefit under the new Act to encourage quartz mining, the B. C. M. & M. Co. have presented to the Government a report on their properties. It is said to be in the highest sense favourable.

New and important discoveries of gold and silver bearing quartz are reported in the Nicola Valley. Prospecting is being pursued with vigor in the district.

The annual meeting of the Vancouver Coal Mining and Land Company (Limited) was held at London on 3rd inst. In moving the adoption of the report the Chairman stated that during the past six months there had been a gross profit of £8,289.10s. £3,554 had been applied to repairs and depreciation, £921 to reserve fund, £1,546 to debenture interest and £744 to London charges, totalling up to £6,709.000 and leaving a net profit of £1,522. The net profit for the previous half year was £2,934. The report was adopted. Messrs. Needham and Trendor were re-elected directors and Messrs. Hill and Lovelock auditors to the corporation.

The *Colonist* announces that rich quartz has been discovered at the forks of Rock Creek in the direction of what is known as Bald Mountain. The surface rock is stated to be very rich, containing free gold. The ledges are wide and the appearance of the country indicates a large quartz belt. The attitude at which the quartz is found is about 3,500 or 5,000 feet above sea level. The quartz is evidently a feeder of Rock Creek, in which stream desultory mining has been carried on for years, and where at one time there was a great placer excitement. Several locations have been made.

We learn that travellers returning from the northern end of Vancouver Island have brought to Victoria rich samples of gold and silver quartz taken from that district.

It is understood that the Island Mountain Quartz Mining and Milling Company have complied with all the requirements of the Act granting bonuses and guarantees to quartz mills, and are now qualified to draw on the Government for the \$20,000 applied for under the Act. The old Kuitz & Lane engines and boilers and the Enterprise Company's stamp mill are in the possession of the company, and will be at once moved to the mill site prepared for them last fall at Jack of Clubs lake, while chlorination for smelting works, whichever is best adapted for treating the ore, will be erected during the summer months. Considerable work has already been done on the ledge by running in tunnels, &c., and it is understood that the

engineer's report to the Government states that there is 10,000 tons of ore in sight. The ledge is of considerable width, and at whatever point it has been struck, assays and mill tests made have resulted highly favourable.

Great Britain.

The peril which in spite of all the preventative efforts of science and legislation ever attends the avocation of the coal miner has received a fresh and terrible illustration by the recent explosion at the Udston Colliery, about two miles from Hamilton in the West of Scotland. This colliery was opened about ten or eleven years ago. The district has an evil reputation in respect of the "fiery" nature of the principal seam worked in it—the well known "splint," and barely ten years have elapsed since the memorable disaster at the Blantyre pits when more than two hundred persons perished. The workings, it would appear, have been carried on in three seams of coal, the "ell," the main and the "splint," the latter at the great depth of nearly 900 feet below the surface. Partly, no doubt, on account of its position the seam gives off a large quantity of gas; but it does not appear that any large accumulation of this dangerous element has ever been observed in the pit, and it is stated that the working regulations have always been stringent and strictly enforced while the arrangements for ventilation and for communication with the surface are in accord with the most modern principles of coal working. The pit is ventilated by a fanner of about 20 feet in diameter, and as the explosion was not so violent as to wreck the apparatus, the volumes of pure air which it drew into the workings neutralised to a large extent the deleterious effects of the gas. Every precaution was taken against explosion. Before the men went down in the morning an inspection of the workings was made in case of "fire," and this had been done as usual. Throughout the mines Scotch gauze safety lamps were used, and no open lights were allowed. Of 74 men and boys in the mine at the time of the accident only two were brought out alive. A thorough investigation is being made as to the cause of the accident, but it seems doubtful whether the most rigid enquiry will be able to throw light on the subject for the lips of those who could have explained it have been closed for ever.

Dominion and Industrial Exhibition.

In the prize list, which has just been issued, for the Dominion Exhibition to be held in conjunction with the Annual Exhibition of the Industrial Exhibition Association, at Toronto, from the 5th to 17th September next, the following prizes will be awarded exhibitors in class 85:—

ECONOMIC MINERALS AND ORES OF CANADA.

SEC.

1. Salt, crude. Bronze Medal
2. Salt, dairy (judges to test for impurities) Silver Medal

- | | |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| 3. Salt, table (judges to test for impurities)..... | Silver Medal |
| 4. Ochres and other mineral paints, best collection of..... | Diploma |
| 5. Gypsum, best collection, crude and calcined..... | Bronze Medal |
| 6. Marbles and Lithographic Stones best collection of..... | Silver Medal |
| 7. Phosphate of Lime, and its manufactures, not less than 50 lbs., each, well displayed..... | Silver Medal |
| 8. Clays and Sands for pottery, moulding and glass-making, collection of..... | Bronze Medal |
| 9. Cements, best assortment of, for building purposes, exhibitors to be present with the judges to have tests made..... | Silver Medal |
| 10. Asbestos and its manufactures, if exhibit is worthy..... | \$10 |
| 11. Mica, in mass and sheets, labelled with locality where found..... | 10
1st 2nd |
| 12. Iron Ores, large specimens, Diploma and..... | \$10 \$5 |
| 13. Copper Ores, large specimens, Diploma and..... | 10 5 |
| 14. Gold and Silver Ores, Diploma and..... | 10 5 |
| 15. Lead Ores, large specimens, Diploma and..... | 5 3 |
| 16. Plumbago and its manufactures, large specimens, Diploma and..... | 10 5 |
| 17. Best collection of Mineral and Geological specimens, properly classified and described, of which one-fourth at least have not been previously exhibited here..... | 10 5 |
| 18. Best collection of Mineral and Geological specimens, as in Sec. 17, by students under 18 years of age..... | 8 5 |
| 19. Best Archæological collection. { | 1. Dominion Gold Medal
2. Silver Medal |
| 20. Extra Entries. | |

The entrance fee is 25 cents. Any of our readers who may desire a copy of the complete Prize List can obtain one by communicating with Mr. H. J. Hill, the secretary, Toronto.

At a recent meeting of the Berlin Physical Society, Dr. Gross explained his theoretical view on the heat of solution of magnetised iron, and showed why, in accordance with these, the heat of solution of magnetised iron must be greater than that of unmagnetised. One result of these views was that a piece of magnetised and unmagnetised iron in a conducting fluid capable of dissolving the iron must give a current; this he has already demonstrated two years ago. The current in such an element as this flows across the fluid from the magnetised to the unmagnetised pole, and is independent of the nature of the magnetisation. The source of the electric current is in this case, according to the views of the speaker, to be sought for in the loss of specific magnetisation which the molecules of iron undergo as they pass, from the solid to the fluid condition. Of the various solutions of salts of iron which were used in these experiments, only neutral salts of ferrous oxide were found to yield a result, while the salts of ferrous oxide gave no current. The cause of this is, according to the speaker, that only the ferric salts lead to a solution of the magnets. *Nature* says: "Dr. Nichols has quite recently carried on some experiments on the heat of solution of magnetised iron, and has obtained the same experimental results—namely, that the heat of solution of magnetised iron is greater than that of unmagnetised, although he starts with theoretical views respecting the magnetic potential of solid iron and iron in solution which are diametrically opposed to those of Dr. Gross."

Ottawa Field Naturalist Club.

Notes on the Utica and Trenton Formations at New Edinburgh.

By. H. M. Ami, M.A., F.G.S.

Ever since the opening of the collecting season this year there have been ample opportunities afforded the members of the Ottawa Field Naturalist Club and others interested in the science of geology to examine a number of interesting exposures about Ottawa, and not a few have availed themselves of this opportunity. Foremost among the numerous sections observed in the series of Cambro-Silurian rocks are those which may still be visited in New Edinburgh, along Creighton street. Since the addition of the vice-regal suburb to the city, Engineer Surtees has been busily engaged carrying on excavations for waterworks purposes in this new ward, and as New Edinburgh is for the most part built immediately upon the Trenton and Utica formations, which are overlaid by exceedingly thin and for a considerable extent by our Post-Tertiary deposits, such as drift clay, sand and the like—there is a considerable amount of blasting to be done.

The highly fossiliferous measures of the Utica, resting immediately and conformably upon these of the Trenton, may be well seen on Creighton street. The contact of the two formations occurs near the northern end of this street, and the Trenton strata occurring then at the northern extremity of the street, show clearly the transitional character of this series of strata.

The Trenton here consists chiefly in dark grey or black bituminous limestones, for the most part nodular and holding such characteristic form, viz:—*Murchisonia*, *bellicincta*, *Hall*, *Trochomena*, *mubilitatum*, *Hall*, *leptaena*, *Sericea testudinaria*, and the *Strophomena Alternata*.

Before crossing Union street, nearly 100 yards from that street, the Utica is well seen and such well-known and characteristic forms as *Asaphus Canadensis* indicate the horizon of the rocks. No less than thirty species of fossils have already been obtained from the measures of the Utica in New Edinburgh, and no doubt more will be found when careful collecting has been made and when the material obtained shall have been examined.

A special interest attaches itself to the rock which confines the measure of this formation. They are for the most part highly bituminous, and when distilled can be made to yield a highly inflammable substance which belongs to the *petroleum* group. The shales of Windsor, Ont., a village near Collingwood, have yielded bitumen, and *coal oil* was obtained from those shales. The percentage of this useful material in the shales, however, is not such as would warrant their being distilled for oil. The operations at Windsor being leased where the abundant supplies from the Devonian shales of the Essex peninsula in Western Ontario and elsewhere was discovered. The bituminous character of the rocks of the Utica formation is no doubt due to the presence in vast numbers of the remains of trilobites, and such forms of by-gone life.

FOR SALE.

Lots 25, 26, 27 and 29 in the 3rd range. Some excellent surface shows have been uncovered on these lots and only require capital for developing. Price and particulars given at the office of the MINING REVIEW.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should any person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:— "Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR

Notice to Contractors.

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Superintendent's Residence at Experimental Farm, near Ottawa, Ont.," will be received until FRIDAY, 24th June next, for the several works required in the erection and completion of the

SUPERINTENDENT'S RESIDENCE AT EXPERIMENTAL FARM, NEAR OTTAWA, ONT.,

Plans and specifications can be seen at the Department of Public Works, Ottawa, on and after Friday, the 10th June next.

Intending contractors should personally visit the site and make themselves fully cognizant of the work to be done, according to the said plans and specifications, before putting in their tenders.

Persons tendering are further notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted bank cheque made payable to the order of the Honourable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party decline to enter into a contract when called upon to do so, or if he fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department will not be bound to accept the lowest or any tender.

By order, A. GOBEL, Secretary.

Department of Public Works, }
Ottawa, June 2nd, 1887. }

MAIL CONTRACT.

SEALED TENDERS addressed to the Postmaster General will be received at Ottawa until noon on FRIDAY, 5th August, 1887, for the conveyance of Her Majesty's Mails, on a proposed Contract for four years, six times per week each way, between

METCALFE
AND
OTTAWA,

from the 1st September next.

Printed notices containing further information as to conditions of proposed contract may be seen and blank forms of Tender may be obtained at the Post Offices of Greely, Leitrim, Billings Bridge, South Gloucester, Ottawa, and at this office,

T. P. FRENCH,
Post Office Inspector.

Department of Inland Revenue.

An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

OFFICE:

UNION CHAMBERS, 14 Metcalfe St.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 17th of the month.

Address all correspondence, &c., to the Publishers of the CANADIAN MINING REVIEW, Ottawa.

Advertising Space.

The circulation of the CANADIAN MINING REVIEW, which has steadily been going up since its first publication, more than five years ago, has now more than doubled the estimate upon which we had reckoned, and its value as an advertising medium to business men who wish to reach the best classes of mine owners and operators, and the mining centres and camps of every province in the Dominion, is consequently very greatly enhanced. The REVIEW is in the widest sense a Canadian journal belonging to all provinces alike; it is the only journal published in Canada wholly devoted to the interests of her mining industries and mineral resources. We would simply draw the attention of those who have hitherto overlooked it, to this matter, promising our best attention and most reasonable terms on any application for advertising space.

Mining Engineers and their Responsibilities.

The grave want of common carefulness, worse still, the gross carelessness and in some instances even unscrupulous lying that is sometimes to be found in publications and reports circulated in connection with contemplated mining enterprises has been strongly deprecated in these columns. It is not the practice of vendors of mining properties to under-estimate the value of their possessions when seeking to attract the pockets of capitalists; and this is all the more reason why extra care and precaution should be taken by our mining engineers of repute, to whom is entrusted the examination of and reporting on mining properties, or the responsible task of verifying or otherwise the generally exaggerated statements made by or on behalf of the vendors.

This is very well pointed out in a recent issue of an English contemporary, which says:—

“Events which have occurred in connection with recent attempts to float rather pretentious mining undertakings afford the most complete evidence that if this legitimate class of industrial enterprise is to retain its favour with British capitalists some more reliable system must be adopted to ensure greater correctness in the reports published in prospectuses which set forth the value of a property and its probable return. The experts, so called, who are employed to place an approximate value upon mining property have, undoubtedly, a difficult task to perform, and we, who are acquainted with gentlemen of vast mining acquirements and experience in all parts of the world, are aware how earnestly many labour to discharge their duties in the face of many difficulties, and often of many temptations. It is true that many a man, however exact and conscientious he may be, may fall into error, and in such a case every allowance must be made; and generally is made, for any consequences which may result from lack of discretion. But recently a practice has crept in in connection with the examination of and reporting on mines, which is in every way reprehensible, not to use a stronger word. Recent events have shewn that almost culpable negligence or carelessness of the grossest kind has been displayed by mining engineers in connection with mining properties on which they have furnished reports. Examinations of the properties, if they have been made at all, seem to have been made in the most superficial and perfunctory manner. In all cases an investor, to whatever kind of undertaking he inclines, must largely rely on the judgment of others regarding the value and probable prospects of any particular property; but if this be so in regard to almost every kind of industrial undertaking, still more is it so in regard to a mining enterprise, because not only are the properties, as a rule, situated a long way off, but the whole details of management are of so intricate and technical a nature that entire reliance must be placed on those who are, or who profess to be, experts in these matters. Those who are interested in mining and who believe as we do, that it is a legitimate and often enormously profitable means of employing money, should insist that any laxity in connection with the all-important point of thorough initial investigation of mining properties, will be held to entail grave responsibilities on the part of those who profess to speak authoritatively, on that which they barely know little or nothing.”

The history of several Canadian mining enterprises points out in no unmistakable manner how lamentable has been the loss of capital for lack of that careful preliminary inspection and investigation which should be made into the capabilities of every mining property before the public are invited to invest their capital.

A Commendable Enterprise.

Mr. Kamper, who was recently in Ottawa negotiating for the purchase of the Inter-Colonial Railway to a German Syndicate, states that a part of the contemplated scheme is to open up and operate immense iron works at or near Pictou. He says:—

“Our company has already spent some money in having an examination and report made of the iron resources in Nova Scotia by a staff of German engineers, and their report was so flattering that the company decided to open up immense iron and smelting works near Pictou, provided the Canadian Government would give us protection for a certain number of years to enable us to cope with American and European iron manufacturers. If this protection can be obtained we will at once commence the construction of immense works near Pictou, and will immediately bring out from Germany 1,000 skilled iron workers to introduce the German methods of working iron in Canada. We have also a very high opinion of the great mineral resources of Nova Scotia, and are satisfied that if worked according to German methods, and with sufficient capital, they would turn out results that would astonish Canadians.”

The Government will no doubt see to it that these experienced Germans get every encouragement within reasonable limits. Their enterprise, if carried through to a successful issue, cannot fail to build up, on a modern and

practical basis, our iron industry in the Maritime Province.

We note that the Hon. Mr. Mowat has gone to England. While there the Ontario premier might make a careful study of British mining laws to the advantage of his Commissioner of Lands and Forests. A reservation of Ontario's mineral resources for the benefit of the mining community is badly wanted at present. Unfortunately as matters exist too much provision is made for speculators, farmers, cattle dealers and other slaughterers of the mining industry.

The following official figures are given to indicate the quantity of Anthracite and Bituminous coal shipped to Canada from the United States during the past fiscal year:—

The Sudbury Copper Mines.

In an interview with Dr. R. Bell, Assistant Director of the Geological Survey, we gathered the following interesting notes on the above mines. Dr. Bell said in substance: Any information which I can give refers principally to the condition of these mines in January last, when I paid them a short visit, for although I was again at Sudbury in the end of May, I did not then re-examine the works. A considerable village is springing up at Sudbury, which is favourably situated at the junction of the Algoma branch with the main line of the Canadian Pacific Railway. Two places are being worked—one called the Copper Cliff Mine, five miles south-south-west of the village, and the other, called Stobie Mine, four miles north of it. At the first of them the ore was found in the face of a cliff of diorite forty or fifty feet high, and the deposit had been worked from the base of the cliff to a depth of forty or fifty feet, giving a total of eighty or ninety feet at the time of my visit. The shaft or elongated pit showed a vein of solid copper pyrites ten feet or more in width. Splendid masses of yellow pyrites were being taken out. A large quantity of ore was piled up for spauling previous to shipment. A spur track from the Algoma branch has been built to the very mouth of the shaft, so that there is every facility for sending off the ore. Mr. L.H. Ashmun, the general superintendent of the mines, informed me that before winter set in they had shipped some sixty-seven car loads, or between 3,000 and 4,000 tons from this mine to the smelting works at Bergin Point, near New York. Some of it contained as much as 18 per cent. of copper. The percentage of any particular lot depended on the care and labour which had been bestowed on dressing it up by

spauling and caving. The solid pyrites showed different shades of yellow in streaks and patches, according to the proportions of copper and iron combined with the sulphur. I understand that the shaft is now about twice as deep as when I saw it. The works at the Copper Cliff are under the intelligent management of Captain Samuel Hosking.

The Stobie Mine, four miles north of the village, had only been prospected up to January, but since that time, mining has been actively carried on. A branch railway from the junction was then almost completed, and is now in operation. As the ground was covered with snow I could not make a very thorough examination of the deposit at this locality, but from the information given me it must be of great extent. I was told by the superintendent that by costeeing they had ascertained the existence of a mass of ore measuring on the surface 1600 feet from north to south, and 1200 feet from east to west. It is in the form of a wide round hill, covered like the surrounding region with naked, burnt trees, and in appearance it does not differ in any way from the other low hills around. In digging through the surface, however, in any part of this hill, the subsoil is found to consist of red ochre, resulting from the burning of the oxide of iron, left by the decomposing ore. Below this are crusts of iron oxide like bog ore, and under them is a layer of black half-decomposed pyrites, which gradually passes into the solid sulphides of copper and iron. The two sulphides are mixed in a mottled and spotted form in various proportions. At the time of my visit they were putting up the machinery for driving an adit under the hill from the low ground on the east side. Since that time I hear that considerable progress has been made in this work. A deposit of such great extent is, of course, capable of furnishing an immense supply of ore and I have lately been told that the proprietors have contracted to furnish over 30,000 tons within the next year.

In addition to the two places which are being worked, promising deposits of copper ore have been found at a number of localities in various directions in the neighborhood. The original discovery of copper which led to the finding of all the others was made in a cutting on the main line of the railway a short distance west of the junction, but this place has not been worked. Judging from present appearances Sudbury promises to become a great centre of copper mining. The accidental discovery of copper at this place serves to indicate what great mineral wealth remains to be found in some of the more promising, but yet unexplored regions of the Dominion.

Geologically the Sudbury copper deposits occur in the Huronian rocks, near the southeastern edge of the great belt which extends north-eastward from Lake Huron to Lake Abitibi and beyond. More than thirty years ago, copper and iron pyrites, rich in nickel, was found on the north shore of Lake Huron at what was called the Wallace Mine. This is in the same geological horizon as the Sudbury Mines. I have examined the mine and the ore has a considerable resemblance to that of Sudbury, which also contains considerable nickel. Copper has been found in several places between the Wallace Mine and Sudbury, and also in the continuation of the strike to the north—eastward—on Tanagama Lake, for example, and again on the Blanche River, further on in the same direction. A belt of Huronian rocks, connected with the one already referred to, runs eastward from near Lake Abitibi to the south end of Lake Mistassini and on the south side

of this belt near the latter lake, a notable deposit of copper pyrites was found by the late Mr. Richardson, of the Geological Survey, many years ago. It would be interesting to have this ore analysed to ascertain if it also contained nickel. If it does, it would always be an additional fact in identifying this horizon, and would go to show that we have an important copper-bearing belt of rocks extending all the way from Lake Huron to Lake Mistassini, a distance of some 500 miles or greater than that from Toronto to Quebec.

Copper may also be looked for in a corresponding position on the opposite, or north-western side of the great Huronian belt I have referred to, and in this connection I am reminded of an interesting fact, namely, that in 1875 I discovered a vein worth noting on account of its size and the quantity of copper pyrites which it contained, on the east branch of the Montreal River, which apparently corresponds in geological position with the Sudbury deposits, but on the opposite side of the trough. It is mentioned in my report to Government of that year.

I regard the whole region around the Montreal River as a very promising one for economic minerals, and I am about to explore it geologically this summer.

Our Mines and Minerals.

W. A. Carlyle, Montreal.

Continued from June issue.

Canada is becoming more noted for her extensive and valuable mines of minerals, popularly known, such as apatite or phosphate, graphite or plumbago, asbestos, gypsum, mica, slate, marble, oil and salt. Day by day the value and utility of minerals long neglected and passed by, become more evident and new industries are springing up to convert the unsuspecting, seemingly useless rock into a commodity of commercial importance. It is well known that there are large deposits of graphite as pure as those of Ceylon or Siberia, only their proper development awaits the change of events and the removal of old country prejudices. The great European manufacturers, at Falor, have become so familiar with the graphite of the east or of Russia, that they will not deign to look at ore from new localities. From the mines at Grenville and Buckingham are got pure blocks of graphite weighing from 700 to 4,000 lbs. each.

Among the mining industries of importance none have grown so rapidly or promise greater returns in the future than the mining of phosphates of lime or apatite, which is found in great abundance in the Laurentians of the Ottawa Valley, at Templeton, Buckingham, Wakeland and Portland. With the advent of more capital and better means of access, these mines are being opened up in a proper and systematic manner, working summer and winter, and last year 20,000 tons, worth \$550,000, were shipped from Montreal to England and Germany. This phosphate, declared by an agent of the U. S. Government in his official report as apparently inexhaustible in volume, and the finest known in the world as a phos-

phate fertilizer, sells readily at this port at \$18.20 a ton.

In Western Ontario, near Goderich, are the famous salt beds, famous for their great thickness and purity of the rock salt. These beds, aggregating 128 feet in thickness of pure salt, are found at a depth of 1,500 feet, and from them brine is pumped up and concentrated. Dr. Sterry Hunt has estimated that these deposits will yield 880,000 bushels of salt per acre of area. In 1873 the yield amounted to 4,520,000 barrels, while since then the increase has been very great.

Not very far from here, at Petrolia, are the great oil wells of petroleum, a most valuable economic mineral. The wells are bored to a small depth, 500 feet, and now number 2,700, and during the past four years they have produced 6,000,000 barrels of crude petroleum annually.

Throughout the broad lands of our Dominion are scattered very great coal fields, aggregating 97,000 square miles, and containing at a low estimate 100,000,000,000 tons of coal. The collieries of the Maritime Provinces have long been well known, and now the coal beds of the North-West are arousing the keenest interest, as the presence of extensive beds of good coal in these great woodless tracts is imperative for the very existence of the tide of people now settling these new provinces. There is no coal in Ontario or Quebec. On the Pacific coast inferior beds of hard coal are on the Queen Charlotte Islands, while on Vancouver Island are the most productive mines west of the Rockies. In 1885 the collieries at Wellington and Nanaimo produced 360,000 tons of excellent coal, which was shipped to San Francisco, Honolulu, or consumed in British Columbia. The character of the coal in the North-West varies greatly, changing from a poor, watery lignite to good hard coal. Just east of the mountains, in the district of Alberta, are the brightest indications, as through the valleys of the Bow and Belly rivers along the foot of the Rockies, extend great coal beds that will yield from 4,000,000 to 9,000,000 tons per square mile, one seam alone, the "coal bank," containing 330,000,000 tons. The coal is similar to that mined in the Western States for the Union Pacific railway, and is much superior to most of the lignites and brown coals which give rise to important industries in various parts of Europe. This area has crossed beyond the first range of mountains, and at Banff, now becoming familiar to tourists and invalids, the coal is found altered to beds of anthracite that will compare favorably with some of the best beds in Pennsylvania. These coal fields are very easy of access, and already some are being extensively mined to supply the demands of the C. P. R., and of the people. Great lignitic coal beds have been discovered along the valleys of the Saskatchewan and the Souris rivers, and in many other districts; and it would seem as if Dame Nature had carefully hoarded up great

stores of light and heat for the people who will yet inhabit the vast prairies and valleys of this great territory.

In New Brunswick there is an area of coal containing 150,000,000 tons, but Nova Scotia boasts of the best Canadian collieries. In this province are three distinct coal basins, Cape Breton, Pictou and Cumberland, where many of the seams have a notable thickness of 25 feet to 58 feet. The coal is well suited for heating and illuminating, as well as for iron smelting, and is now exported in large quantities. The Sydney mine in Cape Breton was begun in 1785 and has since been in constant operation, yielding in 1885 over 150,000 tons. The Springhill mine in 12 years has produced 1,700,000 tons, while in 1884 the Intercolonial mines produced 120,000 tons, the Acadia mines 115,000, the Albion mines 200,000, and the Vale colliery 74,000 tons of coal. During the past year of 1886 1,430,000 tons of coal have been shipped from Nova Scotia, which will give some idea of the extent of coal mining in this part of Canada.

In 1850, by the bursting of a dam in Albert County, New Brunswick, a vein of black jet-like mineral* was exposed. It was not coal, but as an enricher of coal-gas. This vein, the only known one in the world, brought nearly \$1,000,000 to the fortunate possessors.

Canada may be justly proud of her coal measures, as these great deposits must yet play an important part in the political economy of this nation, as it is such stores of wealth that strengthen a nation's power and influence the industries and fortunes of her people.

The wealth of copper hidden away in our mountains, especially along the shores of Lake Huron and Lake Superior and near Lake Nipissing is evidently great. This district has been most favourable for the accumulation of iron, silver, copper and gold, as in the valleys or troughs of the Laurentians are the rocks of the Huronian Formation, which have been fearfully twisted and distorted, while there have been great out-pourings of volcanic matter. These great earth movements have left many gaping fissures which have since been filled up with quartz and mineral ores out of the surrounding rocks by the heated waters percolating through them, and in the same vein may be found, all mixed together, arsenic, sulphur, iron, zinc, lead, copper, silver and gold.

Loose copper has been found in British Columbia, and the Coast Indians have used from time immemorial copper brought from the Alaska rivers, which they claim can be found in great abundance. Mining in the Lake Superior district has, for the most part, been suspended, though the most extensive Canadian Copper mines have been developed here. The West Canada Mining Company owned the three most valuable properties, the Bruce, Wellington and Huron Copper Bay mines, of which the Bruce mines were opened in 1846. The veins were large and rich, and most of the

ore was shipped to England, after having been dressed so as to yield 20 per cent. of pure copper. In 1875 the works were abandoned owing to the caving in of the richest part of the mine, and the great fall in the price of copper after yielding \$3,300,000 worth of metal. Last summer great reports were circulated about the unusual richness of the copper deposits at the Sudbury mines, which are situated near the Canadian Pacific Railway, north of the Bruce mines and west of Lake Nipissing. It is quite possible that beds of exceptional richness may occur there, still these mines, it is now believed, are not at all phenomenal in their extent and value, though the results of this winter's work, where a large number of men is being employed, will give more correct and reliable information. ✕

At present, a copper mine to be paying, must possess exceptional facilities and richness, as in the United States and Europe. such a vast amount of copper is being mined so cheaply as to make this industry with difficulty profitable. In the State of Wisconsin there are copper beds which yield masses of pure metal weighing 100 tons; and in 1882 two mines, the Hecla and Calumet, produced 16,000 tons of copper. In Australia are great veins of pure ore, 80 feet to like jet or asphaltum and proving very valuable 100 feet thick; and in Spain, Hungary and Germany are beds of enormous extent which can be mined very cheaply. With this great competition and the want of proper fuel, Canadian copper mining has been necessarily limited to the most favored areas. At Ascot, in Quebec, are very good mines. From the Crown mines 18,000 tons of ore are being annually shipped to the United States. The Albert mine, 600 feet deep, is producing 25,000 per year, while the Hartford shaft, now closed, can produce 1,000 monthly. The Harvey Hill mines, near Leeds, were worked for a long time but finally closed in 1879. Good deposits are known in New Brunswick, Newfoundland, and Nova Scotia. At Coxheath, Cape Breton, operations of an extensive and successful character are being energetically carried on. Careful trials have been made by an expert mining engineer, who has reported that considering the price of fuel, plus labor, smelting can be done at this mine more cheaply than at any mine in the United States, and probably cheaper than at the extensive works of America or Europe. Thus the prospects of prosperous and extensive copper mining and smelting in this part of Canada are now very encouraging. New companies with large capital are being formed to mine the deposits north of Lakes Huron and Superior, and with better and cheaper processes, introduced during late years, this district may again soon flourish with this reviving industry.

The most important gold regions of Canada are in British Columbia, Quebec and Nova Scotia, while the precious metal has been found in the region of the Lake of the Woods and

Lake Superior, in veins associated with ores of copper, lead and silver. In British Columbia gold is very generally distributed, but the richest fields follow a region of mountains and high plateaux, comprising the Purcell, Gold and Cariboo ranges. Gold is said to have been first discovered near the junction of the Fraser and Thompson rivers, and in 1858, ten years after the great California rush of '49, miners began to flock in, and the gullies and flats of the Fraser became animated with men eagerly searching for the yellow metal. The gold has been mostly obtained by washing the placer deposits, and in 1860 the Cariboo district, the richest of all the Columbian diggings, was first worked. In 1869 Ominica was developed, Kootanie in 1886, while in 1886 occurred the rush to the Big Bend of the Columbia river. The total yield of the gold from this province up to 1886 amounted to \$49,000,000 worth of bullion, of which Cariboo gave nearly \$20,000,000. When compared with Australia or California, these gold diggings have not proved so very rich, for in one province alone of Australia, Victoria, during the same period of time, \$1,000,000,000 worth of gold has been mined. At present the surface deposits appear to have become quite impoverished, except at Cariboo and Granite Creek, and prospectors have been attracted to the gold bearing veins which a year ago promised remarkable results, but during the past year of 1886 these hopes have been greatly crushed, as many leads which seemed so promising have been found worthless, except with the expenditure of an immense amount of capital. The piercing of the canyons and heights of the Rockies by the Canadian Pacific Railway, now offers better means of access for the heavy machinery necessary, but even yet the cost and trouble of transportation is so great that capitalists cannot be induced to develop these gold veins until they know the results of one large company, which has begun operations on an extensive scale. Still, judging from present authentic information, British Columbia will not be a rich source of gold unless it is found in greater quantity and under more favorable auspices, and those who have foretold the flow of a golden tide from these mines of the Pacific, are doomed to disappointment, or a long waiting for the realization of their prophecies.

The occurrence of gold in the Chaudière Valley, in Quebec, was first noticed in 1835, after which it was seen that nearly every stream would yield gold when the sands were washed. In the Counties of Compton and Beauce, paying deposits have been worked, while mining on the little Ditton River, carried on in a most desultory and primitive manner, has yielded \$100,000. Throughout the Chaudière Valley there are many gold bearing veins, while many feet below the present river, are ancient river channels, which, when reached, have proved to be very rich in coarse gold, and will, without doubt, in the near future, make this valley one of the richest mining districts of Canada. Gol

*Albertainite.

was first discovered in Nova Scotia in 1859, and in 1862, 7,000 ounces were extracted, since then the yield has been high, 400,000 ounces, worth \$8,000,000, having been mined. When it was announced that gold was being found in many places, men and capital poured in, but through reckless and ill-advised systems of mining, failures thickened everywhere. The gold bearing area, 100,000 square miles in extent, reaches from Canso to Yarmouth. The pressure of the ocean bed, as mentioned before, has caused tremendous foldings of the earth throughout this part of Canada, twisting and bending great areas of rock as if so much paper, and great stretches of land have been folded together and thrown completely over. On the summit of these great folds, which have subsequently been greatly worn away by the high action of water, are found the richest veins. The most successful results so far have been attained by small companies, as large corporations with large expenditures have generally met with failure. Indications warrant the expectation that with better experience and skill, these regions, which are certainly rich in gold, will yet become of much greater value and importance.

Silver has been mined in British Columbia, but the chief and most celebrated mines are along the shores of Lake Superior, whither attention was drawn in 1846 by the discovery of silver and copper in the sandstones and limestones. A few companies worked some of these veins for a time, but nothing of much value was done until 1863, when rich discoveries at Thunder Bay again aroused great interest among miners, who met with very discouraging results. In 1868 the Montreal Mining Company sent out a large party under Mr. Thomas McFarlane to survey and examine this wilderness of rock and forest. Many veins of silver and copper were found, and one day, while an assistant was planting his picket for the surveyor on a small rock three-quarters of a mile from the main bend, he noticed a vein rich in lead ore. On blasting near the water's edge rich nuggets of silver were found, and on looking down through the clear crystal waters of this lake, the excited explorers could trace a large vein running far out into the water; detaching and fishing up blocks of the rock, they were found to be rich in lead, while further examination disclosed the great wealth of silver and the most famous silver mine in Canada, Silver Islet, gave up the secret of its hidden treasure. Silver Islet was a small island only 40 feet across at its greatest width, being the summit of the hard quartz vein just appearing above the water, and before operations could be begun, it was necessary to build up all around to keep out the water and to make room for the mills and wharves. This was a source of great trouble, as the island being only 8 feet above the lake, was exposed to the full fury of the gales and the force of the moving ice, which again and again crushed in the crib-work though

it was massively built. Between the years 1870 and 1878 \$3,000,000 worth of silver was sold, and up to 1884, when work was suspended at a depth of 1,230 feet, \$6,500,000 had been extracted from this mine, which ranks among the famous mines of the world.

This closes a rapid and very imperfect summary of the mines of this Dominion. The endeavour has been made to give a few facts about these metal industries, with their present condition and future prospects, as well as the factors or influences which affect and control their destinies. Canadian capitalists, taught by experience, or rather the fruits of inexperience, and the many failures, have become exceedingly wary when allured by tempting offers of mines fabulously rich, and many really valuable and safe properties now remain idle which would yield fortunes if judiciously and sensibly managed. Among the world's industries, none, perhaps, is so uncertain, so liable to failure as that of mining, as there are so many elements of failure with which to contend; and many unsuccessful ventures have been ruined by sheer hard luck.

A traveller through the mining districts of Colorado will see the waste of millions of money scattered through the canyons and along the hillsides, with nothing left to account for the vanished wealth but buildings of useless machinery and a hole in the ground. Such can be seen in Canada. Along the shores of the Lake of the Woods stand monuments to the folly of inexperienced men, who, believing they had found wealth untold, rushed in with machinery and mining appliances worth many thousands of dollars, which any engineer, or anyone familiar with mining, would have at once told were totally unsuitable for their particular kind of ore. Is it any wonder then that these men did not realize their golden dreams, and that now all these valuable mills stand idle and valueless, with the capital all dissipated. This has been the great cause of mining failures in Canada and elsewhere. Companies, instead of securing competent and expert advisers and spending several thousands of dollars in learning the real extent and value of their property, have gone on with their work, trusting to their own judgment and imperfect knowledge, believing that a certain system of mining, successful in another locality, will exactly suit their own, a fallacy to which many a ruined man will attest.

For all this Canadian mines offer many incentives to the miner. This part of her great natural resources will certainly be a valuable and most important factor in her future destiny, and will aid, greatly, in making her the great nation she promises to become.

A British government blue-book has been issued, containing detailed reports relating to the ownership in minerals and mining rents and royalties in France, Germany, Austria-Hungary, Italy, Belgium, Portugal, Spain, Sweden and Norway, and the United States.

Use of the Magnetic Needle in Exploring for Iron Ore.

By Mr. B. H. Brough, Assoc. R.S.M., F.G.S., F.I.C.

[Reproduced, by permission of the author, from a paper submitted to the Iron and Steel Institute, Lon. Eng.]

As a general rule, geological and mineralogical methods alone are used in exploring for ore deposits; only in a few exceptional cases are physical methods possible. Thus in exploring for magnetic iron ores the compass may afford valuable aid, and has, in fact, been employed for this purpose in Sweden and the United States for many years.

The theory of its use is based upon the fact that certain minerals deposited in the earth become magnetic by induction under the influence of the earth's magnetism, and that, consequently, the two poles are fixed in the direction of the magnetic inclination at the opposite ends of the deposit. It is well known that there are substances, such as steel and magnetite, exhibiting polar magnetism: that is to say, they retain the magnetism once acquired even if the inducing force ceases to act. Other substances, such as soft iron and magnetic pyrites, exhibit simple magnetism; in other words, they are magnetic only so long as the induction remains.

The intensity of the magnetism exhibited by deposits of magnetite varies greatly, and is frequently so slight that only delicate instruments and practised observers can detect it; in other cases the needle is affected at considerable distances. It must, of course, be remembered that a given magnetic force affects the needle to exactly the same degree through 100 feet of granite as through the same distance of air.

If the magnetic north pole of the earth is regarded as negative, and the south pole as positive (in the northern hemisphere), the upper end of a vertical mass of ore will be negative, and the lower end positive. Consequently, if a magnetic needle is brought near the upper or negative pole of the deposit, the north-seeking or positive end of the needle will be attracted. When the point of observation is very near the ore-pole the needle will dip downwards. The lower or positive pole of the ore-mass, being usually situated at a considerable depth, will not affect the observation. Other deposits, coursing in a more or less easterly and westerly direction, are less affected by induction; the poles being situated in the long sides of the deposit. Frequently the deposits are faulted and broken. In this case the separate portions behave like fragments of a broken bar magnet, the adjacent ends exhibiting opposite polarity. In exploring for ore, then, if, on advancing from north to south, the free needle is first attracted and then repelled, a fault in the deposit is indicated.

To explore for ore the ordinary miner's dial or surveyor's circumferenter may be employed. If a straight line is followed with the instrument, the needle will remain directed towards the same point of the dial; or, in other words, will remain in the magnetic meridian as long as it is kept sufficiently far away from iron and magnetic ore masses. But if these are approached, the needle will gradually be deflected. The only case in which there will be no deflection is when the attracting deposit is approached along the meridian passing over its upper pole. It follows that in magnetic surveys the meridian line must be found, and fixed in the field or on the plan. For this purpose at least two straight lines are set out in the magnetic east and west direction, from thirty to fifty yards apart. These lines will at

some point cross the meridian line. If the dial is set up at one end of a line of this kind, at a considerable distance from the magnetic mass, there will, of course, be no attraction. On approaching the meridian the needle will be gradually attracted, and at a certain distance the maximum attraction will be reached. On approaching nearer it will become smaller, until, at the ore meridian itself, it will be inappreciable. The angles of deflection observed at the various stations are noted on pegs driven into the ground, and also in the field-book, or in the plan. Following the same straight line to the other side of the zero point—or, what is the same thing, to the other side of the ore meridian—the same attractions are exhibited, but in reverse order; the needle turning back to the meridian. If similar observations are made along the second east and west line it is easy to fix the ore meridian by joining the two points where there is no deflection. These points are midway between the two points of maximum deflection. This passes over the upper pole of the deposit, and if the pole is approached along the meridian line the dip of the north-seeking end of the needle will, as a rule, be greater the nearer it comes to the pole. This method is, however, not adapted for fixing the position of the pole exactly. This may be done by determining the isogonic lines—that is to say, by joining the points where the needle has the same deflection.

In order to obtain one or more parallel isogonic lines on both sides of the ore meridian, it is necessary to set out a number of lines parallel to the ore meridian, and from ten to thirty yards apart. At the points where these lines intersect the east and west lines, the angles of deflection must be observed, and isogonic lines constructed by joining the points of equal deflection. The needle being drawn so much out of its horizontal position that its free play is hindered, it must be weighted and balanced by a piece of wax. If, now, from some point of intersection in the network of squares made on the field of observation, a line is drawn in the direction of the deflection of the magnetic needle, it will cut the isogonic curve at a second point, and, eventually, the ore meridian. The two points where the isogonic line is cut are joined; the joining line is bisected, and at the point of bisection a perpendicular is erected; then, perpendicularly under the point where this cuts the meridian, is the upper ore pole, and at this point it will eventually be found best to sink the shaft, so as to be certain of cutting the ore mass. The ore meridian, it must be noted, need not always be a straight line.

In cases where a better instrument was not available, excellent results have, in this way, been obtained with the ordinary pocket box compass, held in the hand.

For preliminary magnetic surveys, no instrument is better than the Swedish compass. In this instrument, the needle, besides revolving in a horizontal plane in the usual manner, can also turn in a vertical plane to an angle of about 60° with the horizon. The needle is horizontally suspended in a brass case on a long vertical brass pin by means of a long glass cap. The brass terminates above in a short steel point, on which the glass cap rotates. At the bottom of this is a brass stirrup, provided with fine holes, through which pass the horizontal pins supporting the needle. To enable the needle to dip, there is a long slot cut along the middle of it. The compass box can be suspended by means of three strings passing through three small rings fastened 120° apart on the outside of the box. It can thus be easily carried in the hand.

Graduation is not usual, and indeed unnecessary. Only the cardinal points are marked, as in using it, deviations from the horizontal position alone have to be noticed. This compass was invented in the last century by the celebrated Swedish miner, Daniel Tilas, and is still in general use. The dip of the needle is estimated merely by the eye, and is not actually measured.

The miner's or dip compass was invented in the United States in 1866, and was adopted by the Geological Survey of New Jersey in the systematic explorations for magnetic iron ore in that State. In this instrument the magnetic needle is suspended so as to move readily in a vertical direction; the angle of inclination being measured upon the divided rim of a small compass box. The needle cannot move horizontally. When in use, the ring is held in the hand, and the compass box, by its own weight, takes a vertical position. It must, of course, be held in the plane of the magnetic meridian, which can be determined by holding the instrument horizontally. In this way it serves as an ordinary pocket compass. Messrs. W. & L. E. Gurley, of Troy, New York, make several different forms of this instrument. That with a 3-inch needle has the two sides of glass, and is provided, when desired, with a stop for the needle. Another form has a brass back and cover, and a $2\frac{1}{2}$ -inch needle. Another represents an improved compass by the same makers. It is a modification of Swedish compass, and has a needle 3 or 4 inches long, resting upon a vertical pivot so as to move freely in a horizontal plane, and thus place itself in the magnetic meridian; while being attached to the needle-cap by two delicate pivots, one on each side, it is free to dip. It is usually provided with brass covers on both sides.

With the dip compass, whether Swedish or American, perfectly trustworthy results can only be obtained when the observer is acquainted by long experience with the peculiarities of his instrument. Compass explorations being in many cases the sole source of income, it can easily be understood that a skilful operator will be inclined to keep his mode of procedure secret. Consequently the uninitiated are apt to believe that the operator must be specially gifted; and frequently the supernatural properties formerly ascribed to the divining rod are transferred to the compass. This excess of faith in some is accompanied by scepticism in others. For this, unfortunately, there are good grounds; the compass being so admirably adapted for dishonest purposes. Thus, Mr. T. B. Brooks mentions an American prospector whose compass needle in the vicinity of an ore mass always showed a dip of 90° when facing west, and the true dip due to local attraction when facing east. The former position, it is said, was very successfully used in selling iron ore grounds, and the latter in buying them. Similarly in Sweden a powerful magnet inserted in a walking-stick has been successfully employed to give a large dip to the needle when it was thought desirable to mislead the purchaser.

As a rule, surveyors assume that the most ore must occur where the tip compass shows the greatest inclination, or is perpendicular. This assumption, however, is erroneous. The place where the needle is attracted most by a vertical ore bed is not directly above, but to the north of, the south pole of the deposit. For, if the magnetism of the earth is powerful enough, there must be somewhere north of the ore pole a point at which the horizontal components of the magnetism of the earth and of the ore bed are equally powerful, but acting in opposite directions. At this point the horizontal forces neutralise each other, and then the

vertical forces of the magnetism of the earth and of the ore bed tend to bring the needle into a vertical position.

The evidences afforded by the needle often lead to error. An unimportant pocket of ore near the surface may have as great an action on the instrument as a larger ore mass situated far below the surface.

It is thus seen that in exploring for iron ore, with the magnetic needle, a purely scientific method is necessary. The compass should be employed for preliminary work, in order to save time and labour; but before a shaft is sunk, recourse should be had to a more accurate method. Improved methods, available for the purpose, have been devised by Brooks, Wrede, Thalén, and Tiberg.

BROOKS' METHOD.

Mr. T. B. Brooks, of the Geological Survey of Michigan, in exploring for iron ore, determined with a pocket compass variations east or west; the bearings of a standard line being taken as in ordinary surveys. The inclinations or dips were observed on the dip compass held in the hand in the plane of the meridian. Sometimes observations were made with the compass held at right angles to this position, that is, facing north and south. The instrument was always held in the hand and levelled by its own weight. The intensity of the magnetic force for the three positions of the compass was measured by the number of oscillations made by the needle in a unit of time, usually taken at a quarter of a minute. No attempt was made to eliminate the earth's attraction by neutralising it with a magnet while the observation was being made, nor by computation; and the great amount of friction in the compass renders the number of oscillations only an approximation to the number that would be obtained with a delicately mounted needle. Mr. Brooks has, however, done excellent work with this method in the Marquette region and in New York and New Jersey. He also describes another method of working, which he calls magnetic triangulation. The mode of procedure is as follows:—Remote from any magnetic rocks, neutralise, by means of a bar magnet, the earth's influence on the needle of a solar compass. The needle will then stand indifferently in all directions. If the compensated instrument is set up near the magnetic pole to be determined, the needle will point as nearly towards the local pole as its mode of mounting will permit. The operation being repeated at two other points near the magnetic pole, the three lines must intersect in one point, which will be directly over the pole of which the position is sought. By using a dip compass in a similar manner, data to determine the depth would be obtained. The fact that several local poles often influence the needle at each station renders this method difficult in practice; a place must be sought where but one strong pole exists.

To be continued.

Electricity in Coal Mining.

A number of gentlemen interested in electric lighting met lately in London to witness the capabilities of the "Eclipse" portable electric battery, which, with its low-resistance lamp, has already been tested with gratifying results on the Great Western Railway and elsewhere. The lamp is suitable for domestic illumination, and is said to be the safest and most economical electric light in existence. It is also adapted for railway signals, private carriages, omnibuses, &c. It is conspicuous as a miner's safety lamp, and only weighs 4 lb. or 5 lb. The battery is

charged with the simplest ingredients, viz.: sulphuric acid and common soda, and while the battery and lamp may be obtained for a few shillings, the cost of the charge is only 2d., and it will last for 24 hours. Dr. Silvanus P. Thompson, speaking of the qualities of the "Eclipse" electric battery, and of the miner's lamp in particular, said that a short time ago he, with many other gentlemen, was engaged on the Woolwich Commission in the inspection of 200 different miner's lamps, and that when the test of blowing them up was tried, not a single one would stand the test. He added that there are 100,000 miners injured every year, not only by explosions, but many other causes which arise entirely from deficient light. In the "Eclipse" miner's lamp the light was thrown upwards as well as sideways, and, even if it were true, which it is not, that it cost ten times as much as the ordinary safety lamp, he thought it ought to run the ordinary safety lamp out of existence. He could verify the statement that the batteries would run at least 13 hours. That in itself was quite sufficient to show the advantage of this over the ordinary miner's lamp. Dr. Thompson stated it was quite impossible to blow the lamp up, and that it could not possibly cause an explosion.

PHOSPHATE

The following shipments of Canadian ore have been made from Montreal for month ending 30th June 1887:—

LATEST ENGLISH QUOTATIONS.—MINERAL PHOSPHATES.—There is a fair enquiry for High Class Canadian, but very little offers at present. It is, however, expected that now the fine weather has set in, Raisers will soon be in a position to estimate their production, and the quantity they may have to sell over the Summer season. The price for South Carolina Phosphates has advanced with the rise in Steam Freights, and 7½ to 7½ per unit is now the quotation for River and Land, according to the quantity required. Belgian Phosphate—little has been doing during the month,

Raisers of 40/45 per cent. declining to sell more at late prices, and with two more Works lately producing the material closed, it is much scarcer. The higher grades are offering freely, and we could contract for next season on favourable terms. Somme Phosphate of all (except 75/80 which is firmly held by the two Raisers producing it) is offering at lower prices; several of the smaller Manufacturers are getting into difficulties with the Iron and Alumina guarantee.

Owners of phosphate properties have been much encouraged by latest advices, which announce sales at 1s. per unit, which is equal to £4 per ton.

The Templeton & Blanche River Phosphate Mining Company commenced operations on their property early last month, and so far the management are well pleased with their prospects. The deposits owned by the company are located on lot 7, on 11th Concession, half of lot 6, on 8th Concession, and lot 5, on 9th Concession, Township of Templeton. The work, which at the outset was somewhat scattered, is now being concentrated at two special points and will now be conducted vigorously.

At the Otty Lake Mines five pits are now being worked, and others will shortly be opened. One of the pits has been producing a high grade red phosphate until lately, when a change took place in the character of the vein, and now the product of the pit is composed of a beautiful green phosphate of a very high grade. The pit is about 45 feet deep and is worked by one of the steam cranes used some years ago by the Montreal Steam Crane Co. in unloading ships on the wharves at Montreal. Another pit, opened about two weeks ago, is on a vein of phosphate and calcite. The phosphate occurs in seams and pockets in the calcite; and near the surface cavities are found containing on their floors large quantities of fragments of crystals which require only to be shovelled out.

Mr. F. Van Bruyssel, the Consul-General for Belgium, has paid us a visit with the object of obtaining as full information as possible regarding our phosphate deposits. Samples of the ore taken from the leading Canadian mines were given him, and these, we have since learned, have been forwarded to His Excellency Prince de Chemay, Minister of Foreign Affairs, Brussels. The quantity of fertilizers used in Belgium is much greater than we had any conception of.

At the High Rock Mines about 600 tons of high grade ore have been raised during the past month. The management hope to ship over 8,000 tons during the season. Mr. Pickford, Sr., has been at the mines for over a month and states that the pits are looking very well and that everything goes smoothly. A "chute" has been constructed from the end of the tram line over the river bank, which will greatly facilitate the loading of the ore.

Mr. McIntosh has resigned his position at the Union Mines. He will shortly open up his property near High Falls.

The shaft at the North Star Mine has reached a depth of 600 feet, and is still showing a fine vein of ore all the way down. The management are very busy moving their output to the river, which is some four miles from the mines.

About 400 tons of ore per month is being shipped to Montreal from the Union mines. Capt. J. E. Smith has entire charge of the mine.

The tram line at Little Rapids is proving a most successful acquisition, and the ore at this valuable property is now being handled with great facility. Five men can by this means load a scow with 70 tons of ore from the mines in seven hours. As the majority of the hands have been employed on the work of constructing the tramway, the output during the month is somewhat below the average.

Mr. Boyd Smith, of Washington, D.C., who is engaged phosphate mining at Charbot Lake, Mr. Pickford, Sr., and others interested in phosphate mining, paid a visit to this property on 11th inst. They were particularly impressed with the mode of cleaning the ore and expressed themselves much pleased with the working of the property.

At the Emerald Mine a very steady output of high grade ore continues, and the prospects for the season are bright. About 500 tons are being shipped per month.

Work on the new Locks near Little Rapids has at last been commenced. The improvements are badly wanted and it is to be hoped there will be no further delay in the work of immediate construction.

The Canadian Pacific Railway are doing everything in their power to meet the requirements of the miners in the transportation of their ore. Managers report themselves as much pleased at the improved facilities given them by the road since last year.

MINING NOTES.

Nova Scotia.

New Glasgow, says an exchange, is growing to be a busy place. Within a circle of two or three miles there are half a dozen collieries employing 1,700 or 1,800 men, while the glass works, steel forges, foundries, plough works, carriage factories and other smaller industries furnish profitable employment for 1,000 hands. The Short Line Railway gives it closer connection with the West, and if all the expectations of the enterprising men who have built high hopes on the future of New Glasgow are realised it will become the Newcastle of Canada. When Nova Scotia decides to replace its wooden ships by iron and steel, New Glasgow and vicinity is the locality where it will be done, as the material is there and only requires the necessary energy and capital.

Gold mining, says the *Critic*, is being vigorously pushed in all the gold districts in the Province, and with most encouraging results. In Yarmouth County, the Kempt Gold Mining Company are pushing operations on a more scientific scale than before, and from all accounts the Company are likely to be richly rewarded for their determination. The Cowan Mining Company has a splendidly equipped mine and it is reported that the property is about to be sold at a good high figure. Prospecting is being vigorously pushed, and new finds are likely to be reported at any moment.

The official returns for the month of June are as follows:—

District.	Mill.	Tons Crushed.	Oz. Gold.
Tangier.....	Mooseland.....	21½	15½
Sherbrooke...	Miners'.....	25	8½
".....	Goldenville.....	52	8
East Rawdon...	Rawdon.....	350	342
Lake Catcha...	Oxford.....	93½	138½
Brookfield...	Brookfield.....	200	122½
Whiteburn...	Cnsling C. M. Co..	20	53½

New Brunswick.

The manganese property, at White's Mountain, is reported to be showing up well. It is thought that probably \$2,000 worth of ore is on the dumps.

It is understood that efforts are being made to form a joint stock company with a view to operating the manganese property at Petitcodiac.

Quebec.

Our correspondents from the Asbestos districts write:—"We have nothing special to report in Asbestos. Operations have been prosecuted steadily since our last with the exception of some interruption last week from local heavy rains. Men are getting scarce just now, many being employed haying, which has been commenced by the farmers. Prices on Crude Asbestos remain the same and there is a somewhat larger demand this year."

The Oxford Copper and Sulphur Company, of Capelton, Que., Bayonne, N. J., and New York, have suspended payment, but are maturing plans by which they expect to resume business and pay up their liabilities of \$600,000 in full. The company owns valuable copper mining property in Canada and the earnings during the last year showed a fair profit, which was devoted to improving the plant and developing the mines. The company have a large stock of copper on hand at their smelting works at Bayonne, as well as valuable mining lots at Capelton, so that the failure is not expected to turn out a bad one, and a fair dividend may be confidently looked for.

Ontario.

The properties owned by Messrs. Jenkins & Chambers in 18th, 2nd, 8th and 15th concessions of Wollaston give promise of being the most extensive iron deposits yet discovered in Ontario. The Station mine shows a continuous length of over 1,500 feet with a width varying from 20 to 100 feet. A Government analysis of ores from the 2nd concession shows 56 per cent. metallic iron with no injurious elements. The deposits in the 2nd and 15th concessions are still larger than that mentioned. It is to be regretted that lack of capital prevents the full development of these very promising deposits.

The *Journal of Commerce* of 8th inst. announces that:—

"A syndicate composed of Milwaukee and Chicago capitalists, of whom Hnstis, Coughlan and Ray are the representatives, recently purchased a tract of 200 acres of mineral land in the Township of South Crosby, Leeds County, Ontario. They have been doing some prospecting, and some samples of ore were received in Chicago this week, and the company at once received an order for 1,000 tons at \$6 per ton from a Chicago steel company."

There is nothing to report from the Bristol Iron Mines. We hope to give our readers some idea of the progress being made there in our next issue.

A discovery of exceedingly rich native silver has been made on Pitch River, on a location owned by the Ottawa Mining Company.

Another vein of gold is reported to have been found on the property owned by Mr. Coffee, near Sudbury.

PORT ARTHUR DISTRICT.

The mines in the vicinity of Thunder Bay are deservedly attracting considerable attention at the present time, for every day brings fresh evidence of the unquestionable richness of that vast mineral region. Latest advices report a very rich discovery of silver, which has been made at Atick Lake, about fifteen miles west of Silver Mountain and within two miles of the present terminus of the located lines of the Port Arthur, Duluth and Western Railway. The fortunate possessor of what is an undoubtedly very valuable property is Mr. W. A. Allan, of Ottawa, who is bound to realise handsomely on his investment. He will develop the property forthwith. We understand that Mr. Allan's agents are still prospecting in the Whitefish Region. Their reports indicate that further discoveries will very shortly be made public.

Another new find has been made about ten miles west of Silver Mountain and about half a mile north of the railway route and immediately east of the property now being worked by the Queen Mining Company of St. Paul and across whose property, as well as the adjacent one in the east, owned by Mr. Dounais, the vein runs. This has been secured by one of our enterprising merchants who was pointed out the vein by a brother of the celebrated Louison, the discoverer of the Rabbit and Silver Mountain mines.

Messrs. Eschweiler & Buchanan are getting out rich ore from their property near the Porcupine mine.

The Ontario Silver Mining Company has been organised at St. Paul, where the principal office will be, with a capital stock of \$2,000,000, shares \$5 each, to work property located at Location R 146 and R 147 in Thunder Bay District. The officers are: Edward H. C. Taylor, President; Robert M. Fulton, Vice-President; Albert K. Murray, Secretary; Thomas Tyrer, Treasurer.

Manitoba and North-West Territories.

As already announced the Galt Coal Mines at Lethbridge have been temporarily closed down owing, it is claimed, to the arbitrary action of the miners. An association was formed by the miners some time ago, and owing to the distance of the mines from any centres of population, and the difficulty of obtaining men, the employees have had things practically their own way. Their action at last became so unbearable that the Company decided to close the mines, until new men could be procured from the East. A sufficient supply of coal is on hand to fill requirements until work can again be started. The *Athabasca*, which arrived at Port Arthur on the 5th, brought up seventy miners from Columbus, Ohio, who are going to work in these mines.

Shipments of coal from the mines of the Canadian Anthracite Company, at Banff, are being vigorously conducted. Winnipeg and San Francisco are the points so far to receive the largest consignments.

British Columbia.

A dispatch from Sand Point, Idaho, says: "The first shipment of silver ore into the United States from British Columbia was made on 15th June, from Kootenai, a flag station four miles east of this point on the Northern Pacific Railroad. The ore goes to Montana for reduction, and runs about 400 ounces of silver per ton. It was shipped from the Krao mine, on Kootenai Lake, British Columbia, by one of the owners, A. D. W. Wheeler."

The 80 stamp quartz mill for the Alaska Union Mining Company, on Douglas Island, has arrived from San Francisco.

A valuable discovery of platinum is reported at Granite Creek.

Letters from Big Slide state that the river is receding and that the works at the Foster mines had not been damaged, only the lower floor of the chlorination works having been under water for three or four days. The difficulty in chlorinating the concentrates had been partly overcome, a tub having been "gassed" in nine and a half hours. The tailings show a heavy loss in gold, and steps have been taken to ascertain the reason of the loss and check it.

The *Colonist* states that an immense deposit of finest lime has been located on McDonald's farm, near Agassiz station. A company has been formed for the purpose of bringing it into market, and kilns are now being built for that purpose. It is most conveniently situated, for it can be loaded on steamer or scow direct from the kilns, and a tramway can readily be built to the railway line.

Copper has been found in the Blind River district. The find is reported valuable.

Mineralogy, Geology & Science.

The Correlation of the Animikie and Huronian Rocks of Lake Superior.

By Peter McKellar, Esq., Fort William.

In his excellent paper upon this subject read before the recent annual meeting of the Royal Society of Canada, Mr. McKellar, who has had over twenty years practical experience among the rocks of both sides of Lake Superior, gave convincing evidence of the true relations of all the rock formations of these regions. In his opening remarks he referred to the diversity of opinion that of late years has existed among American geologists who have combatted the stratigraphy of the rocks of the North Shore, as defined by Logan and other Canadian geologists alleging that the lower group of the upper-bearing series of Logan (now called Animikie) is identical with the Huronian. Mr. McKellar shows the general dissimilarity of the two formations and then proceeds to give an analysis: First, of the lithological features and secondly of the stratigraphical arrangement of each, by which their strong contrast is brought out. His intimate knowledge of every part of the ground covered makes it impossible

to controvert his facts, and his reasoning is conclusive and entirely favourable to the position taken by our geologists. The Huronian rocks of the different areas north of the great lakes differ more or less from one another, both as to the presence or absence of some of their lithological constituents, and in relative volumes or proportions of certain kinds of rocks which may be present: but in the main Mr. McKellar thinks that the general lithological difference between these areas may be considered as of degree and not of kind. "No good reason," he said, "has yet been shewn for considering any of them as entitled to a separate classification. To attempt to do so, in the present state of our knowledge, would only lead to confusion. The so-called 'Typical Huronian of Lake Huron,' contains the same kinds of rocks as the 'Huronian areas' of Lake Superior, although the quartzites are in relatively larger volumes, and possibly part of the former series may prove to be a little newer than most of the latter. If the Lake Huron quartzites and their associated rocks could be shewn to belong to a formation distinct from all the rest of the rocks which have been classified as Huronian, it might then become difficult to prove their chronological relation to the Animikie formation. Stratigraphy would give but little aid in ascertaining their relative positions, if their equivalency with the Huronian schists of Lake Superior were in doubt. But I believe that almost all geologists are agreed, Prof. Irving among the number, that they belong to the same system. The somewhat lower angles of dip than the average in part of the Lake Huron region, and the relatively large development of the quartzites are the circumstances which have caused doubts in the minds of some who have lent limited personal knowledge of the Huronian system as to their equivalency with the rocks of the age on Lake Superior, which are generally more schistose. But many other examples could be given of low dips in various Huronian regions. Again the quartzites of Lake Huron are conformatibly associated with great volumes of crystalline Schists, apparently identical with those of Lake Superior. The white and gray quartzites of different shades are met with in the Huronian bands north of Michipicottau, at Red Lake (to the north Lake of the Woods) and elsewhere. Dr. Bell has shewn that they exist in *great force* among rocks of the ordinary Huronian types on the North-West Coast of the Hudson's Bay. My personal knowledge of the rocks of Lake Huron is not so complete as that of Lake Superior, but from the descriptions of Sir William Logan and others and what I have myself seen on the Lake Huron Strata, the greenstones and schists of the formation there appeared to me to be precisely the same in character as these equivalents on Lake Superior, and they are not in the least like the rocks of the Animikie formations. Even the veinstones of the former region are markedly of the Lake Superior Huronian type and quite different from those of the Animikie series. My impression is that the original Huronian of Lake Huron can never be shewn to be equivalent to the Animikie, any more than the Huronian of Lake Superior. They must either be classified with the last mentioned or as an intermediate formation." Incidentally connected with this question is the relation of the Animikie group to the Keeweenawian, and on this subject Mr. McKellar stated the results of his own observations. These questions are of great economic importance in connection with the occurrence of native copper in the Keeweenawian, of silver in the Animikie, and of iron in the Huronian series.

FOR SALE. VALUABLE. Copper Mining Properties — IN THE — Eastern Townships

TOWNSHIP OF ASCOT.

- 1st. Clark Mine, Lot 11, R. 7 Ascot 187 acres
2nd. Sherbrooke Mine, part Lots 12 and 13,
R. 7 Township of Ascot..... 329 "
3rd. Belvidere Mine, part Lots 9 and 10, R.
9 and 10, R. 8 Ascot 292 "
4th. Mining Rights in same vicinity on..... 250 "

All of the above properties lie within $1\frac{1}{2}$ miles of the Village of Lennoxville, at the junction of the Grand Trunk, Canadian Pacific and Passumpsic Railways, and have been developed to a considerable extent, and veins opened 6 to 20 feet in width, yielding 3 to 5 per cent. of copper, also silver, and 35 to 40 per cent. of sulphur. These mines are only $2\frac{1}{2}$ to 3 miles distant from the City of Sherbrooke, and evidently are of the same class of ores found at Copelton, only four miles distant, owned and worked by the Orford Copper and Sulphur Company, and by Messrs. G. H. Nichols & Co., of New York, which have proved so remunerative.

TOWNSHIP OF ORFORD.

- 5th. Carbuncle Hill Mine, Lots 2 and 3 R. 14, and 2, 3, 4 R. 15, 718 acres. Same class of ore as is found in the Ascot properties above described, but yielding a higher percentage of copper.

TOWNSHIP OF CLEVELAND.

- 6th. St. Francis Mine, $\frac{1}{4}$ Lot 25 R. 12, 50 acres, with dwelling houses, smith's shop, ore sheds and office, large winding and pumping steam engine, with boiler, winding and pumping gear, and about forty fathoms Cornish lifting pumps complete, railway tracks, ladders, etc., situated three miles from Grand Trunk Railway. A considerable amount of mining work has been done at this mine. A well defined vein richly charged with vitreous purple and yellow sulphurets of copper traverse the entire length of the property, five feet in thickness, yielding 8 to 40 per cent. metallic copper.

TOWNSHIP OF GARTHBY.

- 7th. Fifty-six lots of land, 2,938 acres. This property for the most part is unexplored, but copper is found on the greater part of the property. On one of the lots a vein about twenty feet in width has been found. Samples of the ore have yielded as much as 22 per cent. of copper, being also rich in sulphur. Other samples of pyrites from the same property, free from copper, have yielded as high as 48 per cent. of sulphur. The only drawback to this property is in its distance from the railway, it being about four miles from Garthby Station, Quebec Central Railway. A new line is chartered, however, which, when built, will run directly through the property.

TOWNSHIP OF ACTON.

- 8th. The Acton Mine, 100 acres, with engine, boiler, pumps and appliances. Within three years after this mine was first opened it produced nearly \$500,000 worth of copper. It is situated about half a mile distant from the stations of the Grand Trunk and South Eastern Railways.

- 9th. Brome Mine, part Lots 2 and 3 R. 4, 50 acres.
10th. Bolton Mine, two miles from Eastman Station, Waterloo & Magog Railway, 400 acres.

The above properties formerly belonged to the Canadian Copper and Sulphur Company, and were acquired by the present owner at sheriff's sale, giving an indisputable title thereto.

The whole or any portion of the property will be sold at reasonable prices.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should any person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:—"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR

T. STEWART.

ALEX. FLECK, JR.

CHEAP AND THOROUGHLY GOOD SAW-IRONS

Suitable for Small Water Power,
Light Threshing Engines

Capacity with 12 h. p. 3000 to 4000 feet per day.

Has Patent Peel Dogs, Lumber Gauge, Saw Guide,
Steel V Truck, Reservoir Brass Boxes.

Given up A 1 in all
respects.

AUTOMATIC SHINGLE MILLS. CHOPPING MILLS.
LATH MILLS. DOUBLE EDGERS.
SAWS, SAW TOOLS, and EWEART CHAIN for conveying,
and elevating.

Waterous Engine Works Co.,

Brantford, Canada.

St. Paul, Minn., U. S. A.

STYLE 26 B, - PRICE \$115.00.

ORCHESTRONES.

STYLE 26 B,	-	-	-	\$115.00
" 44 B,	-	-	-	115.00

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Barn and Stabling at Experimental Farm, near Ottawa," will be received at this office until THURSDAY, 4th August, for the several works required in the erection and completion of the

Barn and Stabling at Experimental Farm, near Ottawa.

Plans and specifications can be seen at the Department of Public Works, Ottawa, on and after Saturday, the 23rd July.

Intending contractors should personally visit the site and make themselves fully cognizant of the work to be done, according to the said plans and specifications, before putting in their tenders.

Persons tendering are further notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted bank cheque made payable to the order of the Honorable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender is not accepted the cheque will be returned.

The Department will not be bound to accept the lowest or any tender.

By order,

A. GOBEIL,
Secretary.

Department of Public Works,
Ottawa, 15th July, 1887.

6-1

NOTICE RESPECTING PASSPORTS.

PERSONS requiring passports from the Canadian Government should make application to this Department for the same, such application to be accompanied by the sum of four dollars, in payment of the official fee upon passports as fixed by the Governor-in-Council.

G. POWELL,
Under Secretary of State.
OTTAWA, 19th Feb., 1886.

Department of Inland Revenue.—An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue and the provisions of the foregoing sub-section have been complied with.

Every person who sells or offers or exposes for sale any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always that deficiency of one per centum of the ammonia, or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and entitled, "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Four Detached Residences at Experimental Farm, near Ottawa," will be received at this office until MONDAY, 29th August, for the several works required in the erection and completion of the

Four Detached Residences at Experimental Farm, near Ottawa.

Plans and specifications can be seen at the Department of Public Works, Ottawa, on and after Monday, 15th August.

Intending contractors should personally visit the site and make themselves fully cognizant of the work to be done, according to the said plans and specifications, before putting in their tenders.

Persons tendering are further notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted bank cheque made payable to the order of the Honorable the Minister of Public Works, equal to five per cent. of the amount of the tender, which will be forfeited if the party declines to enter into a contract when called upon to do so, or if he fails to complete the work contracted for. If the tender is not accepted the cheque will be returned.

The Department will not be bound to accept the lowest or any tender.

By order, A. GOBEIL,
Secretary.

The Phosphate Trade of Canada.

By H. B. Small, Ottawa.

There are probably very few persons beyond those interested in the trade who know what Apatite is, or to what uses it is applied, and when they are told that the shipments of crude rock in 1886 reached the large amount of 24,876 tons, and that they are annually increasing, they will naturally seek some information respecting it. Apatite is the crystalline form of phosphate of lime, used largely for the manufacture of superphosphates when treated with sulphuric acid. It is only within the last few years that attention has been given to its existence in Canada, although the late Sir William Logan cites its existence in certain localities. Specimens of it, and very pretty they look in a cabinet, might have been seen in museums or in private collections, but the great wealth it would bring to the country was little thought of, and mining it on any large scale would, till quite recently, have been looked upon as a waste of money. To day, however, it is taking its place as one of the foremost industries in Canadian mining, and with the exercise of care and judgment apatite mining affords a handsome return to those who engage in it. This industry, moreover, adds to the general wealth of the country, by the circulation of money in the purchase of agricultural products to feed the miners, for boats and railways transporting it to the seaboard for shipment, to the vessels which carry it across the Atlantic, and to the brokers and commission merchants who handle it before it reaches its British purchasers.

Prof. Boyd Dawkins, an eminent geologist, who, when in America with the British Association, visited the Ottawa County mines, stated, in a paper read by him at Manchester, on his return, that in his opinion phosphate was "one of the most important resources of Canada."

When Liebig, in the year 1840, compelled the agricultural community to accept his views of exhaustion and restoration of the soil, and that the constant removal therefrom in the harvest of the inorganic elements of plant food, notwithstanding the rotation of crops and the old system of manuring, was a robbery of the soil, which enriched the present at the expense of the future, he may be said to have been the founder of an industry which has assumed constantly increasing proportions ever since. That industry is the manufacture of fertilizers or superphosphates, and the demand for materials from which these can be manufactured led to a search for and consequent working of natural deposits in which phosphate of lime preponderated. It is not our intention to

go into the question of fertilizers further than to state *en passant* that in supplying the nutritive elements of plants in the form most favourable for absorption and assimilation, the whole art of manuring consists, and that as ordinary manure does not always contain the two most important inorganic elements of plant food, phosphoric acid and potash sufficient for plant use, the needs of mankind demand the employment of artificial fertilizers along with or as a substitute for farm-yard manure.

Dr. Dawson, the assistant director of the Geological Survey of Canada, in a paper read by him before the Ottawa Field Naturalists' Club, in 1884, reviewed very concisely how phosphorous was essential to all living tissues whether vegetable or animal, and in following the transmission of that substance from the soil to the plant, from the plant to the animal, and from the animal again to the soil, he further pointed out that this cycle of nature is interfered with and broken by the massing of population in large towns where the phosphates and other substances valuable to agriculture are lost. He also cited statistics of the amount of phosphorous actually contained in the grain annually shipped from the port of Montreal, estimating it for this purpose in the form of phosphoric acid. Wheat contains eight-tenths per cent. of this, or about sixteen pounds to the ton, and a very little calculation will show annually the enormous amount carried away, and a still further calculation, based on the average quantity (about two-tenths per cent.) contained in ordinary soils, gives the amount of phosphate of lime required to restore and maintain the fertility of the fields. With these statistics the necessity is evident of having sources of supply of phosphates, the most available of which are concentrated natural deposits. The questions that follow are: what is the nature of them? Where do they occur? How have they been formed?

To the first of these questions let us take Dr. Dawson's own words: "The concentration of phosphates in nature is generally found to have been brought about by organic agency," and he then cites as the first example guanoses, composed essentially of the excrements of seabirds. These are divided into two classes, nitrogenous and phosphatic. In the former, which belong exceptionally to dry climates, the organic matter converted by decomposition into ammonia salts, remains as part of the mass, but in the latter the rain has removed the soluble ammonia, leaving the phosphatic matter. This is the case with the West Indian guano, and the coral rock, penetrated with hollows and fissures has become so permeated with phosphatic accumulations that it is known as phosphate rock. The deposits in the South of France, known as Bordeaux phosphates, are looked upon as of a similar origin, the higher parts, the plateaus of Jurassic limestone in which it is found appearing to have formed at one time an archipelago in a tertiary sea, like the West Indian Islands of our own time. This phosphate rock, however, is of very modern origin geologically

speaking. Coprolite beds, such as the phosphate rock of South Carolina, have their origin in a different source, and are traceable to the accumulations in shallow tidal estuaries of ancient seas, of molluscs, bones and other marine organisms massed together by concretionary action, and forming layers similar to the well-known mussel beds on many parts of our sea coasts to-day. But the expression coprolite, applied as it is to Carolina phosphate, is erroneous. It should only be applied to the fossil excrements of various animals, notably the saurian monsters of the antediluvian shores, and which are so abundant in the eastern counties of England that coprolite pits have been worked there for many years. Crystalline phosphate or apatite is new, different in appearance from the preceding, and Dr. Dawson remarks, speaking of it, that in the Laurentian rocks of Canada are sediments deposited in the earliest seas of which we have any trace, but which originally resembling those of later seas, have been so completely altered that their materials have entered into new combinations, and have by igneous action become entirely crystalline, resembling now the original deposits as little as do the crude ingredients of glass the finished product. In substantiation of this theory limestones thus acted on would assume the crystalline character of marble, beds of a peaty or coaly nature would pass into graphite or plumbago (crystalline carbon), and phosphatic layers would appear as crystalline calcic phosphate or apatite. All these substances are found in contiguous zones or belts in the Laurentian rocks near Ottawa, an evidence pointing directly to the correctness of this theory. The greatly disturbed character of these rocks explains the irregularity of their deposits, as layers which, before the great folding and kneading together caused by igneous and volcanic disturbance may have possessed regularity and uniformity have been so dislocated and upset as to lead to the production of large pockets and irregular masses connected only by narrow and twisted seams, so narrow sometimes as to appear as isolated portions.

The principle sources of supply may be stated as follows:—the West Indies and other islands of the Caribbean Sea, supplying what is known to the trade as Sombrero phosphate, or rock guano as it is sometimes called, of high quality; Navassa, from its impurities can only be used for a lower grade of superphosphate; Maracaibo or Mark's Island, is of very high quality; St. Martin's Island, of good quality; Aruba Island yields a variable quality, and Pedro Keys and other small islands yield an uncertain supply. In the Pacific Ocean, Baker, Jarvis, Howland, Malden and Starbuck islands afford a high class rock guano. In the South of France the Ardennes region affords what is known as Bordeaux phosphate, so called from the port from whence it is chiefly shipped. The valley of Lahn, in Nassau, yields what is known as German phosphate. The eastern counties of

England, Cambridgeshire, Bedfordshire and Suffolk produce coprolite of high quality. Boulogne, in France, yields coprolite, used largely for mixing with materials of a higher grade. South Carolina, in the United States, produces large quantities of phosphate known as Charleston rock, of a low grade, but very largely used, its composition being easily attacked by acid.

Crystalline phosphate of lime or apatite, the purest form which is at the manufacturer's disposal, is now becoming more and more sought after owing to its high percentage and greater purity, and Canada will, from present appearances, be the chief source of supply. Norway furnishes an excellent quality of this material, but the supply is limited. Spain produces large quantities of apatite, and in Extremadura and the neighbouring districts of Portugal large deposits have been known to exist for some years, but have only recently been worked to any extent. The above mentioned places are the only known sources whence apatite is obtainable, and as a consequence the great value it assumes from its limited sources of supply must be at once apparent.

In his report on the County of Hastings, in the Province of Ontario, in 1871, Mr. Vennor, late of the Geological Survey staff, called attention to large deposits of apatite existing there that had been quarried on and off for over 20 years. The richest of these occur in the township of North Burgess, where a number of "openings" were worked with fair returns. These deposits he named respectively "the North Burgess Basin," and "Bedford, Storrington and Longboro Basin." Analysis of specimens taken from these in different localities gave as an average 88 per cent. of phosphate of lime. The mineral has now been discovered more or less all through the district lying north of Kingston and Belleville, and although mining is now carried on there on scientific principles, it is as yet in its infancy as far as that part of the country is concerned.

The Laurentian Mountains of the Province of Quebec seem to offer greater advantages than elsewhere for this species of mining, especially in the district lying northeast of Ottawa and within a radius of 30 miles from the capital. This Laurentian range meets the eye when ascending the river St. Lawrence from the sea and runs parallel to it on the north shore, and diverging somewhat east of the confluence of the Ottawa River, follows the course of the latter westward by north sending a spur across it near Portage du Fort, which penetrates the Kingston district alluded to before. The natural formation of these mountains is far from being conducive to agriculture, the country presenting a succession of small isolated, rounded, rocky hills, alternating with numerous lake basins. The rocks, though concealed in the valleys by considerable depths of alluvial soil, are seen in the hills to be hard and undecayed. After the first growth, which covers these hills in a state of nature, has been cut, the undergrowth is apt to be destroyed by fire and the comparatively thin layer of soil is laid bare, which being soon washed away by the rains, exposes the rock and renders the region

sterile. With the exception of straggling settlers here and there in the valleys all this district had been left as valueless till the discovery of the presence of apatite brought it into notice, and land, which was held by the Crown at 30 cents an acre, was bought up by speculators and realized fabulous prices for mining purposes. The latter is carried on principally in the townships of Buckingham, Templeton, Wakefield, Hull, Derry, Portland and Bowman, the two former being the chief fields of present operations. Exploration shows that apatite is to be found in a much wider district than the above mentioned, the zone containing it running in a north-easterly direction from the Blanche River across the River Lievre into the adjoining country east, and then taking a curve backwards in a north-westerly course. The belt is very productive and yields a very fine quality of apatite.

(To be continued.)

Use of the Magnetic Needle in Exploring for Iron Ore.

By Mr. B. H. Brough, Assoc. R.S.M., G.G.S., F.L.C.

(Continued from July number.)

WREDE'S METHOD.

The method proposed by the Baron F. Wrede, in 1874, consists in exploring for two points, one east and the other west of the ore mass, at which the deflections of the needle from the magnetic meridian are equal, but to the west on one side and to the east on the other. The observations are made in the ore field in the direction of the magnetic east and west line, the approximate position of which is assumed to be known. Midway between the two points there must be a third, where there is no declination. The position of the meridian passing over the ore body is thus determined. It is then necessary to determine the magnetic intensity and inclination, in order to calculate where the ore pole is situated. For this purpose it is necessary to find out the position of that point for which the horizontal component of the earth's magnetism is zero, and where the angle of inclination due to the magnetism of the ore bed alone is 90°.

THALÉN'S METHOD.

Professor R. Thalén, of the University of Upsala, employs a modification of Weber's portable magnetometer, or of Lamont's theodolite. He cannot be said to have invented the instrument, since its principle has been known since Gauss' time (1830). Weber's magnetometer dates from 1836, and Lamont's theodolite from 1840. In its simplest form, the instrument consists of a compass box $3\frac{1}{2}$ inches in diameter, divided into degrees or half degrees. At right angles to the diameter, passing through the zero point of the graduation, an arm extends horizontally. This serves as a sight in setting out lines in the field, and receives the bar magnet for the deviation measurements. A deflection of the needle is caused by means of this magnet, the longitudinal direction of which is parallel to the arm, and the distance of which from the needle always remains unaltered. On the other side of the compass box there is a socket, into which a rod of soft iron can be placed perpendicularly for inclination measurements. This iron rod, like the magnet, affects a deflection of the needle. The instrument rotates about a vertical axis, and is provided with a spirit-level and levelling screws. In order to simplify the apparatus still further, the compass box may be fastened to a rectangular board, the edges of which can be used as sights; whilst the board

itself receives the bar magnet, which is fixed by screws or springs into the position that is determined once for all. As support for the instrument, an ordinary surveyor's plane-table may be employed.

The observations with the magnetometer consist for the most part of deviation measurements, for which two different methods may be employed. In one method the instrument is placed so that the needle is directed to the zero point, the bar magnet having been removed from its place. Directly the magnet is replaced the needle will deviate from its original position, the angle of deviation being read from the graduated circle. In the second method the instrument is turned, while the magnet is in its place, until the needle points to zero. The bar magnet is then removed, and, when the needle has come to rest, the angle is read. In this method, under similar conditions, the angle obtained will be greater than in the former method. Of the two methods, the latter, or *sine method*, is the more delicate; but it requires more time than the former, as the instrument has to be re-adjusted at every observation with the magnet and iron rod. This method has the disadvantage of not being applicable in the extreme north of the ore-field, where the magnetism of the ore-bed is powerful. In the former, or *tangent method*, the instrument remains unmoved during both measurements. The disadvantage, however, is that the so-called constants of the instrument vary with the angle of deviation. This does not matter if the results are to be arrived at geometrically, since it is then merely necessary to join the points where the same angle is obtained, quite regardless of the magnitude of the angle and of its corresponding constant. If the position of the ore is to be determined by calculation, the *sine method* must be employed.

Where no ore is present, the needle is acted upon by two forces, one of which is due to the fixed magnet, and the other to the horizontal component of the earth's magnetism. These two forces acting simultaneously, the needle takes up a position in the direction of their resultant. Then if α is the angle of deviation, and H the component of the earth's magnetism, the following formulæ are obtained:

$$\begin{aligned} \text{for the tangent method: } H \tan. \alpha &= K_1, \\ \text{for the sine method: } H \sin. \alpha &= K_2, \end{aligned}$$

in which K_1 and K_2 are constants, so long as the size and position of the magnet remain unaltered. If these constants are known, the actual value of H may be found from the magnitude of the observed angle by either of the methods. If the constants are unknown only the relative value of H may be found. When observations are made near an iron ore field, in both formulæ H must be replaced by R , the resultant of the horizontal component of the earth's magnetism and the magnetism of the deposit. The formulæ then become

$$R \tan. \alpha = K_1, \text{ and } R \sin. \alpha = K_2.$$

When the deviations are caused by the soft iron rod instead of by the magnet, somewhat similar formulæ are obtained; but the magnetism of the iron rod being due to induction, its intensity is proportional to the variations of the vertical components of the earth's magnetism. It follows that the constant K of each formulæ in this case must be replaced by a magnitude that varies with the magnetism of the rod. Observations with the iron rod indicate the inclination of the earth's magnetism; whilst observations with the bar magnet serve for determining the horizontal components of the same terrestrial force. Consequently, by combining the two methods, it is possible to find out the vertical components of the magnetic force.

In order to survey an ore field, it must first be divided into squares with sides 100, 50, or 25 feet in length. Then at every angle of these squares, the deviation must be observed with the magnet and iron rod. Similar observations must be made on ground free from iron, and so far distant from the ore field that the influence of the ore is not felt. It is also advisable to determine the magnetic declination for each point of observation. This may be done by directing the sights along one of the lines that has been set out, and reading the bearing, after the fixed magnet and iron rod have been removed. Observations must also be made along the magnetic meridian north of the supposed ore pole to determine where the north-seeking end of the free needle changes its direction from north to south, or whether it invariably points towards the north.

When these determinations of declination, horizontal intensity, and inclination have been carefully made, and the angles obtained noted on paper divided into squares, lines are drawn for each of the three series of observations, exhibiting equal declination (isogonic lines), equal intensity (isodynamic lines), and equal inclination (isoclinic lines). This is done in each case by joining the points for which equal angles were obtained. The curvature of the lines is drawn as naturally as possible, care being taken to avoid sharp bends. The curves of inclination and intensity thus constructed are closed, and have an approximately circular or elliptical shape, provided that a single isolated ore mass is being dealt with. They are grouped around two points. The one at the north is where the greatest angle of deviation was found, whilst that at the south is where the smallest angle was obtained. Between these two groups of curves is an open curved line representing the neutral angle. In this neutral line the intensity is the same as if no ore was present. The straight line joining the points where the greatest and smallest angles were obtained passes over the centre of the ore mass, and indicates the direction of the magnetic meridian of the ore field. Directly beneath a point in this line, in a vertical ore bed, the greatest mass of ore occurs. The rule that most generally holds good in searching for iron ore is, that the ore mass is to be found immediately beneath the point where the magnetic meridian cuts the neutral line.

The isogonic lines consist of concentric ovals placed, as a rule, symmetrically on both sides of the meridian. From the shape and position of these curves useful indications may be obtained regarding the position of the ore pole, and the shape of the deposit.

TIBERG'S METHOD.

The instruments employed by E. Tiberger consist of a new magnetic instrument for determining the inclination, a plane-table, and a sighting instrument. The inclination instrument consists of a round box $3\frac{1}{2}$ inches in diameter and half an inch deep, fixed in two square brass frames with $3\frac{1}{2}$ inch sides. At its circumference it has a graduated ring, and in the middle a magnetic needle 2.36 inches in length. Its axis is at right angles to the plane of the box, and rests upon two agate supports. The needle can thus move freely when the instrument is placed horizontally or vertically. The instrument differs from other instruments for determining inclination in that the centre of gravity of the magnetic needle is a little below its horizontal axis when the instrument is in a vertical position. The needle is compensated for the vertical force of the earth's magnetism by a piece of wax fastened to its south-seeking end. The instrument is provided with a

spirit-level for horizontal adjustment, and with a ring, by means of which it can be suspended vertically. The sighting instrument is a brass plate about a foot in length, provided at one end with four square flanges to receive the inclination instrument for horizontal measurements. At right angles to this square, there is a groove in the plate with a sliding receptacle for the bar magnet required for horizontal measurements. Four folding sights are attached to the plate in such a way that their lines of sight form a right angle. The instrument, consequently, can be used as a cross-head. Two special sights are added for levelling operations, and the instrument is provided with a circular spirit-level. The plane table employed is of the usual form.

The observations for vertical measurements are made at the surface with the plane-table or by hand. The inclination instrument is fastened to the plane-table, levelled, and turned until the needle points to 90° . The instrument is then raised with the ring at the top, and placed at right angles to the magnetic meridian, and the angle indicated by the needle observed. The same operation has to be done by hand if the plane-table is not available. When the ore appears to be deep, or when the horizontal intensity is powerful, recourse must be had to the plane-table.

The formula for calculating the vertical intensity G is—

$$G = K \tan. v,$$

in which v is the angle given by the needle—that is, its deviation from the horizontal—and K a constant varying in different instruments from 0.75 to 1.4 of the earth's horizontal magnetic force. Lines of equal vertical intensity may thus be constructed. In magnetic plans it is usual to employ a blue colour for positive intensity, and a red colour for negative intensity. The accuracy attainable with this method is from 0.2 to 0.1 per cent. of the earth's magnetic force in central Sweden. With the plane-table 150 to 300 observations may be made per day, and 450 to 500 by hand. For each ore field surveyed the needle must be compensated afresh, and a preliminary magnetic survey made. The field is then divided into squares, with sides 40 feet in length. The base line is as near as possible in the middle of the field, and parallel to the direction of the strike of the deposit. In making the survey observations are made every 10 feet, and in some cases every 5 feet, in the immediate vicinity of the ore, and every 20 to 40 feet or more when further distant from the ore. The general rule is to make as many observations as may be required to indicate what the appearances of the curves will be. Heights are estimated by the eye, or by a preliminary levelling with the sighting instrument, and the more important topographical details are noted.

The maximum of intensity is generally presented by the point where the ore is nearest to the surface. It may also be situated between two adjacent deposits—in which case the intensity decreases, at first slowly, or not at all, and then comparatively rapidly. The distance to the centre of a vertical ore-bed may be taken as at least 0.7 of half the breadth of the north-polar attraction. This rule is, however, not very trustworthy. The vertical distance of the plane of observation from the upper ore pole is equal to the horizontal distance of the point where the needle deviated most from the horizontal from that where $\frac{1}{2}$ of the greatest intensity was found. It is also equal to $1\frac{1}{2}$ of the distance of the point where the needle dipped most from that where half the maximum was found. The latter rule is the best.

Sometimes these calculations enable an opinion to be formed of the relative values of two similar ore beds. For two deposits of a similar character, situated at least 30 feet beneath the surface, it may be assumed that the deposit, for which the product of the greatest intensity and the polar distance is the greater, contains the larger quantity of ore for the same length of deposit. If the polar surfaces of the two beds are limited this product must be replaced by the square of the polar distance.

A good idea of a deposit may be formed from the appearance of the curves of intensity. Regular, long extended, elliptical curves, enclosing a long but narrow district of greatest intensity, always indicate a regular lenticular mass. More circular curves may indicate a segregation of ore if the intensity decreases regularly. Irregular curves indicate more or less irregular deposits.

In exploring for courses of ore in the mine, a base line is marked out in the level, and observations made every 10 feet at least. At each station, three observations have to be made:—1. To determine the direction of the total horizontal intensity by means of the sighting instrument, the deviation of the magnetic needle from the base line being observed. 2. To determine the magnitude of its force by means of the bar magnet. 3. To determine the vertical intensity by means of the inclination instrument. Vertical measurements must also be made at the top and floor of the level, and for this purpose the instrument may be held in the hand. On neutral ground at the surface, the horizontal force of the earth's magnetism and the direction of the earth's magnetic meridian must be determined. The results of all the observations are represented on paper, along the base line, as arrows showing the horizontal forces of the magnetism of the ore at the points of observation. If all or part of the arrows are directed towards the same point, there the ore may be assumed to be. The ore would be at the level at which the observations were made, if the vertical intensity is negative. When the arrows approach in front or behind, the plane of observation is above or below the magnetic centre of the ore. When the vertical intensity is positive, the ore may be above or below the plane of observation, always assuming that a more or less vertical ore mass is being dealt with.

CONCLUSION.

From the sketch of the new methods given above, it will be seen how admirably the principles of terrestrial magnetism have been applied in Sweden for the exploration of iron ores. The results are not only of scientific interest, but also of great practical importance. To illustrate this, it may be mentioned that by applying his method, Tiberger has discovered very important deposits of ore at the mines of Langban and Sikberg. Some interesting results, too, have been obtained by Professor Thalén, who has been able, with the magnetometer, to determine the various percentages of powdered iron ore and microscopic fragments of magnetic minerals occurring in the various beds of clay at Upsala. In the same way the order of succession of beds of iron-bearing can be determined. It appears therefore that accurate magnetic surveys would be of great value to the geologist, as well as to the miner. The value of the improved methods in the exploration and development of iron ore districts cannot be over-estimated, and probably a great future is in store for them in solving questions of stratigraphical geology in districts containing magnetic rocks.

The Bristol Iron Mines.*

Although it is strictly within bounds to speak of the Bristol district as a comparatively new one, it is also a fact that ore has been known to exist in this region for some years. In his "Notes on the Iron Ores of Canada and their Development" (1874) B. J. Harrington, B. A., Ph. D., commented as follows:

"During the winter of 1872-73 several openings were made in deposits of magnetic ore on lots twenty-one and twenty-two of the second range of Bristol, Pontiac County, Quebec. The ore here forms a series of beds, interstratified with reddish syenitic gneiss and glistening micaceous and hornblende schists. The thickness of what appeared to be the most important and the upper-

between E. and W. and E. 30° N., the angle of dip being usually high.

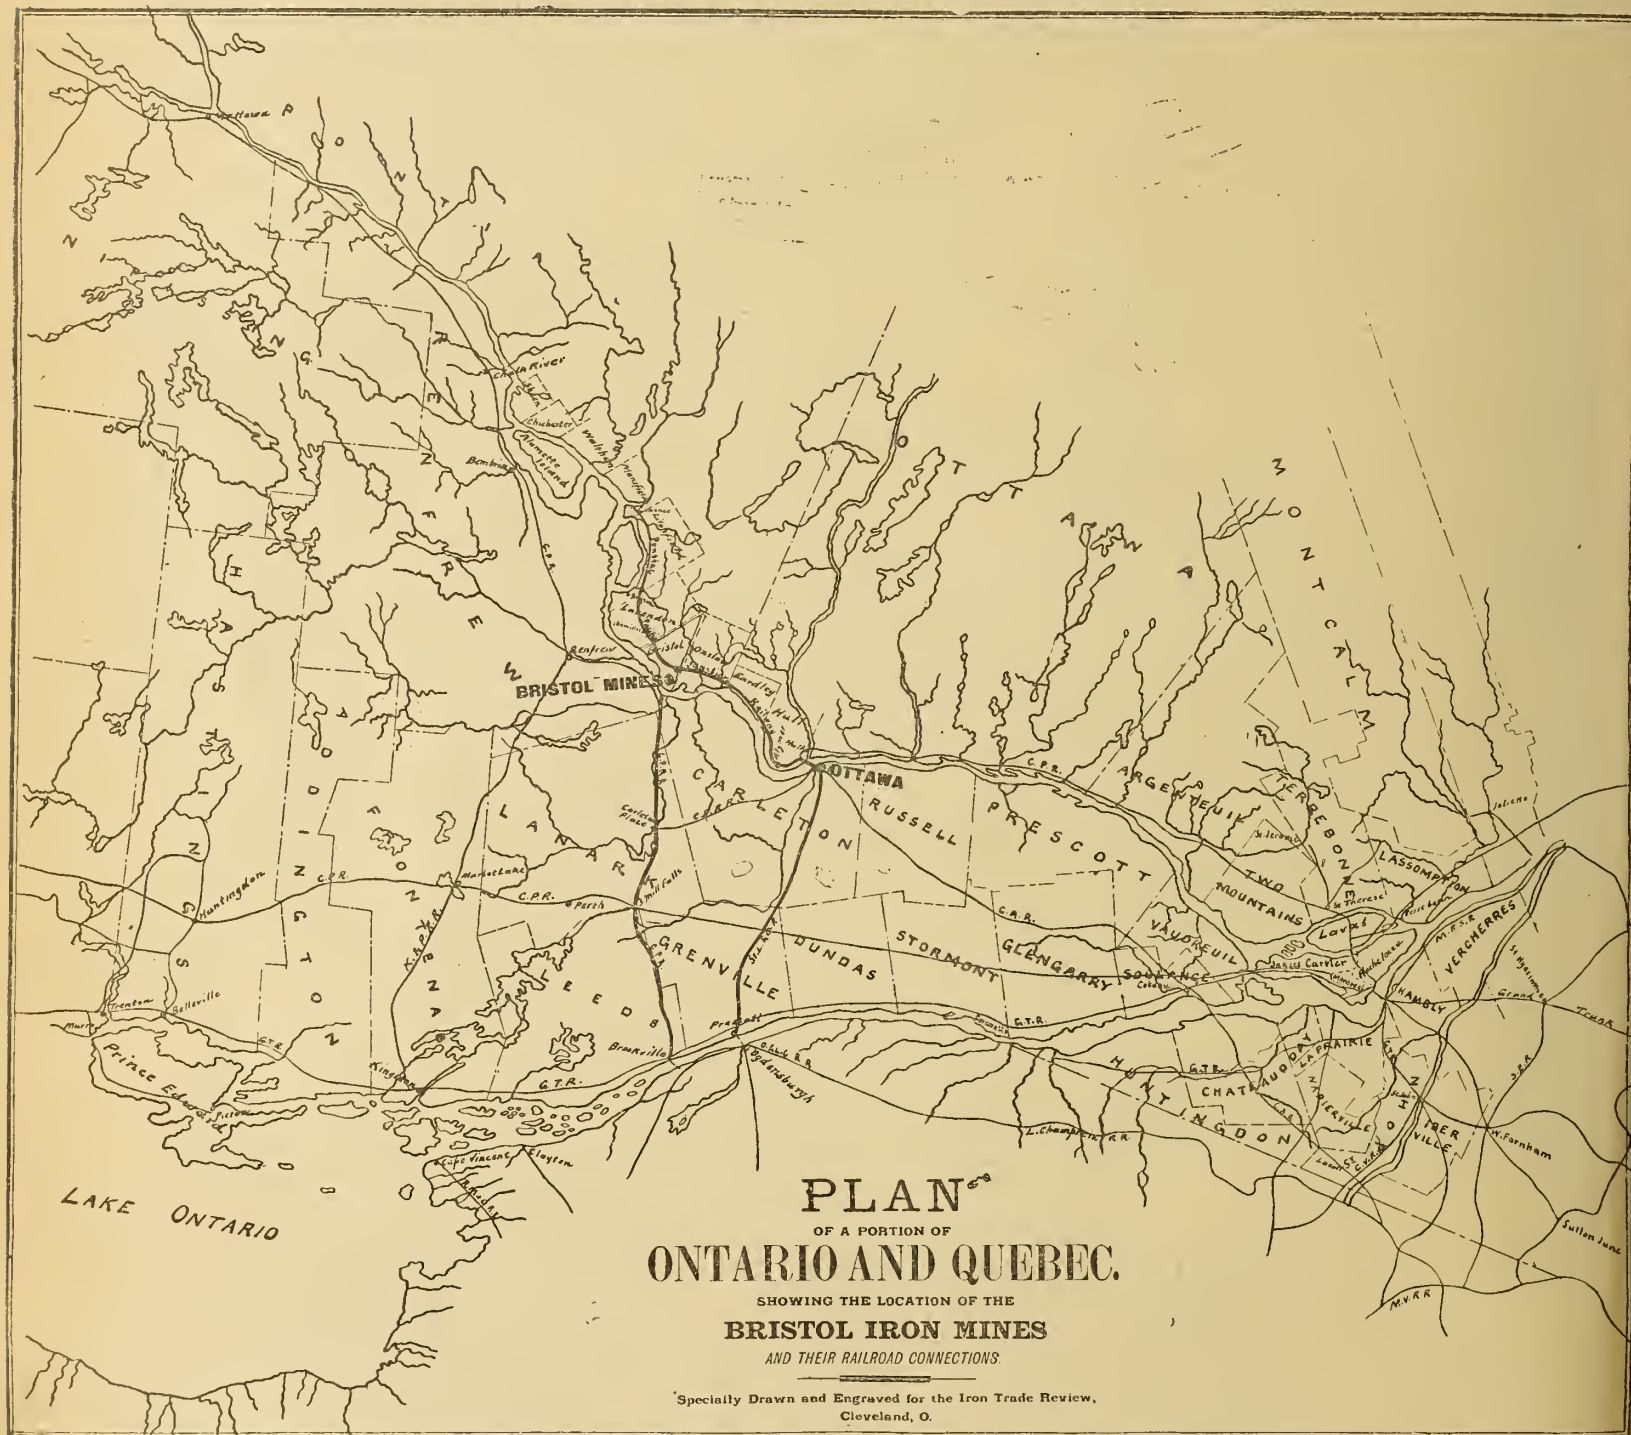

"The ore, though generally called magnetic iron ore, is really a mixture of crystalline magnetic and hematite, with a streak ranging in color from reddish to black. The specimen selected for analysis, and regarded as representing the average of what had been taken from the largest excavation up to July last, was rather finely granular, of a dark steel-grey color, and readily attracted by the magnet. The streak varied from reddish-brown to black in places. Scattered here and there through the mass were nests of pyrites, some of them nearly a quarter of an inch in diameter, and with the glass disseminated grains of quartz and calcite could be seen. The specific gravity was 4.32, and the results of an analysis as follows:

Iron as peroxide.....	45.81
Iron as protoxide.....	11.28
Iron as bisulphide.....	1.28

Total metallic iron.....	58.37
Sulphur.....	1.46

"Combining a sufficient quantity of the peroxide of iron with the protoxide to form magnetic oxide, we find the ore to be a mixture of magnetite and hematite, in the proportion of 46.72 of the former to 33.22 of the latter (1.40 : 1).

"The Bristol mine was first opened in January, 1873, and work continued with eight or nine men until September. The ore raised during that time amounts to about 4,000 tons, and still lies at the mine awaiting shipment. At the time of my visit in July, the largest

most bed could not be ascertained at the time of my visit in July last, as the opening upon it was nearly full of water; judging, however, from the quantity of ore taken out, the thickness must be considerable. Besides this bed, three others have been exposed by stripping; one of them was two feet thick, another only a few inches, but underlain by occasional small lenticular patches of ore, while the fourth appeared to be about nine or ten feet thick, so far as the small amount of work done enabled one to judge. The micaceous and hornblende schists in which the last mentioned bed occurs strike approximately east and west, dipping northward at an angle of only 35°. The general strike of the rocks as observed in the country for several miles east of the mines varies

Peroxide of iron.....	65.44
Protoxide of iron.....	14.50
Bisulphide of iron.....	2.74
Protoxide of manganese.....	0.11
Lime.....	0.60
Alumina.....	3.90
Magnesia.....	0.45
Silica.....	11.45
Carbonic acid.....	1.64
Phosphoric acid.....	traces.
Titanic acid.....	nene.
Water.....	6.14
Total.....	100.97

opening which had been made was 35 feet long, 24 feet wide, and about 20 feet deep, and from it about 1,500 tons (estimated) of ore had been extracted."

In 1881 the mine was in the hands of Mr. A. H. Baldwin, who also owned the Forsythe mine. Mr. Baldwin subsequently sold the property to Colonel Roberts, of Charlotte, and it was for some time operated jointly by that gentleman and Capt. C. C. Symonds, an old and experienced Cornwall (England) and Lake Superior mine captain. Colonel Roberts dying, operations were suspended until December, 1886, when the property was acquired by a wealthy and influential syndicate composed of the following gentlemen: Mr. Robert Blackburn, of Ottawa, retired merchant and extensive miner

and exporter of phosphates; Mr. Hiram Robinson, of Ottawa, President of the Upper Ottawa Improvement Company and one of the principal owners of the Kingston & Pembroke iron mining properties; Mr. Charles Magee, largely interested in Ottawa real estate and Vice-

property by the writer last week showed the following to be the present stage of development:

The property controlled by the syndicate consists of 400 acres, lying in Bristol Township, Pontiac County, Quebec, one and a half miles northerly from the Ottawa River. By the aid of the needle, with the revelations made by test pits, the locations and trend of the deposit have been quite accurately determined; and a careful

northwesterly and southeasterly. On the north vein is a test-pit 20 feet in depth, from which a considerable quantity of ore has been taken. The most active operations, however, are on the south vein. About the centre of the property is located the "Central Slope," now opened to a depth of 125 feet. Originally a shaft was sunk to a depth of about 60 feet, when rock was struck. The general dip of the rock was then followed for some 30 feet more when work in that direction was abandoned and a new start was made at a point about 45 feet from the mouth of the shaft and the slope continued at an angle of about 45 degrees, in order to maintain a skip-way. In opening up the new slope a "horse-back" about 12 feet in thickness was penetrated, after which ore in large quantities and of excellent quality was reached, and in this work is now proceeding. It is the intention of Captain Symonds, as soon as the lower level is intercepted, to open up a slope. About 20 feet below the opening of the shaft, drifts were driven in either direction for a distance of ten to fifteen feet, disclosing solid ore on both sides. The work of elevating the ore is at present performed by a small hoisting engine located at the mouth of the pit, but preparations are being rapidly made to mine on a much more extensive scale. In the large hoisting house, a frame building 35x70 with an iron roof, a first-class modern plant is to be found, consisting of an Ingersoll air-compressor 20x30, six Ingersoll drills, one 100 horse-power steel boiler, one 50-horse-power hoisting engine with two 6-foot drums, two 25 horse-power portable boilers, and one small hoisting engine. Adjoining the hoisting house is a blacksmith shop 20x30.

Five hundred feet southeasterly from the Central Slope is the east shaft. This shaft is 62 feet deep but is not at present being operated, the principal work being concentrated on the Central Slope. A large stockpile near by, however, shows ore of the same uniform

President of the Bank of Ottawa, and Mr. C. C. Symonds, above referred to.

With characteristic enterprise the syndicate began immediately to resume developments on the property where they were left off by Colonel Roberts. Captain Symonds was put in charge of the active operations, and the work already accomplished speaks volumes for his experience and common-sense. An inspection of the

traversing of the property with the needle tended to confirm the plan laid down by the owners in every respect.

There are, beyond doubt, two veins of iron ore—the north lode showing a width of 150 feet and the south lode a width of about 200 feet. These veins are from 250 to 300 feet apart and have been traced across the entire property of the syndicate. The general trend is

appearance as at the Slope. A short distance west of the Central Slope the vein seems to open out into a secondary seam terminating in a needle tests show that this seam, leaving the south vein, has a width of about 300 feet for a distance of about 110 feet in a southwesterly direction. Lying southeasterly from this vein or off shoot and connected by a narrow vein is the pocket referred to. This pocket is apparently about 350

feet long by 250 feet wide, and two test pits (one of them now being worked as a shaft, under sub-contract) fully confirm the indications of the needle. From the new shaft ore of even better quality than that at the Central Slope is being taken out.

The analysis presented in Mr. Harrington's paper, in 1874, though showing a very good quality of ore, scarcely does justice to the ore more recently taken out, as shown by the following analyses of picked specimens:

[By Dr. S. A. Lattimore, of Rochester (N.Y.) University]

Metallic iron.....	67.80
Silica.....	.02
Sulphur.....	none.
Phosphorus.....	none.
Titanium.....	none.

[By T. W. McKeon, of Youngstown, O.]

Metallic iron.....	66.50
Silica.....	5.50
Phosphorus.....	.0018

[By B. N. R. Richards, of New York.]

Metallic iron.....	62.15
Silica.....	8.12
Phosphorus.....	.0075
Sulphur.....	.97

While the above analyses present a fair idea of the richness of the ore, and while considerable quantities are to be obtained with little or no sulphur, the fact is to be stated, and is acknowledged at the outset, that the great bulk of the product is too high in sulphur for successful use in the blast furnace before being calcined or roasted. A fair statement of the average percentage of sulphur would probably place it at from 1.5 to 2 per cent. The problem before the syndicate has been from the beginning, whether to roast the ores at the mines or at the furnace. They have finally decided upon the former course, for the present, and have now on the grounds the castings and fire-brick for two calcining furnaces after the patterns of Taylor & Langdon, of Chester, N.J.

The Taylor-Langdon furnace consists essentially of a series of ore chambers surrounding a central gas distributing chamber and arranged to receive their supply of ore from a common ore chamber at the top of the furnace. The ore chambers are provided at the bottom with shutters and gates for regulating the drawing of the ore. In practice, the ore has to be broken to the size of a man's fist. Gas fuel is used, and the admission of gas is controlled by dampers, so as to maintain at the circulating flue—where it meets the air for its combustion—and oxydizing atmosphere as far as possible. Since the elimination of sulphur is imperfect, even at a high temperature, while the ore is in contact with gaseous products of combustion, the ore is withdrawn from such contact as soon as possible after it has attained the necessary temperature. The construction of the kiln is such that the workman can control the process by having access to the ore during the whole time it remains in the kiln, especially in the hot zone. By this furnace the sulphur has been reduced to 0.10 per cent. but it usually runs 0.30 to 0.40 per cent. The New Jersey magnetites, which are principally roasted in the Taylor-Langdon furnace, are very hard and dense, carrying from 2 to 5 per cent. of sulphur as pyrites, and become very sticky as soon as any attempt is made to roast them at a high heat. The Bristol mine ores, on the other hand, are of a rather soft and friable texture, easily freed from sulphur, yet not disintegrating under heat. This peculiarity has been demonstrated in the kiln, and was also shown in the heating of a piece of ore in the blacksmith's forge on the ground last week. The cost of Anthracite (buckwheat size) at the mine is \$5 per ton. Six tons of coal will calcine 100 tons of ore, and the product of each kiln is about 50 tons per day. This kiln is now in operation at Chester furnace, Chester, Pa.; Edge Hill furnace, Edge Hill, Pa.; Phoenix Iron Works, Phoenixville, Pa., and elsewhere, and is doing good work. The Bristol mine syndicate is confident that the cost of roasting can be brought under 55 cents per ton. It is worth while considering, however, whether it might not be economy to transport the raw ore to a natural gas region, or to a cheap fuel center like Cleveland, and there roast them before consumption.

An examination of the two maps accompanying this article will show that, with comparatively little trouble or expense, the district can be brought into direct connection with the great consuming centres of New York, Pennsylvania and Ohio. To the north, a distance of only 2½ miles, runs the Pontiac Pacific Railroad connecting with the Canadian Pacific and running into Ottawa, thence direct to Prescott or Brockville, on the St. Lawrence River. It is understood that the Pontiac Pacific is willing to run a switch to the mines upon certain conditions as to shipment. Another valuable connection would be by the Canadian Pacific direct, which could be reached by a tramway running southwesterly 1½ miles, thence across the Ottawa River by ferry to Braeside, on the Canadian Pacific, reaching the St. Lawrence at Brockville. At either of the above points on the St. Lawrence, barges and schooners can be loaded direct for

Cleveland and Lake Erie ports. Crossing the St. Lawrence rail connection can be had to New York and Eastern Pennsylvania furnaces. The distance to market are as follows: From the mines to Billerica, on the Pontiac Pacific Railway, 2½ miles; from Billerica to Ottawa, 40 miles; from Ottawa to Prescott, 51 miles; from Prescott to Cleveland, 412 miles; total, 535½ miles. The route by Braeside and the Canadian Pacific Railway is about the same. The distance of the Gogebic mines from Cleveland is 858 miles (60 miles rail, 798 miles lake). The Vermillion mines are slightly further, while Marquette and Menominee are nearer.

From data based on actual experience, as well as from propositions now in the hands of the syndicate, we make the following estimate as to the cost of mining and marketing the ore:

	Per Ton.
Cost of mining.....	\$.50
Roasting.....	.55
Handling at the mine.....	.15
Rail freight to the St. Lawrence.....	1.00
Loading.....	.25
Lake freight to Cleveland (including unloading).....	.90
Duty.....	.75
Agent's commission, insurance, interest, etc.....	.15
Total.....	\$4.25

Ore of this grade, free from sulphur, is now selling in Cleveland at \$6 @ \$6.50. With increased handling facilities at mine and river, the cost would be reduced to but slightly over \$4.00 per ton.

The gentlemen comprising the syndicate have embarked in the enterprise not as a speculation, but solely on business principles, and they propose to develop the property to its fullest extent. The mine is not for sale, but its product will be by next season. It is within the scope of the syndicate's plans to smelt the ore at the mines, but this is a matter for future consideration. The new Canadian tariff doubles the previous rate on pig iron, placing it now at \$2 per ton, and affords ample protection. The present consumption in Canada is equivalent to 250,000 tons of pig iron, leaving steel rails out of the question altogether; so that, under the new tariff, an immediate and steady home market is assured. With a continuance of the same intelligent and progressive management as in the past, there is no reason to doubt that the new district will soon take a most important rank among the iron producing districts of the Dominion.

*Reproduced with alteration and slight correction from an article published by the *Iron Trade Review*, Cleveland, Ohio. We are also indebted to the management of that excellent journal for the use of the plates.—Editor.

The following shipments of Canadian ore have been made from Montreal for month ending 31st July, 1887:—

A new company under designation of the United States and Canada Phosphate Mining and Fertilizing Company has been organized at Hallowell, Me., with a capital stock of \$200,000. Two hundred acres of mining lands have been purchased near Buckingham, and the new company proceed at once to mine phosphate and manufacture fertilizers.

A scheme is stated to be on foot in Montreal to open a new field for the utilization of phosphate. One of the proposals is to obtain possession of the Montreal abattoirs with a view to mixing dried roek with the tannage and thus produce at once a very powerful manure.

Advices from the Canadian phosphate mines continue satisfactory, the output continuing fully up to expecta-

tious. Prices in England and on the Continent range pretty much as previously, while the outlook for sales of Canadian crude phosphate in the United States market continues to improve.

The two lots which the Union Phosphate & Land Co. have lately opened up on Silver Lake give every indication of turning out well. A steam drill, hoisting engine and other improved machinery, along with a force of about twenty men, are employed. The Star Hill Mine is turning out its usual monthly output.

The output from the High Rock Mine for the past month will figure about 625 tons high grade ore. Most of this has been taken out of pit 2, which is undoubtedly one of the finest pits at present operated in Canada.

Mr. Wm. Pickford, sr., one of the owners of the mine, who has been residing on the property for several months, has returned to England.

Major Turnbull and Mr. Thomas Trimble, of Montreal, who are largely interested in the Templeton and Blanche River Phosphate Mining Company, paid a visit during the month to their newly acquired property at Templeton. They express themselves as much pleased with the outlook of the company.

The North Star Company have purchased a new 40 horse-power boiler which will greatly facilitate the further sinking of their shaft which has now reached a depth of 620 feet.

Mr. Franchot, manager of the Emerald Mine, informs us that the usual output of 500 tons was reached last month with a staff of about sixty men.

The mills of the Du Lievre Milling & Mining Company, at Bassin Du Lievre, are kept very busy grinding large quantities of lower grade ore from the various mines. We understand that the company are receiving large quantities from the Perth district.

Much dissatisfaction exists among the miners and business men with regard to the passenger service lately adopted by the Canadian Pacific Railway between Montreal and Ottawa. By the new arrangement visitors to the Capital from Buckingham must lose two nights and a day before they can return, while formerly they could transact their business and reach home on the same day. We understand that an endeavour will be made to effect a more convenient train service between the two points.

Operations are being conducted smoothly at the Little Rapids Mine. The energies of the staff have been directed to the ballasting and fixing up of the new tram line and other improvements on the property. Bush fires in the neighbourhood have proved troublesome, and numbers of men have been constantly employed for several days cutting down timber and taking other steps to remove the buildings on the property from danger. In consequence of these the output for the month has been somewhat below the average.

On Thursday, 11th instant, a representative of the REVIEW paid a visit to the Buckingham district with the object of visiting all the mines now in operation on the Lievre. Little Rapids was the first property visited, and here, through the courtesy of the superintendent, Mr. George R. Smith, we were taken down the shaft, which has now attained a depth of some 212 feet. A close inspection of the various levels revealed an immense body of high grade ore. We were next conducted to the engine and pump houses, where nothing but the newest and most improved machinery is being operated; the stores, cobbing houses, and the other buildings on the property were also visited. Everywhere one could not fail to be impressed with the careful, systematic and orderly manner which characterises the working of this mine.

It was our intention, on returning from the other mines further up the river, to have made a longer and closer inspection of this property, but as the sequel shows this was not to be.

In company with Mr. James White, of the Geological Survey, who has been located in the district during the summer making a topographical survey of the phosphate region, and Mr. A. May, of Ottawa, who had accompanied us on our visit, we started on our return to the Landing. Near by stood one of the ordinary box trucks used for carrying the ore over the new tram line, and to facilitate our progress, for the road was soft and slippery, we mounted this car, which, by the way was loaded with

rock, and started her down the hill. Mr. White was operating the brakes in front and the REVIEW man and Mr. May were standing on the small platform in rear. At first all went well, but on reaching the first grade the brakes, through some unexplained reason, failed to hold, and gaining impetus at every yard the car shot down the hill with terrific speed. With a roar like thunder we swept round curves and down grades in the most appalling manner, until about half way down the hill, fortunately on one of the best pieces of track, the car left the rails, and after running several yards along the ties crashed over on its side. The occupants were all thrown violently to the ground. Mr. White, upon whose foot the car fell, sustained a severe fracture to his right leg, was cut about the face and badly shaken. The REVIEW man was more fortunate, escaping with a simple fracture to the left arm and a little shaking up. Mr. May was uninjured. The wonder is that all three were not dashed to pieces. Intelligence of the accident was at once conveyed to Buckingham and five hours later Dr. Wallace arrived and had the injured promptly attended to. The thanks of the party are due to Mrs. Platt, who was unremitting in her kindly attention to the injured, and to the sympathetic band of stalwart miners who worked so hard for their comfort. No blame can be attached to anyone for the unfortunate occurrence.

The Du Lièvre is rapidly falling but no actual work has been accomplished on the new lock and dam at Little Rapids. The contractor has pitched his tents on the ground, built himself a "bathing house," and brought up some material; but the powers that be have set a "nigger on the fence" to show how such things are done, and NOT done.

On Wednesday 10th inst., a special meeting of the Ottawa County Council was held for the purpose of settling the dispute which has long existed between the West Templeton Township and the Canada Phosphate Company, relative to the payment of taxes on a proposed new road running through lots 16, 17 and 18, range 8, and which the company affirmed they would never use and could not legally be taxed for. On the other side it was argued that the township could not make a new road on the concession line, as a hill of sand would have to be excavated at an enormous outlay. The phosphate company own lots 16, 17 and 18, range 9, and as the township affirm should pay a proportionate part of the taxation. The question was debated for some four hours before the ayes and nays were called for, which, when taken, resulted in a tie. Mr. Cormier, as Warden, gave his casting vote in favour of the company.

The phosphate and other deposits discovered by Mr. John Frost in the rear of the Township of Litchfield, specimens of which he had examined by Mr. Obalski, the mineralogist, have been pronounced the best shewn him in Pontiac.

Mr. Alex. Johnston, who has purchased a half interest in the O'Brien Phosphate Mine, put in three blasts recently with the result that the mineral turned out better than was expected. He contemplates putting on a force of men this fall when the extent of the development will be ascertained.

Mr. Sharp has discovered phosphate on his farm in Bristol, specimens of which has been left at the office of the Crown Land Agent for examination by the mineralogist.

The simultaneous manufacture of these two valuable fertilizing products, assimilable phosphates and sulphate of ammonia, has been facilitated by a process lately patented by Mr. E. Salvoy, of ammonia-soda renown. It consists in adding to superphosphate of lime, during its manufacture, ammonia and carbonate of ammonia, so as to produce a complete manure in which the nitrogen is fixed without any additional acid. When phosphate of lime is attacked by sulphuric acid, almost insoluble sulphate and soluble monobasic phosphate of lime are produced, and this mixture constitutes the usual superphosphate of commerce. These two salts may be separated by filtration, or they may be left intermixed. By the new process, a very large portion of the acid employed for this purpose may be economized or recovered by combining this manufacture with that of ammoniacal salts, for, if ammonia be placed in presence of monobasic phosphate of lime, an insoluble bi-basic phosphate of lime and phosphate of ammonia are formed. The phosphate of lime obtained has an agricultural value equal to that of superphosphate, and in addition, phosphate of ammonia is obtained, which is very valuable for agricultural purposes. If it be preferred to obtain all the phosphoric acid as phosphate of ammonia, the phosphate of lime (bi-basic) is treated over again by

sulphuric acid. If it be preferred to obtain all the phosphoric acid in a state of phosphate of lime, the phosphate of ammonia is treated by a suitable salt of lime.

Nova Scotia.

A gold mine, known as the Hall Owens property at Caledonia, N.S., was recently sold to an American Company for \$25,000.

The Eastern Development Company (Limited) has received a diploma and bronze medal for its exhibits at the Colonial and Indian Exhibition held lately in England.

There is, says the *Critic*, very little new to report in regard to the gold mines of the Province. All the old properties are being worked to their utmost capacity, but new finds of value are rarely heard of. Coal mining is in a flourishing condition, and the Spring Hill Mines have just closed a large contract with the Grand Trunk Railroad. Nothing new has been received in regard to the opening up of the iron deposits under the stimulus of the new tariff; but the air is full of rumors of proposed works. We should like to see active operations commenced, as the summer season is now half over; and if something is not soon done, another year will have to elapse before smelting works can be built. In New Brunswick, the mining outlook is most promising, and new discoveries of valuable minerals are reported from several sections of the Province. The wild speculative period of mining has been passed over, and under wise and competent management, assisted by greatly improved mining machinery, profitable returns are the rule, and we hear of no failures.

The mines on Gold River are being worked as usual, but the water supply for crushing is short at this dry time. Quartz, however, of a good quality is being taken out, and will be all ready for the first rain, when we hope to hear of that mill taking lots of the precious metal from the quartz now being raised to the surface.

Quebec.

There is nothing new to report from the Villeneuve Mica & Mining Company's mines. The work of cutting and sorting the mica is being steadily pursued and the management at Buckingham is kept very busy filling large orders from Canadian and American consumers.

Ontario.

Our Sudbary correspondent sends us the following particulars of recent operations at the mines of the Canadian Copper Company:—At the Copper Cliff Mine there have been put in two 50 horse-power boilers, made by John Doty Engine Co., Toronto, which furnish steam for a small double hoisting engine, built by Webster, Camp & Lane Manufacturing Company, of Akron, Ohio, and one three drill air compressor, made by Ingersoll Rock Drill Company, of Montreal. A ten horse-power portable engine drives a Beckett & McDonald rock breaker, which has a capacity of crushing eighty to one hundred tons of ore per day. After passing through the crusher the ore and waste rock are separated. A two compartment shaft, with shaft house and rock house, are being built, the former nearly completed. At the Stobie Mine the earth and detached waste rock are being stripped from the surface, thus exposing the ore. A vertical shaft is being sunk to strike the vein at about 450 feet from the base of the hill, which has now reached a depth of 72 feet. At this mine a three drill compressor and one crusher are in operation, together with a small hoisting engine at the shaft. The company have secured the services of Dr. George Stewart, a late graduate of the Toronto School of Medicine, as physician and surgeon for the miners and their families. On Tuesday, the 2nd instant, the Hon. Alex. McKay, Mayor of Hamilton, Ont., with a party of about twenty aldermen of that thriving city, made a brief visit to the Stobie Mine.

The Nipissing Times will shortly contain a series of articles on Mineralogy and Prospecting from the pen of a distinguished mineralogist. The object in view is to enable its readers to discover for themselves the various economic minerals which are said to exist in abundance in the Mattawa district.

Local exchanges announce the discovery of anthracite coal on the property of Mr. Nix, a farmer, living about nine miles east of Campbellford. Samples were found by Mr. Nix some years ago, but he paid no attention to the matter until Dr. McCrea, of Campbellford, interested himself in the case.

We understand that the Kaladar gold mining property, owned by Napanee parties, has been sold for \$12,000. Mr. Peter McLaren, of Perth, is one of the purchasers.

Mr. N. J. Ritchie, president of the Central Ontario Railway, will shortly commence work at the Baker iron mine.

PORT ARTHUR DISTRICT.

The *Miner* has been incorporated with the *Weekly Herald*. The paper will hereafter be known as *The Algoma Miner and the Weekly Herald*.

The Rabbit Mountain Mine is still under course of development, under the management of Dr. Lehman, of St. Paul. It is only fair to say that had the company, which own this property, adopted the vigorous policy pursued by their neighbours at the Beaver Mine, they would to-day have probably as much ore in sight. Under Dr. Lehman the shaft at this mine has been deepened 100 feet, which gives a total depth of 240 feet. For the last 70 feet of this distance a fine streak of silver shown continuously along the foot wall of the shaft. Drifts from the shaft in both directions are being driven at the bottom, and at fifty feet above it, with most encouraging results.

Silver Mountain, east end, is looking particularly well at the present time. The west, No. 3, shaft has been sunk 125 feet and good silver struck. This is the shaft to sink which new machinery has been put down and recently got in operation, and they are now prepared with all the appliances to go down 1,000 feet. In this shaft the pay streak is 3 feet wide and assays show \$90 of silver per ton. In stope drift No. 5 the pit is showing up good about 30 feet down, and this, with the large amount of undeveloped ground to the west toward the new shaft, leads to the conviction that there is plenty of good ore to be had in Silver Mountain, east end. They are just now shipping in sacks the smelting ore to Liverpool. Capt. John Trethewey has resigned his position as superintendent of the mine and Capt. Thomas Trethewey takes his place, the change having gone into effect on the 1st instant.

The Ontario Silver Mining Company, of St. Paul, are working a short distance east of the Badger, and according to reports, are delighted with their investment.

The presence of R. G. Peters, of Manistee, Mich., in the city, and the knowledge that he is chief owner in the wonderfully rich Beaver Silver Mining properties, but lately developed, sent a News representative after him to glean, if possible, a few facts regarding his exceedingly profitable investment. It was learned that there are now 144 men employed at the mine, which is 28 miles southwest of Port Arthur on the Canadian North Shore of Lake Superior. The mine owners are now shipping away about \$10,000 worth of ore daily, none of which has a lower assay value than \$1,500 per ton, and much of it a great deal higher. Mr. Peters has with him a little fragment of native silver weighing 60 pounds, which has an assay rating of \$15,000 per ton. The property is being rapidly developed, and 350 feet of shafts have already been made, and 2,300 feet of cross drifting has taken place, with the result in every instance of increasing the visible amount of rich ore in sight. The gentlemen who own the mine are increasing the machinery and appliances for reducing the ore more rapidly, less expensively and with far less waste than heretofore.—*Duluth News*.

The prospect at the Queen Gold and Silver Mining Company's location is good, and all the developments only give more certain evidences of the value of the location. Mr. Kimball has made a big cut 20x20 feet on the junction of the two veins and here he intends to sink the shaft. From the shaft they will be able to drift four ways.

In the immediate neighbourhood of Port Arthur are vast deposits of silver and gold now being worked, and towards the frontier line is an extensive region of iron ore. The Port Arthur, Duluth and Western Railway will accommodate a number of these mines, and, passing through the iron regions, will connect with the Duluth and Iron Range Railway, forming a direct route to Duluth, St. Paul, Minneapolis, and the Northern

Pacific Railway. Within three miles of Port Arthur is Fort William, on the Kaministiquia River, navigable for ten miles, on which the Canadian Pacific Railway has extensive dockage and warehouse property. Port Arthur, with its piers, where the lake steamers arrive and depart with passengers and goods, and Fort William, where the freight traffic is transacted, have but a narrow mile or two between, and must be linked together as one city—the Port Arthur of the future.

British Columbia.

The Silkirk Mining and Smelting Company, of Illecillewaet, shipped their first car load of ore on the 25th ult., to the smelting works at Denver. The shipment consisted of fifteen and a half tons of tested ore, having an assay value of 2,120 ounces of silver. The company have the privilege of drawing on the smelting works for ninety per cent. of this value on its being forwarded. An assayer holding the confidence of the Denver company states the value of the ore, he having made tests that enable him to do so. On the lead nothing can be drawn until it has been smelted. The work on the four ledges owned by this company is progressing favourably, and it is hoped that in course of a short time they will be in a position to turn out ore at the rate of two or three carloads per week.

Hixon creek is still being developed, the company confining their efforts to sinking on the shaft which is constantly improving in quality of rock.

The Rock creek gold fields on the border are getting more prominent every day for the extent and richness of its mineral. The Amelia is one of the seventy-five or more locations about five miles from Rock creek on elevated table land. Two shafts are being sunk, one of them is down forty feet and shows a fine body of ore. A thirty foot cross-cut has been made on the other fifteen foot shaft and no foot wall is found. The surface cropings are rich with free gold and as it is penetrated it becomes rich in sulphurets.

Mr. John Ross, the well known railway contractor, has become the owner of a silver mine on Illecillewaet river, which promises to be very rich, judging from the assays that have been made from its ores. Mr. Ross has purchased two of the most improved crushers, and these will be taken out shortly and placed in position. The mine is distant about one mile from the railway track and is located away up on the steep mountain.

Mr. John B. Farish, of Denver, Colorado, a mining engineer who ranks among the first in America, has been retained by the British Columbia Milling and Mining Co. and the Island Mining Co. to examine their mining properties in Cariboo. It shows wisdom on the part of the above companies to retain a mining engineer of known ability, instead of trusting to one whose only recommendation may be cheapness. The B. C. and Island Mountain will thus secure positive information as to the proper treatment of their properties and though it is rather expensive at present, it is bound to prove the most economical in the end.

The Vancouver Coal Mining and Land Company's mine was discovered in the early days by the employes of the Hudson Bay company, and has been operated since 1851. Its coal has been used by the San Francisco Gas company for the past thirty years—a striking testimony to its merits. There are always several hundred men employed at the mine, which is one of the largest on the Pacific coast, and produces some of the best coal in the world.

The total area of the Wellington Estate, operated by the Vancouver Coal Company, comprises 2,417 acres. Messrs. R. Dunsomier & Sons have constructed a railroad a little over four miles in length, the greatest grade of which is 1 in 30, and the greatest curve 33; this bringing the mines to the water's margin. The daily output averages about 800 tons, 17,000 tons per month being shipped to San Francisco, San Pedro and other ports along the coast.

For domestic use the Wellington coal has been held in high favour from the earliest period of its introduction, for the reason that the most careful analysis has thus far failed to discover in it the slightest trace of sulphur, consequently it contains neither gas nor coke. For steam vessels and industrial purposes it is especially fitted, and to that use it is largely supplied. For more than eighteen years these mines have been operated upon a scale commensurate with the demand for the character of coal produced by them, supplying a rapidly growing trade from Vancouver Island to Mexico; and stretching far out into the Pacific Ocean to Hawaii, and yet the door of these coal fields is but fairly open.

Alaska.

Considerable excitement prevails in mining circles over the reported rich discoveries in the Silver Bay district near Sitka. The Lake Mountain Mill company has struck the ledge on the Lucky Chance location by continuing the same tunnel run under the management of B. R. Crowles. A quartz mill will soon be put in operation.

Mining developments and rich strikes from the Berner Bay district are constantly being reported.

The United States steamer Pinta has returned from Chilcoot to Sitka and reports everything quiet in that vicinity; also that the miners in the Yukon country are doing well so far as heard from.

NOTICE TO SUBSCRIBERS.

VALUABLE

Copper Mining Properties

— IN THE —

Eastern Townships

TOWNSHIP OF ASCOT.

- 1st. Clark Mine, Lot 11, R. 7 Ascot 187 acres
- 2nd. Sherbrooke Mine, part Lots 12 and 13,
R. 7 Township of Ascot 329 "
- 3rd. Belvidere Mine, part Lots 9 and 10, R.
9 and 10, R. 8 Ascot 292 "
- 4th. Mining Rights in same vicinity on 250 "

All of the above properties lie within $1\frac{1}{2}$ miles of the Village of Lennoxville, at the junction of the Grand Trunk, Canadian Pacific and Passumpsic Railways, and have been developed to a considerable extent, and veins opened 6 to 20 feet in width, yielding 3 to 5 per cent. of copper, also silver, and 35 to 40 per cent. of sulphur. These mines are only $2\frac{1}{2}$ to 3 miles distant from the City of Sherbrooke, and evidently are of the same class of ores found at Copelton, only four miles distant, owned and worked by the Orford Copper and Sulphur Company, and by Messrs. G. H. Nichols & Co., of New York, which have proved so remunerative.

TOWNSHIP OF ORFORD.

- 5th. Carbuncle Hill Mine, Lots 2 and 3 R. 14, and
2, 3, 4 R. 15, 718 acres. Same class of ore as is found
in the Ascot properties above described, but yielding a
higher percentage of copper.

TOWNSHIP OF CLEVELAND.

- 6th. St. Francis Mine, $\frac{1}{4}$ Lot 25 R. 12, 50 acres, with
dwelling houses, smith's shop, ore sheds and office, large
winding and pumping steam engine, with boiler, winding
and pumping gear, and about forty fathoms Cornish lift-
ing pumps complete, railway tracks, ladders, etc., situated
three miles from Grand Trunk Railway. A considerable
amount of mining work has been done at this mine.
A well defined vein richly charged with vitreous purple
and yellow sulphurets of copper traverse the entire
length of the property, five feet in thickness, yielding 8
to 40 per cent. metallic copper.

TOWNSHIP OF GARTHBY.

- 7th. Fifty-six lots of land, 2,938 acres. This prop-
erty for the most part is unexplored, but copper is found
on the greater part of the property. On one of the lots
a vein about twenty feet in width has been found.
Samples of the ore have yielded as much as 22 per cent.
of copper, being also rich in sulphur. Other samples of
pyrites from the same property, free from copper, have
yielded as high as 48 per cent. of sulphur. The only
drawback to this property is in its distance from the
railway, it being about four miles from Garthby Station,
Quebec Central Railway. A new line is chartered,
however, which, when built, will run directly through
the property.

TOWNSHIP OF ACTON.

- 8th. The Acton Mine, 100 acres, with engine, boiler,
pumps and appliances. Within three years after this
mine was first opened it produced nearly \$500,000
worth of copper. It is situated about half a mile distant
from the stations of the Grand Trunk and South Eastern
Railways.

- 9th. Brome Mine, part Lots 2 and 3 R. 4, 50 acres.
- 10th. Bolton Mine, two miles from Eastman Station,
Waterloo & Magog Railway, 400 acres.

The above properties formerly belonged to the Canadian Copper and Sulphur Company, and were acquired by the present owner at sheriff's sale, giving an indisputable title thereto.

The whole or any portion of the property will be sold at reasonable prices.

For further information apply to

WM. FARWELL,

SHERBROOKE, P.Q.,

CANADA.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein, either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same, but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth, and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall, within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt, it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should any person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes, reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees, in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench, creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:—

"Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR

Nov. 22nd, 1886.

Department of Inland Revenue.—An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue and the provisions of the foregoing sub-section have been complied with.

Every person who sells or offers or exposes for sale any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always that deficiency of one per centum of the ammonia, or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and entitled, "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

Notice to Contractors.

SAULT SAINT MARIE CANAL.

CONTRACTORS intending to tender for works of construction of the Canal proposed to be formed on the Canadian side of the Saint Mary's River, are hereby informed that Tenders will be received about JANUARY next, and that the most favourable time to examine the locality will be between the present time and the early part of November next.

When plans, specifications and other documents are prepared due notice will be given. Contractors will then have an opportunity of examining them and be furnished with blank forms of tender, etc.

By order,
A. P. BRADLEY,
Secretary.

Department of Railways and Canals,
Ottawa, 24th August, 1887.

Notice to Contractors

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Cobourg Work," will be received at this office until Thursday, the 6th October, for the construction of work at Cobourg, Ont., in accordance with a plan and specification to be seen at the Department of Public Works, Ottawa, and at the office of the Town Trust, Cobourg.

Tenders will not be considered unless made on the form supplied and signed with the actual signatures of the tenderers.

An accepted bank cheque payable to the order of the Minister of Public Works, equal to five per cent. of amount of tender, must accompany each tender. This cheque will be forfeited if the party decline the contract or fail to complete the work contracted for, and will be returned in case of non-acceptance of tender.

The Department does not bind itself to accept the lowest or any tender.

By order,
A. GOBEIL,
Secretary.

Department of Public Works,
Ottawa, 9th September, 1887.

NOTICE RESPECTING PASSPORTS.

PERSONS requiring passports from the Canadian Government should make application to this Department for the same, such application to be accompanied by the sum of four dollars, in payment of the official fee upon passports as fixed by the Governor-in-Council.

G. POWELL,
Under Secretary of State.

CONDUCTED BY B. T. A. BELL.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 15th of the month.

Address all correspondence, &c., to the Manager of the CANADIAN MINING REVIEW, Ottawa.

Ottawa as a Mining Centre.

It has been predicted that with the waste which for many years has been taking place in cutting and preparing timber in our forests, and from the want, of any systematised forestry regulations, the time is not very far distant when the lumber trade of Ottawa will shrink into very small proportions from the want of material, and that the large and costly establishments now employing, in this vicinity, so much labour and capital will materially curtail their operations, and practically suspend work on a large scale. The question which naturally arises is, how will Ottawa be affected by such a result? The country surrounding the capital is not an agricultural district compared with Western Ontario; and manufactures are only in their infancy. But just at the very time when this apparently bad outlook looms up a new industry appears and is assuming such proportions that there is every reason to believe it will, before many years elapse, become the leading enterprise of Central Canada, and afford employment for hundreds of busy hands. This industry is mining, and utilizing the product of the mine. The whole country north of Ottawa, wherever the Laurentian range of mountains is met with, possesses mineral wealth of one kind or another. Iron, plumbago, galena or lead, phosphate or apatite, asbestos and mica all are there, and in rich profusion. Few persons, beyond those engaged in mining enterprises, are aware of the richness of this section, and the wealth that has been lying at our very doors for years past, waiting only the hand of man for development. It is of untold value. The plumbago mines at Buckingham, a few years ago, gave every promise of becoming one of the largest industries

in Central Canada, but mismanagement and waste curtailed their operations, and the large crushing mill on Donaldson's Lake being destroyed in the great bush fires, which swept that section of the country, crippled that industry for the time being. These works, however, must eventually be utilized again, and the yield of the mineral is of so pure a quality and so easy of access that the only wonder is they have not again commenced operations. The enormous proportions the phosphate industry has assumed are well known both in Europe and at home here, and United States capitalists are investing largely in phosphate lands and phosphate operations. Not only, as at first, is the mineral mined and shipped, but crushing and pulverizing works are now in operation, and a demand for ground phosphate has arisen amongst the fertilizer companies on the shores of Lake Erie and elsewhere, which bids fair to shortly revolutionise the trade in rock phosphate by shipping only the ground material. Water power is the only cheap motor for works of this nature, and the mighty power of the Chaudiere Falls, which hitherto has been confined to the manufacture of forest products, will contribute its share to the development of mineral wealth as well.

The iron deposits which abound in this vicinity will prove as valuable in the near future as the gold-bearing quartz in the lands where the latter is worked. The iron of this district is known abroad for its excellent qualities, comparing as it does with the finest Sheffield steel, and one mine alone, in the townships of Templeton and Hull, is estimated by Professor Chapman to contain 6,300,000 tons, equal to a daily output of 100 tons of ore, or 60 tons of metal, during a period of a century and a half.

The iron deposits in Bristol are also now a centre of attraction, a number of capitalists having taken them in hand, and the only requisite to perfect a large iron trade in our midst, are smelting works, which time will certainly bring about. Taking into consideration these facts, he who reads the future will see visions of mining industries and their attendant factories supplanting the timber trade, when forest products will require to be handled miles away from their present location. As the demand for timber yearly drives the lumberman further and further up the head waters of the Ottawa and its tributaries, the mills will have to be located nearer to the place of production, and railway facilities for the transport of square timber and deals now penetrate the lumber district to such an extent, that the material loaded on the cars for Quebec, now passes by Ottawa in transit, instead of as formerly being floated here as a distributing point, where it could be rafted or sawn and shipped in its manufactured state. Where is the rafting, that only a few years ago, filled the bay below Parliament Hill with its industry? Where are the raftsmen whose

stalwart forms filled Sussex Street and Lower Town during the summer months? Gone with the advance of railways to other points which demand them. But the miner is gradually filling their place, and although his presence is not yet felt to any extent in the streets, yet we think the banks could tell us something of the large transactions done with him, and of the heavy drafts the pay roll of the mines requires monthly. The settlers on the Lièvre and Gatincau who were virually in the power of the large lumber firms, and who sold their produce to those firms for whatever they could get, are fast acquiring money from the demand the mines make for farm produce of all kinds; and this not for one firm only, but the competitive demand of the various mines enables the producer to ask and obtain a fair value for his hay, his roots, and produce generally. To the mining industries must Ottawa look in the near future for its trade, and although lumber has done much to build up the manufacturing industries of the Capital, mining will do still more, and be a permanent source of wealth, when the pine tree will be as scarce in the Ottawa district as it now is in Western Ontario.

Basic Slag as a Fertilizer.

For some time past the columns of *The Engineering and Mining Journal*, of New York, have been ventilating a very valuable discussion upon the merits and demerits of basic slag as a fertilizing agent. An editorial on the question concludes the matter thus:—

"The discussion upon the qualities or defects of basic slag is brought to a close in our present issue. The obstinate and studied silence with which it has been treated by European chemists leading us to infer that they feel somewhat insecure in their position, and like ourselves, regard the experiments hitherto made known as somewhat onesided, insufficient and unreliable. If the charges brought by Dr. Wyatt should be finally disproved, and the basic process worked in this country upon the promised large scale, our supply of raw phosphatic material will be increased and probably cheapened. If, on the other hand, the charges are sustained and verified, we shall simply be called upon to find a means of eliminating the precious element from its deleterious surroundings, and we have plenty of able chemists who will certainly solve the problem. Every thing comes to the men who can wait."

To us in Canada the question is one of comparatively little moment. With such vast deposits of rich phosphate in our possession, our farmers are in no way dependent upon this source of phosphoric acid. Like our contemporaries, we await further developments with calmness and composure.

A Suggestion.

The irregularity of apatite deposits has been the occasion of much disappointment to miners and the cause of heavy expenditure in exploration, which has been often fruitless. A wide vein of phosphate frequently narrows or pinches out entirely, but the few experiments that have so far been made towards deep mining go to show that the mineral will come in again if followed down. To sink a shaft usually costs about thirty dollars a vertical foot, and the

ordinary miner after spending money in going down a few feet without result is apt to abandon what might prove a richly productive lead. The diamond drill explores at one-tenth of the above cost, and if this were generally used miners could be informed whether outlay upon a shaft would be remunerated by the production of the mineral. A company owning a diamond drill might find a good field for operation among our apatite mines, or if the miners would combine and procure a drill it would be of great service in developing the industry and in preventing unprofitable outlay.

It has been suggested that the Government, through the Geological Survey, might properly conduct some explorations with the diamond drill upon public lands where there are good shows of apatite. If persistent deposits were found, the lands could be sold or leased on royalty and an ample return of the outlay would be obtained. If the search for apatite was not productive, other discoveries might be made or information be secured that would give valuable additions to the geological knowledge of our country.

Low Grade Phosphates.

Owing to the large production by various countries of phosphates containing from fifty to seventy per cent. of phosphate of lime, it has been found difficult to sell the lower qualities of Canadian apatite at remunerative prices. On the other hand there is a scarcity of high grade phosphates, and the demand seems abundant for all that Canada can supply. Whereas the price in England for eighty per cent. Canadian phosphate is now a shilling per unit or eighty per ton, the price for seventy per cent. is only eight pence per unit or four and six-eighths per ton, a difference of eight dollars per ton. It is, therefore, imperative that the quality of the Canadian product should be raised to the highest point in order to secure the most remunerative results. In many districts the impurities associated with the apatite are chiefly micaceous, and experiment has shown that by grinding the ore and by a carefully devised system of blowing and screening a large proportion of the mica can be taken out. In this way sixty per cent. phosphate has been raised to eighty per cent., and the mica saved has gone a considerable way towards defraying the cost of the process. The mica is so freely disseminated that to cob the ore by hand would be expensive and impracticable, whereas it is readily taken out by machinery at an expense of one or two dollars a ton and a saving of perhaps ten dollars a ton is effected. It appears as though the future of our phosphate industry must tend largely in the direction of producing high grade phosphates in a pulverized form, and the consideration of the proper machinery and the establishment of mills in suitable locations are among the most important claims upon the attention of our phosphate producers.

Our Mineral Exports.

The following official figures are given by the Department of Agriculture to show the value of exports, distinguishing Canadian produce from those of other countries, for the years ending 30th June, 1884, 1885 and 1886:—

1884.		
MINERAL.	Domestic.	Foreign.
Coal	\$1,201,172	\$157,177
Gold-bearing quartz, dust, nuggets, etc.	952,131
Gypsum, crude	160,607
Oils, mineral, crude and refined ..	7,546	192
Ore, antimony	4,855
“ copper	214,044
“ iron	66,549
“ lead	5
“ manganese	15,851
“ silver	12,920
Phosphates	453,322
Plumbago
Salt	17,408	37,387
Sand and gravels	14,152
Slate	11,445
Stone and marble, unwrought ..	52,478
Other articles	62,607	643
Total produce of the mine...	\$3,247,092	\$195,399

1885.		
MINERAL.	Domestic.	Foreign.
Coal	\$1,468,166	\$180,046
Gold-bearing quartz, dust, nuggets, etc.	9 9,007
Gypsum, crude	120,046
Oils, mineral, crude and refined ..	27,303	548
Ore, antimony	33,700
“ copper	246,230
“ iron	132,074
“ lead	36
“ manganese	22,790
“ silver	7,539
Phosphates	362,288
Plumbago	60	50
Salt	12,326	14,223
Sand and gravels	23,590
Slate	4,642
Stone and marble, unwrought ..	52,206	700
Other articles	127,534	1,366
Total produce of the mine...	\$3,639,537	\$196,933

1886.		
MINERAL.	Domestic.	Foreign.
Coal	\$1,416,160	\$182,717
Gold-bearing quartz, dust, nuggets, etc.	1,210,864
Gypsum, crude	114,736
Oils, mineral, crude and refined ..	30,957	214
Ore, antimony	38,320
“ copper	291,397
“ iron	23,039
“ lead
“ manganese	45,608
“ silver	25,137
Phosphates	431,951
Plumbago	1,481
Salt	26,749	13,204
Sand and gravels	23,195
Slate	4,552
Stone and marble, unwrought ..	61,950
Other articles	205,051	5
Total produce of the mine...	\$3,951,147	\$196,140

From these figures it will be seen that there has been an increase in the total amount of \$310,817, the principal progress being in gold, copper, phosphates and salt. The decrease in iron, has been considerable, but under the new protective tariff this industry is now rapidly regaining ground, and there can be no doubt that much improvement will have to be recorded by next year.

We Doubt It.

It is reported that the Hon. Mr. Mowat has returned from Europe greatly impressed with the wisdom of British Mining Laws and Regulations. The Ontario Premier has en-

quired closely into this matter, and it is said that as a result of his studies the office of his Commissioner of Lands and Forests, and particularly that section of it relating to the mining portion of the community, is immediately to undergo a thorough and complete overhauling. Political wirepullers and other carpet baggers, who have grown fat at the expense of honest prospectors, are no longer to have an unjust monopoly of the cream of Ontario mining lands. Acres heretofore given away to speculators and non-residents, without restriction as to residence and development, are in future to be reserved for those who, by their experience, will best utilize them for the good of the province and of the country. Indeed, we understand that the whole rotten system of Mining Laws now existing in Ontario is to undergo an immediate change for the better. Verily, if true, this will be “tidings of comfort and joy” to those who have so long contended against a code of laws which places a legitimate and immensely profitable source of revenue at the mercy of ignorant untrained persons and unscrupulous speculators, which discourages exploration, and deprives the worthy discoverer of minerals of the just reward of his labour.

Iron and Steel Institute.

The first volume for 1887 of that valuable work, the Journal of the Iron and Steel Institute, London, England, has been received. This book is so well known and has been so often described in these columns that it requires no further mention here more than to state that the very high reputation the work has acquired in past years as an excellent compendium of knowledge bearing on the iron and steel industries is fully borne out by the present edition. Besides containing full reports of the various papers submitted to the Annual Meeting of the institute in May last, Mr. Jeans, the editor, has gathered together and arranged in a very handy manner a vast amount of useful information. We are indebted to this work for several paragraphs in our present issue, and we hope in future numbers to be able to reproduce some of the larger papers for the benefit of our readers.

The Phosphate Trade of Canada.

By H. B. Small, Ottawa.

Continued from August issue.

Dr. Sterry Hunt, who has made a persistent study of the Laurentian rocks for upwards of thirty years, says the question of the continuity of the deposits is important. Veins fitting fissures in the rocks are sometimes continuous for great lengths and to great depths, but their extent varies. Inclined beds of the material, which once were horizontal sheets inclosed in strata that have since been folded or convoluted, should be as persistent in depth as in length and when traced in the outcrop for hundreds of feet may be expected to continue downwards as far, unless a turn of the enclosing strata brings

them up again to the surface. He urges, therefore, deep mining for permanent success, and the experience of the past year proves the correctness of his theory.

Until last year the majority of the workings were superficial, consisting rather of shallow pits or large quarries. The reason for this is traceable to the fact that apatite in its crude state finds a ready sale at all times, even in small lots of five or ten tons. Consequently farmers and others opened pits and trenches for the purpose of extracting what mineral was within easy reach, and with satisfactory results, but so soon as the opening attained a depth at which work became difficult from the want of appliances for hoisting, or from the inflow of surface water, the pit was abandoned for a fresh outcrop close by, and the same process was repeated. The very abundance and value of the mineral thus led to its careless and wasteful handling, and retarded for some time its legitimate growth. With the advent of capital matters assumed a different aspect, and the old unbusinesslike system of mining which characterized the first attempts in the Ottawa district has been abandoned, and deep mining is now engaged in with great promise of abundant returns. The investment of foreign capital, and the organization of powerful companies composed of men of practical business ability and intelligence, together with the introduction of steam power and improved machinery, economy in the management of the mines and the necessity of shipping only a high grade of purity, have now placed these works on a sound and permanent basis. One American company has sunk a shaft on their property nearly 300 feet deep, passing through several deposits of pure phosphate and following the connecting vein which narrowed at certain depths to no greater thickness than a man's thumb. At the depth of 260 feet they struck an apparently unlimited deposit on which they have continued working, running drifts laterally, and turning out a very large yield of apatite of high standard. Another company (Scotch) which only commenced operations last autumn have reached a depth of 100 feet with varying success till that depth was gained, when they came on an apparently solid deposit which they are now working.

The great advantage the Buckingham mines possess is their contiguity to navigable waters, the mines in the majority of cases being situated near the River Lievres. This is a slow, sluggish stream, very deep and only at one point in its course (known as the Little Rapids) where boulders occur and a ledge of rocks crosses the channel, is any obstruction offered to navigation. This is obviated by the use of flat bottomed scows carrying the apatite, being towed to the head of the rapids by a small steamer, where they are let loose to float over it, much in the same way as cribs of timber are sent over the Ottawa "slides," or over the rapids of the Ottawa and St. Lawrence rivers. At the foot of the rapids the scows are taken in tow by

another steamer which tows them to a landing at Buckingham Village, where a short branch line of the Canadian Pacific Railway has trucks waiting alongside the river, into which the mineral is transferred, and conveyed thence direct by rail to Montreal where the cars on arrival, traversing the line of docks, run alongside the vessel which is to receive their contents. The cost of floating the mineral down the river ranges from 30 to 50 cents, according to distance, the freight by rail to Montreal cost about one dollar and twenty-five cents per ton. Ocean freight ranges from three shillings to seven and six pence sterling, although there are times when from want of freight vessels will carry the mineral as ballast free of charge. The value of the crude material in Liverpool ranges from twenty-six to twenty-eight dollars, and from these figures it is easy to see what a profit there is in prosecuting this industry. But it is only by the outlay of large capital in developing and getting operations into thorough working order that this end is attained. The first year seldom leaves any margin, owing to the heavy outlay for plant, buildings, etc. But in the case of two companies, at least, one English and the other American, it is known that after the first year's outlay a dividend of 30 per cent. was declared and paid to the shareholders.

Care has to be taken that the quality shipped is of a proper standard, and not mixed grades. The qualities are known to the trade as firsts, seconds and thirds. The best quality averages from 80 to 85 per cent. of tribasic phosphate of lime, the general run of the apatite shipped ranging from 75 to 85 per cent. The basis of value for 80 per cent. mineral is about 1s. per unit, with a rise of one-fifth of a penny for each unit. To secure an even grade, dressing is resorted to under the name of "cobbing." This is necessitated by the intrusion of mica, pyrites, pyroxene, and carbonate of lime, all useless materials which have to be got rid of, except where large masses of pure apatite have been brought to the surface. Cobbing consists of the separation by hammers and hand picking,—an easy operation owing to the softness of the apatite as compared with extraneous substances—in a building known as a cobbing house partly open at the sides. On one side of this, through or around the interior of which solid tables or stands are located, are empty tram-cars or waggons, into one of which the refuse is thrown as broken off, whilst the apatite thus cleaned is thrown into another receptacle on the other side. Boys and old men are employed at this work, which no machinery has yet been found adapted to perform, and they earn from 50 to 75 cents per day, being paid mostly by piece work. In spite of this system large quantities of the mineral are thrown aside, which, with an improved system, will yet prove of value, much in the same way as the early gold workings of California and Australia yielded rich returns when their tailings were again worked over. A process has been discovered by which its originator claims that

after grinding and pulverizing very low grade material, he can separate the disseminated apatite from impurities, and if this turns out successfully there is room for unlimited manufacture, as the best of water-power for stamping and turning machinery is available at Buckingham.

The various forms in which the apatite of the Ottawa district presents itself are in crystals, sometimes of very large dimensions, in masses varying from compact to coarse granular; in strata of a lamellar texture, and in a friable variety which is abundant, known as a sugar phosphate. The colour varies, some being greenish, often clear sea green, bluish, red, brown of different shades, yellow, white and cream colour. The reddish brown, or nearly claret colour, is the hardest and most compact of all, taking only 12 feet square to the ton, whilst the green and other colours require 16.

Having now given an idea of what apatite is, and of the Ottawa district in which it is worked, it may be well to describe some of the larger mines in that locality. The Emerald Mine, one of the earliest opened, is one of the most productive, and is worked on thoroughly scientific principles. It is situated some 8 miles from Buckingham Village, is owned by the Ottawa Phosphate Company and has changed hands several times, each succeeding purchaser paying higher prices, the last sale clearing the owners over \$50,000, before any large works such as are now carried on there were undertaken. Drifts are now in the side of the hill to the main shaft, by means of which the refuse as well as the mineral are run out on a tramway. Little Rapids Mine is a very valuable property, some 3 miles north of the previous mine. A large number of openings have been made on the property all of which have yielded very good returns. Several deep shafts have been sunk and drifting carried on at various levels in the shaft with great success. This mine is at present owned by an Ottawa resident, Mr. W. A. Allan. The North Star Mine, owned by an American company, contiguous to the previous mine, is yielding handsome returns for the outlay on it, and it is here that the deep shaft of nearly 500 feet, previously mentioned, has been sunk to test the existence of the apatite. A small show on the mineral on the surface, only some 3 inches wide, was selected for the experiment. At a depth of 100 feet this increased out to 5 feet, shrinking below that to almost imperceptible dimensions, and at a still further depth expanding till it overlaid the whole width and extent of the shaft. The Glasgow-Canadian Phosphate Company last year opened a property near the former, and have two deep shafts already sunk, besides other workings, one of which penetrates the face of the hill. The shafts evidence the good results obtained by deep mining, and the company are in a fair way of meeting with rich returns for their expenditure. All the above mentioned mines lie on the eastern bank of the Lievres. Some 8 miles further up, on the left or western bank, are to be found

the High Rock Mines. These are amongst the most extensive of all, and belong to the Phosphate of Lime Company, of London, England, under the management of Mr. Pickford. The property owned by this company covers 1,200 acres. The profits of the three years, 1882-3-4, were sufficient to cover all the outlay and to admit of a dividend of 25 per cent. on the capital stock, besides setting apart \$10,000 as a reserve. Some 25 to 30 openings have been made on the property, and the deeper the works proceed the richer is the yield. Tramways along the face of the mountain, on which these works are situated, carry the refuse to points where it is easily dumped into ravines and so away from the site of any probable future openings. The offices, and buildings for the miners accommodation, are scrupulously looked after, and the company has provided a reading-room well supplied with books, papers and periodicals for their employees use when not working. The mountain is some 1,900 feet above the sea level, and the view from it is very fine, the Laurentian hills in all directions rising one above another till lost in the blue haze of the distance, whilst at the foot of the mountain is a natural beaver meadow, fringed with trees, and nestling as it does amongst the mountains gives an air of quiet and repose in contrast to the busy scene of the works going on above it. The number of men employed by this company ranges from 100 to 150. The Union Mines, belonging to an American company which owns 2,000 acres, are about one mile distant from the High Rock Mines. The work here has been reduced to a minimum by steam hoisting power, steam drills and all the modern appliances. The original capital of this company, \$100,000, was nearly all expended in plant, road making, and shaft-sinking, yet after one year's operations a dividend of 30 per cent. was earned and divided. A tramway runs along the face of all the openings and carries off the debris and waste rock to a ravine at the extremity of which lies a lovely small lake. The escarpment which forms the wall of this ravine shows the course of numerous veins of the mineral all trending eastward and running into the mountain, and the main works are carried on by literally quarrying the hill side, and cutting it away in solid masses. Three years ago on the site of the Union Mines there was nothing but rock and unbroken forest; to-day there are numerous dwellings, substantial offices and storerooms, tramways and good roads. The number of men employed here ranges from 100 to 125.

There are numerous smaller mines being worked all through the apatite district, especially in Templeton, where both Canadian and American capitalists are interested, and new mines are continually being opened. The description given of the mines above mentioned, however, shows sufficiently the magnitude of the various enterprises.

The following table of shipments, each calendar year respectively, from Montreal, of crude

Canadian apatite to be used in the manufacture of superphosphate abroad, gives a fair idea of the yield of the mines of the Ottawa district, as the greater portion of it is derived from them, the Kingston district only furnishing a small yearly amount.

1880.....	7,500 tons.
1881.....	10,307 "
1882.....	15,556 "
1883.....	17,160 "
1884.....	20,461 "
1885.....	24,876 "
1886.....	19,345 "

The question may naturally arise why such a commodity should be sent abroad to be manufactured when apparently it could be treated here and shipped in a condition ready for use, thus adding to our own industries. The reason for this, however, becomes obvious when we ascertain that the pyrites, out of which the acid for dissolving the apatite is not found in quantities sufficient to supply works on any scale within any reasonable distance of the mines. The cost of transport of pyrites would probably exceed the freight of the crude mineral to Europe, where, from the numerous chemical works existing, acid can be purchased far cheaper than it could be made here. Again our Canadian Apatite enters largely into competition with a lower grade phosphate from other quarters in the superphosphate works across the Atlantic. When a demand shall have arisen amongst our own farmers to compensate by the use of phosphatic fertilizers the soil for the loss it undergoes by the constant removal of crops, especially in districts where cattle raising is not largely carried on, superphosphate works may be started with a show of success, in spite of all difficulties. In his Report for 1883 the Minister of Agriculture remarks:—"experience goes to prove that for the production of cereals of every description as well as for the strengthening and renewal of worn-out lands, no available fertilizer is known that can produce such beneficial results as phosphate when subjected to a chemical process."

A curious feature in the apatite trade of Canada is that, although a very large amount of American capital is invested in our mines, almost the whole of their product finds its way to Great Britain, and that a large amount both of crude and manufactured phosphate is exported thence to the United States. There is every reason to believe that both these articles are Canadian produce reshipped, and the explanation given for this by Mr. Torrance, late of the Geological Survey staff, is that it is simply due to the conservatism of trade, as American dealers were in the habit of importing from Britain long before our Canadian deposits were worked, no efforts have since then been made to direct from here into fresh channels a trade which was commenced with the English market by men more familiar with that than with the American.

A wealthy American company has this year commenced operations at the junction of the

Lievres and Ottawa Rivers for grinding and pulverizing crude phosphate, either for acid treatment or for use in the pulverized state. These works are capable of grinding 50 tons per day, and an idea of the fineness of the work done may be formed from the fact that the powder has to pass through an 80 mesh bolt and blowers for separating the mica, leaving only a phenomenal quantity of that worthless and troublesome ingredient. The company have made arrangements by which the ground article can be delivered at cities along the south shore of Lake Erie, where all they can manufacture has been contracted for at a rate of freight of \$1.40 per ton. Hitherto those cities have been using South Carolina phosphate, the freight of which amounted before delivery there to nearly \$4.00 per ton.

In conclusion, Canadians are an agricultural class of people. The essentials for starting Canada's growth are force and material. The climate affords the forces, light, warmth and water; the material, lime, potash, ammonia and phosphate are at its very doors; and with these there is no reason why it should not be one of the most productive countries of the world, if it only uses in a rational manner the means which nature has provided for it.

Mining Developments on the North-western Pacific Coast, and their Wider Bearing.

By Amos Bowman, M.E.*

In the last two years I have had an opportunity to study the conditions of gold-mining in the far northwest of the Pacific Coast—in Cariboo district, British Columbia. That country joins Alaska in lat. 55°; and Cariboo district in lat. 53° to 54°, is three hundred miles north of the forty-ninth parallel. Having previously studied the auriferous deep gravels of California in lat. 38° (in connection with the California Geological Survey, in 1870-71), I am able to contribute a few facts, and comparisons having a wider and more general bearing. My last work in Cariboo district is in continuation of explorations geographical and geological, performed in 1876 and in 1882-3-4, for the Geological Survey of Canada, during which I have seen a large part of the Cordilleran plateau between the 39th and 54th parallels of latitude. The recent work in Cariboo was contributed to jointly by the Dominion and the Provincial Government of British Columbia, and carried out under the direction of Dr. Selwyn.

Before entering the gold region of the plateau proper, in British Columbia, I wish to say a few words in regard to coal and iron—the majority of our members, perhaps, being coal and iron men, connected with large enterprises in those lines, and naturally more interested in them. We have ocular proof in Scranton that coal and iron are elements which bring about solid and permanent developments. This well-built brick and stone city, with its population of 80,000 souls, has grown, we are told, in twenty-five years out of the underlying coal and adjacent iron. Unlimited industries, and the wealth and power of states, can grow out of coal and iron. We of the west are willing to admit that coal and iron, as collateral branches of the mining industry, are quite legitimate.

But we claim that the distribution and the

mining of the precious metals are important and significant in a wider sense. This industry has determined for the United States, and for Canada as well, the lines of immigration and national development. It wrought, in a period of twenty or thirty years, the permanent conquest by the Anglo-Teutonic races of the entire north Pacific coast, along with the dominion of the Pacific ocean. It lifted Australia from the condition of an antipodean colony and made it an empire. It is doing the same work in temperate South Africa. It may do a similar work in temperate South America. Mining of the precious metals accomplishes in the briefest space of history that which leaves its permanent mark on the course of events for a thousand years. It has built our transcontinental railways, and it is precious-metal mining that will make the Canadian Pacific Railway and its projected branches a profitable investment.

COAL AND IRON.

The Pacific coast in general, and the northwest coast in particular, is not lacking either in quantity, quality, or general abundance of coal and iron. It is true that our Carboniferous rocks were not deposited under coal-making conditions, and that Monte Diablo has yielded only an inferior coal. From these facts, with limited knowledge, the impression has gone forth that among the recently extinct and still active volcanoes of the western coast there can be no coal found worth mentioning. I do not consider that I am making any extravagant statement when I say that in British Columbia and on Puget Sound, in adjacent United States territory, we have a repetition of Pennsylvania, in our deposits of coal and iron.

Some mining engineers have called the coals "lignites," because they are not carboniferous coals; but they are genuine bituminous coals, and of first-rate quality.

We have coking coals, too; veins that make different qualities of coke. A coking coal has been mined for twenty years at Nanaimo, Vancouver's Island, and largely used for making gas in San Francisco and Portland. The coke from the retorts is well known in San Francisco. Coking coal exists on the Puyallup, and on Skagit river, in Washington territory, and probably in many other places. When coking coal shall be wanted in that country for smelting iron or reducing the precious metals, it will be forthcoming. The conditions of the country have not called for it, nor for a knowledge of it. The railways have only recently reached that far north and west.†

Anthracite and semi-anthracite have been reported from many different localities. I have seen specimens from Nisqually River, Washington Territory, and Queen Charlotte Island, British Columbia, and coals ranging from anthracite to semi-anthracite from half a dozen other localities. Bow River on the eastern flank of the Rocky Mountain range, yields a good anthracite.

In 1874 I was commissioned by the officers of the Central Pacific Railway Company, in California, to investigate the coal deposits adjacent to their lines in that State, and I was much impressed by two leading facts which were developed. The first appeared in analyses of the Pacific Coast coals in comparison with eastern coals. These analyses, which I tabulated on what I thought a large enough scale, in the number of localities represented, to establish the point, showed that the difference between what were commonly called "lignites" and the bituminous coals and anthracites, of the West and East, resolved itself simply into the

varying quantities of hydrogen which had entered into combination, owing to surrounding circumstances; and that it had very little to do with the age of the formation. Consequently, the application of the term "lignite" generally to western coals was a misnomer. We have also, however, the technical lignites, including the regular Bohemian brown coal. The second point noted was the very wide distribution of the lignites and coals of the Tertiary and Cretaceous formations in that State, wherever these formations extended; from which I drew the conclusion that by no means enough was known from actual development, at that time, regarding the presence of workable coal-veins in California to justify any sweeping condemnation of the whole as insignificant in quantity and inferior in quality. In this I differed from the opinions of others expressed, and current at the time.

I had seen enough to satisfy me that the conditions favourable to coal-making existed in localities wide apart, and at two different horizons, in the Tertiary and Cretaceous periods; for instance, at Monte Diablo and on Pitt River, in Shasta County, in rocks of the upper Cretaceous, and at Ione and Lincoln in middle Tertiary. Indeed, putting that together with subsequent developments, and with what I have myself seen, up and down the coast, and in localities all over the plateau of the cordillera in the latitudes mentioned, I cannot better describe the fact than by saying: "The process of coal-making in one or the other of these periods, although in disconnected basins, was almost universal." Along both shores of the island sea connecting with the North Pacific Ocean at Fuca and Johnston Straits, lies the coal-basin of the North West Coast already mentioned, in extent more than twice the width of the State of Pennsylvania—in the number and size of its veins the equal of anything I know of in the world. Iron is smelted in Oregon, Washington Territory, and in California; and many heavy iron deposits are known, but are of little present value, for the same reason as that which delays the development of our coking coal-veins.

The Cordilleran Plateau.—Without entering into further details on this subject, however interesting, I will, before passing from the coals to the precious metals of the Pacific Coast, briefly define and describe the plateau of the cordillera, to which I have several times referred. Its physical characteristics and its geological history are as important in connection with the coal-forming conditions of the two periods mentioned, as they are in the understanding of our precious-metal zone.

It was in 1858, beginning with the "Frazer River excitement," that the gold-hunting army of explorers began to turn backward from California to the eastward and northward, and so commenced the closer investigation of the cordilleran region. Very nearly simultaneously, between 1858 and 1861, or in general terms about ten years after the first movement to California, the solitudes of Puget Sound, of the Frazer River canons, of the eastern Sierra Nevada, of the Blue Mountains in Oregon, of Cariboo, and of the Rocky Mountains in general, from north to south, were broken by exploring or revisiting bands of prospectors. It was in 1861 that I joined this exploring army. I found out gradually that the mountainous region in question was neither a great basin, nor an irregular mass of mountains, but one great double range of broken chains, having a wide and general-level plateau between them, like two flanges on a wheel; that the plateau was characteristic, and an essential

part of the whole; and that it extended persistently with its accompaniments, and, as it seemed, indefinitely to the northward and southward.

As a whole, this great physical feature of the continent which has proved of so much importance to the precious-metal miner, appeared to be unrecognized; at least, it had no name until 1873, when I ventured, in a paper published in California, to call it (following recognized principles of nomenclature) the plateau of the cordillera, or briefly the cordilleran plateau. The term was precisely descriptive, and it has entered, I may observe, into some of the standard works on physical geography.

You will find in examining it on a globe that it extends not only from the southern end of South America to the northwestern end of Alaska, but that it continues in a direct line (scarcely recognizable on the map, on account of the difficulties of projection) across the Asiatic continent by way of the Yablonai, Altai, and western Tibetan ranges. Continuing in the same line, we find the plateaus of Persia and Arabia, and then the mountains of Abyssinia extending along the northeastern coast of Africa down to the Cape of Good Hope, forming the sea-margin of the African continental plateau. Branching or correlative plateau-ranges extend across Africa to the mountains of the Guinea; and across Europe by way of the Caucasus and the Alps to Spain; but keeping our main feature in view, we have little difficulty in recognizing it as one and the same orographic feature, which, having made America long, makes the Old World broad. I hope I am not travelling too far afield, in attempting to describe the principal characteristics of the cordillera, but so far, I think, we have solid footing, viz., that wherever seen in the direct line of continuation, the most remarkable feature of the mountain ranges in the world, is marked by its characteristic intermediate plateau; and by this token we may know it. Not the least noteworthy feature of the chain of plateaus I have been describing, is the fact that it divides that hemisphere which is nearly all land, from the other hemisphere which is nearly all water.‡

It is quite beyond my range to speculate concerning the causes of this feature, but it is not irrelevant (having found it so far-reaching), to ask the question, whether or not the causes were cosmical?—an inquiry involving glacial theories not entirely disconnected from problems of placer-mining.

Having looked at the plateau chain at large, we are prepared to consider what it is in detail, and in what respects this knowledge concerns the miner.

In alluding to the coal, I did not mention in so many words that the coal-forming conditions which existed from middle Cretaceous to middle Tertiary time, extended along the Pacific coast for thousands of miles upon the flanks of this line of plateaus. Its accompanying shore-sediments enter fiords of the Cretaceous period now far inland; formerly at sea-level, now presenting cliffs of pebble conglomerate six thousand feet above it, and along the eastern as well as the western flanks; while those of the Tertiary period, independently of the Cretaceous, lie in the positions of lake-basins covering scattering almost the entire plateau of the cordillera, at least in the north.

Rising of the Plateau.—A remarkable thing happened about the time our first Pacific coast coal was forming. It was nothing less than the first rising upward of this plateau of the cordillera. Its geological history, however

simple, has grown upon this very slowly. Geologists had to investigate it piecemeal, before they could put their observations together. And so it is all along the line.

To be continued.

The Canadian Iron Trade.

In a paper read before the recent gathering of the American Institute of Mining Engineers, at Duluth, Mr. J. H. Bartlett, M. E., of Montreal, said: There are two reasons which make the present time an appropriate one to direct attention to the field offered for enterprise in this direction, the first being the very favourable reports of the experts who examined and reported on the Canadian exhibit of minerals, particularly coal and iron, at the Colonial and Indian Exhibition, held in London, England, last year; the second and more important reason being the recent changes in the Canadian customs tariff inaugurated in May last. The tariff is now generally two-thirds of the American tariff, in addition to which the government, in order to encourage the manufacture of iron, grants a bounty upon pig iron made in Canada out of Canadian ore. In a paper presented to the Institute at the Halifax meeting, the writer gave a review of the various attempts to manufacture iron in Canada. The facts then presented were not such as to offer much encouragement to anyone to embark in similar enterprises under the conditions then existing, but, happily, these conditions are now changed and an early development may be anticipated. It will be remembered that the various provinces now forming the Dominion of Canada were only confederated in 1867, previously they were all separate and distinct colonies, each with its own fiscal tariff, and having only their own small market. Even after confederation the customs tariff was simply a revenue, not a protective tariff, until the year 1879 when the first effort was made in this direction, and an import duty of \$2.00 per ton was imposed on pig iron, whilst previously it had always been admitted free of duty, but the iron section of the tariff was very incomplete. As Canadian iron workers wages are regulated by Pittsburg wages, it is impossible to compete with Belgian, German and English manufacturers whose wages are on a much lower scale, unless sufficient protection is afforded. With one single exception all the attempts to manufacture iron in Canada have been with the use of charcoal as a fuel, and many of the attempts were made early in the century, and the operations were of very small dimensions. The only furnaces which have been successful have used bog iron ore and have made only a few tons of iron per day. A great bar to the trade has been a want of information regarding the extent of the market to be supplied. This difficulty has been to some extent removed, the writer having collected and tabulated the statistics of the Canadian iron trade for all the years since confederation, so that it is now possible to see what has been required in the past and to estimate what will be necessary in the future. For a young though large country with a small population, the amount of iron and steel consumed in Canada is remarkable. In the year 1878 a greater money value of iron and steel was imported into Canada than into the United States; and not making any iron of our own, the value of our consumption and imported iron and steel, per capita of the population, is always many times as much as the value of the imports per capita into the United States. The total balance of trade against

Canada up to the year 1886 was \$381,000,000. The total value of the imports of iron and steel during that period was \$253,250,000, from which it may be assumed that the balance of trade would have been in our favour had we made our own iron. The average annual value of our iron importations is about fourteen million dollars. The average weight of the rougher descriptions of iron and steel such as pigs, bars, plates, sheets, rails, etc., being about 250,000 tons in addition to which the weight in the imports of castings and forgings, hardware and manufactures, machinery and engines, etc., is very considerable. In almost every province iron ore is found in abundance and the provinces which have not coal have an abundance of timber fit for making charcoal. We possess the only deposits of coal on both the Atlantic and Pacific shores and in both Vancouver island and Cape Breton the coal seams run out under the ocean. In both these provinces of British Columbia and Nova Scotia, nature has been prodigal with deposits of various descriptions of iron ore of very good quality, and with plenty of flux all in the immediate vicinity of the coal fields. San Francisco is largely supplied with Nanaimo coal, and the blast furnaces in Oregon get most of their iron ore from Texada island in British Columbia. The eastern cities of Portland and Boston are supplied with some of their coal from Nova Scotia, and it would appear possible also to supply iron ore to eastern furnaces from that province. In New Brunswick both coal and iron are found. In both Ontario and Quebec there are immense deposits of the finest quality of iron ores and an unlimited supply of charcoal timber. In Manitoba there is iron ore and they have about 15,000 square miles underlaid with coal. In the North West provinces, the great future wheat producing country of the continent, there are deposits of iron ore reported, but the country is so vast that no special explorations have been made for it. They are, however, working a large deposit of anthracite coal at Anthracite, N. W. T., of a quality which compares favourably with the best from Pennsylvania, and there are 500 square miles of this section. The climate of this country is cold, but there are 50,000 square miles of it underlaid with coal of good quality and it is easily reached and worked, seams estimated to yield from five to nine million tons per square mile.

MISCELLANEOUS PARAGRAPHS.

Iron Ore in Nova Scotia.—Mr. E. Gilpin, in his *Report of the Mines of Nova Scotia*, reports the discovery of iron ore at Grand Lake, Halyan County, and in the Long Island district, Cape Breton County. Here the outcrop of two deposits of red hematite was opened. The ore was found to be of excellent quality and as much as ten feet in thickness. The deposits are situated very favourably on the side of a high hill and only a few yards from deep water.

A Remarkable Water Wheel.—The water-wheel that runs the works of the Sagadahoe Fertilizer Company, at Bowdoinham, Me., is probably the only one of its kind in existence. It is 27 feet in diameter, with a foot of its rim out of water at high tide. The spokes are wide and set diagonally, like the vanes of a

windmill. It turns eighteen hours of the day by tide power, running one way with the flow, the other with the ebb. With one foot fall of the tide, this wheel gives about fifty horsepower. It has been in use since 1691.

Relation of Coal-Dust to Mine Explosions.—Mr. Arthur Watts, Bede College, Durham, referring to a former letter to *Nature* in which he suggests that keeping the ventilating air current saturated with aqueous vapour might prove the most effective way of rendering the dust in coal mines innocuous, has, he says, been since shewn to be practicable in a South Wales colliery. Since then he has considerably extended his research, with results that confirm the conviction expressed in his letter, that many of the most disastrous colliery explosions during the last seven years in the northern portion of England have been practically dust explosions, and, therefore, preventable; that the rough method of watering the floors only, or the floors and sides, of the mines is delusive, since it leaves the most dangerous dust undisturbed, the upper and flocculent dust; and last, that probably the reasons why dust in dry pits does not explode more frequently are now within grasp. To this latter conclusion he writes:—"That every firing of a shot that is accompanied by flame in a dry pit does not produce an explosion is well known; that *sometimes* such firing of a shot *does* is unhappily also well known. That the local presence of gas, even in small amount, is sometimes the reason of this is universally acknowledged. That the amount and condition of the dust present (even in the practical absence of gas) is at other times the reason is now believed by many. Setting aside the *amount* of dust, which every one will allow must be an essential factor, and also the varying energy which the shot, blown out or not, develops, let us look at the other conditions. The temperature and hygroscopic state of the air current is one most important factor, and consequently the concomitant temperature and hygroscopic state of the dust traversed by such current. Beyond this, the *degree of fineness* and the *constituents* of the dust will have much to say in the matter. The finer the particles the more readily will they ignite, and more completely will they place their substance under the influences present. Thus ordinary screen coal dust will not ignite when a common match is lighted and applied to it, but it will when finely pounded in a mortar. Now the dust resting on the banks and upper portions generally of the ways will invariably so light and burn when dry, although the constituents vary greatly in different pits and in different seams of the same pit. What are the ordinary *constituents* of coal dust? Two, perhaps three, important substances, and others unimportant; important, as being inflammable in varying degrees; unimportant, either from their inflammability or from their excessively small amount. The three important are mother of coal or *dant*; coal, and certain coloured bodies, probably *spores*. The unimportant are shale or other stone dust, iron pyrites, lime flakes and incidentals, as animal and vegetable matters, and the results of the wear and tear of the haulage and winning apparatus, &c. Dismiss these last, as only one needs attention, the shale; and that special, not general. *Dant* lights most readily; the red end of a used match is often sufficient to fire it, and their burns itself out whether resting on wood or on stone. Burned in a retort it loses little weight, and the fumes it gives off will not ignite. Now this *dant* is largely present in upper and

flocculent dust, reaching in some specimens even 70 or 80 per cent. Dant clearly, therefore, is not itself dangerously explosive, yet it is admirably fitted to act the part that tinder use to do, when it handed on the spark from the flint and steel to the old fashioned brimstone match. Coal forms a considerable part of all upper and flocculent dust, and constitutes the great mass of the bottom dust along intake haulage roads. Coal dust (got as free from dant as possible) when pounded very fine ignites with some difficulty, burns at first somewhat fiercely and with considerable smoke, but generally goes out leaving a portion of the heap unburned. Placed on an iron plate, and burned by heating the plate, it threw off scintillations, its fumes readily took fire, and forty grains of dust were reduced to one grain of ash. In a report it gave off first much smoke which would not light; soon, however, the smoke lessened, when its fumes lit and burned with a long bright flame. Such coal dust is manifestly capable of producing an explosion. Under favourable conditions it can produce a considerable amount of illuminating coal-gas, whose presence would convert the air current into an explosive mixture. Therefore, adopting the former simile, as the dust is the *tinder*, so this coal is the *sulphur match*, as the shot flame or other initial cause is the *spark* struck from the flint and steel.

The Cost of Boring Petroleum Wells.

—Mr. C. D. Wilder, of Chicago, in a recent report on the natural gas and petroleum deposits of the United States, gives the following as the cost of boring petroleum wells in the neighbourhood of Lima, Ohio:—

Outfit, consisting of lumber for sills and braces, used in derrick works and for wheels.....	\$375
Engine, boiler and fittings.....	750
Total.....	\$1,125

The cost of putting down the well is, on the average, about one dollar per foot, there being a large amount of shale, slate and sandstone, and but little sandstone present. Even in an untried country, wells may be bored at a contract cost of \$2 per foot, for any depth without reference to the nature of the rock.

British Mineral Production.—From the annual reports of the Inspectors of Mines to Her Majesty's Secretary of State, just issued, we learn that the total quantity of minerals produced throughout the various districts of the United Kingdom, during the past year, was 170,006,959 tons, of which 157,511,482 were coal and 8,862,648 ironstone, the rest being fire-clay, oil shale and other minerals, being a total decrease of 3,217,001 tons compared with the preceding year, the decrease of coal being 1,832,936, and of ironstone 1,245,964 tons; 210,665 tons of mineral were wrought for every fatal accident, and 178,391 tons for every death, as compared with 214,651 and 150,620 tons respectively in the preceding year.

Canada Called to Account.—Canada has been called to account by the Mother Country for her temerity in seeking by higher import duties to build up an iron and steel industry worthy of the name. English iron and steel manufacturers, alarmed at so radical a change, asked the Colonial Secretary for information on the subject. Canada's answer, in the form of a report of a committee of the Privy Council of the Dominion, is direct and to the point. In-

deed, so direct and pointed is it that the *Colliery Guardian* is led to exclaim that "if there were any doubt before, no doubt can be any longer entertained that Canada is resolved upon having her own iron and steel industries." Well, it does have that appearance, truly. And what, we may ask, is the objection to that? The Privy Council declare that Canada possesses in an advantageous position abundance of iron ore, fuel and all the requisites for the manufacturing of iron and steel, and that she is "compelled in self-defence, as against America, to adopt a tariff policy in some measure approximating that to the United States in order to protect domestic industries and to develop the natural resources of the Dominion." She also pleads that in the steps taken by the Canadian Parliament to foster the manufacture of iron and steel and to place the industry on a firm foundation at the outset, "Canada is but following the methods adopted by Great Britain, France, Belgium, Germany, the United States, and other countries which have succeeded in promoting this great industry." This is certainly a cogent argument, however idly it may fall upon the ears of Free Trade Great Britain, and we cannot but admire the pluck of the younger country in taking a stand so much at variance with the generally recognized sentiment in England and at the same time so in accord with the experience of the United States in respect to industrial growth.—*Iron Trade Review*.

Application of Electricity to Mining Operations.

—There are several advantages inherent to electric method of transmitting power which render it very suitable for mining operations. With the view of contributing to a greater familiarity with electrical methods among those engaged in superintending mining operations, Mr. F. J. Rowan, in the *Transactions of the Mining Institute of Scotland*, has compiled a very complete record of the various installations which have been actually carried out. The following are the instances quoted of electrical transmission of power in mines:—(1) Pumping in Trefalgar Collieries, and at Thallern Colliery. (2) Winding, at Trefalgar, at Thibaut shaft, St. Etienne, at Péronnière Colliery, and at the Blanzly collieries. Haulage at Zankerode Colliery, and at Benthén. (4) Ventilation at Zankerode Colliery, at Trefalgar, and St. Claude, near Blanzly. Other application illustrating generally the electrical transmission of power are referred to, and comparisons between the various systems of transmitting power are instituted. These comparisons show that electrical methods have no cause to fear competition either as regards cost or efficiency. The longer the distance and the greater the amount of power to be transmitted, the more favourably does electrical transmission compare with other systems; but for this reason it has had a worse chance in early attempts than it would have had if its efficiency were greater on a small scale of distance and power.

Discovery of Semi-Anthracite Coal in British Columbia.

—A large deposit of Semi-Anthracite Coal is reported to have been made at Martin's Creek in the Kootenay District, B.C. It is described as follows:—If the reader imagines himself walking from west to east along the trail which follows the course of the creek, he will have the steep rounded hill immediately to his left with the well defined strata of yellowish grey sandstone dipping towards him at an angle of

thirty degrees. The first coal seam which he will come to, and which is almost on the trail, is the "Peter Seam." This has been opened up by driving in a tunnel for thirty feet and then laying bare the hanging and foot walls. It shows fourteen feet of pure coal, without a sign of shale or dirt. The hanging wall is grey sandstone, the foot wall a dark shale. A short way up the hill is No. 1 seam, on which the face has been cleared away to show the walls. Here there are three feet of pure coal, lying on four feet of coal with a little shale mixed with it. Not many feet above this is No. 2 seam, on which the face has been opened so as to show the walls. Here there are five feet of pure coal lying on two feet of coal with a slight mixture of shale. About fifty feet above this is No. 3 seam, on which the face has been opened as before, and here we have five feet of good coal, mixed with a little shale here and there. Not many feet above this is No. 4 seam, showing seven feet, of which five are pure coal and the remainder coal and shale. We now descend to the trail again, and here directly on the trail itself we have the "Jubilee seam." On this a tunnel has been run in for fifty-five feet and then the walls exposed. It shows thirty feet of clean, pure coal, without a sign of shale or dirt, and below this, five feet of coal and shale mixed. About eighty feet below the "Jubilee" is another seam, showing nine and a half feet of coal. About fifty feet below this is the "William seam," which is now being laid open, and which twelve feet of coal shows above the foot wall and the ranging wall has yet to be reached. All these seams have been found within a distance of 700 yards and within a period of two months, so that it is not too much to expect that more seams will yet be discovered. The course and dip of all the seams are the same, and the strata is remarkably regular and well defined. There is no appearance of a "fault" for many miles around. In all the seams the walls are similar and the coal has the same appearance to the eye. It may be described as being very black and shining, with a brilliant resinous appearance; does not soil the fingers; brittle, but becomes harder as depth is reached; powder jet black; hardly acted upon by nitric acid; no appearance of sulphur; burns with a bright clear glow and little smoke, and leaves very little ash; has been used for pointing and tempering the "picks" with excellent effect.

Stamps and Stamps.—As an illustration of the difference between stamps and stamps, for the benefit of inexperienced investors in mining properties, the following official statements of the work of the El Callao Gold Mining Company, of Venezuela, may be of interest: The company has two mills of 60-stamps each, one built by a good firm of engineers but inexperienced in mining machinery, the other supplied by Messrs. Fraser & Chalmers, of Chicago, representing the best modern designs and workmanship. Both mills are run under one management, and the old mill has been much improved over its original condition. Old 60-stamps crushed 31,770 tons in 48½ weeks; cost, 2460 francs a ton. New 60-stamps crushed 29,000 tons in 25 weeks; cost, 860 francs a ton. New 60-stamps will probably crush 60,000 tons in 51 weeks. The rock is hard gold quartz, and the above figures will show one of the little, unsuspected aids to success in mining investments, which prove that there is a difference even in stamp mills, and that economy in first purchase of machinery is not necessarily a good policy.—*E. and M. Journal*.

Journalistic "Rot."—In a voluminous issue of 21st August the *Globe-Democrat* stuffs its readers with the following rubbish under the head lines:—

A LIFE OF ROMANCE.

A Successful Miner who has had his
Share of Adventure.

Once the Owner of the Comstock
Lode.—A Quarter of a Cen-
tury's Experience in
Mexico, &c.

Including the portrait of the hero whose adventures we are told "almost suggest the great improbabilities of Mr. H. Rider Haggard." This romance fills three columns, of which more than two-thirds constitute, as it were, the vestibule leading to the miraculous discovery of the chief of "lost mines of Mexico," the "Realto," in the heart of the mountains of Sonora, 140 miles from the nearest railroad, worth "untold millions" as shown, we are told, by the remains there found, "ranged in a semi-circle about a clear and powerful spring which burst from living rock * * * of seventy *arastras*, the circular pit used in primitive times for the crushing of ores." And at the mines upon the cone of a mountain reached by a roadway "hewn out of the solid rock that must have cost \$20,000," were found "two enormous chambers cut out of the rock, in the quartz floors of which shafts were sunk," but these were found so "choked with drift and vegetation" that the discoverer says he had no means of exploring them; nor was any dump pile to be found. Neither does it appear that any ore was seen—or any other evidences of a mine, we repeat, than some chambers cut in the quartz, several unexplored shafts and a semi-circle of seventy *arastra* beds. Merely upon such meagre indications, the hero of this story rushed to Gerichi and there officially announced and located the mine, and a week later was on his way to the United States, in some part of which he found a shoal of fat gudgeons out of which to form a stock company with a capital of \$3,000,000 and with a view, ultimately, out of their spare capital, to build a short railroad of only 140 miles over the mountains and barancas of Sonora. Such a cheap trifle as a 50-stamp mill with a plant of other reduction appliances, including smelting works, are to be taken out and set up at once and Mr. Power, the fortunate discoverer, left St. Louis for the Realto mine, we are further told, on the 20th August, to superintend these works, after which, we presume, he will pay some attention to the lesser detail of ascertaining whether any ore of any description is to be found: or, in other words, whether there is a mine there to be worked.

Prospecting.—When one is prospecting for quartz, writes Mr. G. C. Swallow, he wants a good eye for the indications in the rocks and for the fragments of quartz lying on the foot hills and mountain sides as he travels over them. A stray piece of good looking quartz will challenge his attention as a fragment from some lode. When such a fragment is found, the first question is, "where did it come from?" Is it water-worn and rounded, or angular with sharp corners? If water-worn or rounded it has traveled by stream or glacier, and the prospector must seek its lode above on the line of such stream or glacier. Ores have thus been traced to their source for hundreds of miles. But for gold and silver quartz in these mountains, the source of these stray specimens must be sought at the gulches on which they are

found. If the specimen has not been worn and rounded and has sharp angles, it has not traveled far from its lode, which must be sought above in the mountain side. It may be traced by following a line of like specimens up to their source. Where the line of specimens ceases, the prospector may expect to find the vein, by the croppings or other indication of the lode. If the rock is bare this part of the work is soon done; but if covered up, it must be cleaned off by sinking a shaft and following the indications, or fragments of quartz. When the lode is found, the work of the prospector is finished and the development begins. Such a discovery is called a "prospect," and the holes dug to discover it are called "prospect holes," or "prospect shafts." Prospecting for placer gold is generally more laborious; but it keeps the prospector more stationary. When he finds a gulch that suits his notions, he sinks shafts to bed rock and tests the gravel as he goes down by washing and panning it. Experience in mining and a knowledge of glaciers are most useful in prospecting a gulch and its benches or "bars" as the miners call them. It is generally very easy to prospect a "bar," but there is great difficulty in prospecting a gulch or valley where the water is abundant. There are many gulches where there is every reason to believe the gravel on bed-rock is very rich; but the bed-rock water is so abundant those gravels cannot be easily reached and prospected. To remove this water and enable the prospector to test the gravel and bed-rock, is often very expensive, as many of our miners can testify from hard experience. Expensive hydraulic machinery is sometimes necessary to remove the water. Streams and even considerable rivers are at times turned from their channels for the purpose of working the gravel and sands in their beds.

The following shipments of Canadian ore have been made from Montreal from 10th August to 3rd September, 1887:—

Date.	Shippers.	Ship.	Destina- tion.	Tons.
Aug. 10	Lomer, Rohr & Co.	s.s. Navarro...	London	107

It is thought that the output from the High Rock Mine for this month will be in the vicinity of 540 tons, the greater portion of this having been mined from the large show in pit No 11, which still holds out as good as ever. The company has over 2,000 tons of first-class ore ready for shipment, but on account of the very low state of the river at present the management are unable to get their ore over the Little Rapids. Mr. Pickford, sr., with a gang of men constructed a dam at the right chute

in the hope of raising the water on the left bank which would allow their scows to get over. Their labours were, however, rendered futile by the logs from the drive which destroyed the dam, and it now looks as if the company will have to wait for rain.

The low water is also hindering the output from the North Star Mine.

There is nothing to report from the Union Mines. Work is being conducted smoothly, and the output for the month promises to be fully up to the average.

The new opening made in the beginning of the month on the south side of lot 6, at the Little Rapids property, promises to be one of the best of the many fine shows on the property. The superintendent is about to place a boiler and engine at the new opening in order to assist in the workings. An air pipe will also be run in from the Air Receiver in order to work the drills. The shipments for the month amounted to 180 tons of high grade ore.

Three shipments of ore from these mines during the present season have averaged 84.66—a highly satisfactory result. This is the best average we have yet heard of from a three shipment lot.

Mr. Jas. White, of the Geological Survey, who was injured in the tram-car accident last month at Little Rapids mines is progressing satisfactorily. He is still at the Protestant Hospital, Ottawa, under the care of Dr. Horsey, who has set the broken limb in Plaster of Paris. Mr. White hopes to be able to be removed to his private quarters in the course of a day or two. The *Review* man has now fully recovered and has resumed work.

Captain Henwood, the Superintendent of the Emerald Mine, has been the lucky finder of what promises to be an unusually fine show, for during the past month a fine vein of ore, thirty-four feet in length and four feet in width, has been uncovered. In colour it is a very light green and somewhat different to any of the ore hitherto found on the property. The output for August was 600 tons.

We are informed that work has at last commenced on the new lock and dam at Little Rapids. Such an improvement is very badly wanted, particularly at present when the water is so low that the miners are prevented from shipping their ore down the river.

English prices for high grade phosphate are firm, upwards of 1,000 tons having lately been sold at 1s. for 80 per cent. with 1½d. per unit rise. Freight is about 6s. to Liverpool and 8s. to London.

There is nothing new to report from the mines of the Anglo Canadian Company at Otty Lake. The Du Lievre mills, at Buckingham, are grinding some of their phosphate, and succeed in taking out a good deal of mica by their bolting process.

At Blackburn's mine there is a large quantity of ore in sight. The management are making extensive preparations in timbering to secure further economy in working.

Interesting Statistics.

The following figures show the mineral exports, domestic and foreign, from 1868 to 1886:—

1868.....	\$1,446,857	1878.....	\$2,816,347
1869.....	2,093,502	1879.....	3,082,900
1870.....	2,487,038	1880.....	2,877,351
1871.....	3,221,461	1881.....	2,767,829
1872.....	5,326,218	1882.....	3,013,578
1873.....	6,471,162	1883.....	2,970,886
1874.....	3,977,216	1884.....	3,247,092
1875.....	3,878,050	1885.....	3,639,537
1876.....	3,731,827	1887.....	3,951,147
1877.....	3,644,040		

MINING NOTES.

Nova Scotia.

According to official report the following is a comparative statement of the production of coal, iron ore and manganese ore during the Province for the years 1885 and 1886:—

	1885.	1886.
Coal.....	1,352,205.....	1,502,614
Coke made.....	30,185.....	31,601
Iron ore.....	48,129.....	44,388
Manganese ore.....	353.....	427

At Bridgewater Messrs. Ramey, Mulock & Co., who have two properties containing one hundred areas, on which they have been working for some months past, have opened up two large gold-bearing leads, measuring $5\frac{1}{4}$ feet and $2\frac{1}{2}$ feet respectively. At least three other leads not yet developed run across the property. These properties situated as they are, right beside a main highway, only two and a half miles from Bridgewater, and with a large water-power not half a mile distant, are evidently very valuable.

New Brunswick.

The interest in manganese mining is still on the increase, and steps are now in progress looking to the final sale of the Stockton Gold Mine on Smith's Creek road, at a handsome figure.

In the Dutch Valley, on what is known as the Glebe property, Mr. W. N. Gould is making an excellent showing, and the manganese is of a very superior quality. Shipments from the property will soon be made. The owners are well satisfied with the expenditure they have made in this locality.

Major Markham, of the Markhamville Manganese Mines, still continues to ship large lots of this material to the United States and English markets. The Major is well-known in mining circles, and takes a deep interest in all mining matters of a satisfactory nature.

Dr. A. H. Chandler, of Dorchester, N.B., in connection with some friends, is making very satisfactory developments on a gold property at Renfrew. The specimens they have on exhibition are certainly of a very valuable nature, and bid fair for the opening of a remunerative mine.

A preliminary examination of the silver and lead mine at Elm Tree, in Gloucester County, N.B., has recently been made, with a view of placing it into the hands of capitalists. The chances are that this property may yet pan out in good shape.

The work on the New Ireland Copper and Silver Mine in Alberta County is still continuing. An examination of the property has recently been made by a competent expert connected with one of the prominent gold mines in Nova Scotia. The prospects are, it is said, good for a sale being affected.

A Mr. McLean, of Charlotte County, has lately acquired and partially developed a large body of iron pyrites in that County, said to be suitable for the manufacture of sulphuric acid. If this be correct, Mr. McLean should not have much difficulty in disposing of the same at a good figure.—*Critic*.

Quebec.

Operations at the Asbestos mines have been steadily carried on since our last, and the output will exceed previous years. Nearly all the output is contracted for and prices remain firm. Prices on No. 1 range from \$75 to \$80 per ton at mines.

Reports of a highly satisfactory nature continued to reach us from British and Canadian Mica and Mining Company's mines near Buckingham. Three new veins have been opened since our last issue, and these are yielding an unlimited quantity of mica of perfect transparency. One great advantage in working these valuable mines is found in the fact that all labour is carried on within the solid walls formed by the rocks, so that work is prosecuted day or night, winter or summer, with about equal advantage. Nor is there any hindrance from rain or snow, nor yet from surface drainage. Winter and summer the mine is dry. Another great economy is found in the fact that there is no heavy hauling, two horses doing all the work necessary. Mr. Key, an American miner of great experience in mica mining in the United States, has been appointed superintendent of the mines. Mr. Von Rehn, the manager, reports that his office is kept unusually busy just now filling large fall orders for home and foreign consumers.

Mr. Edward Wright has just returned from a visit to his silver mine on the Temiscamingue. A rich vein of ore has been struck and 300 tons mined. Smelting works have been erected and will shortly be in operation.

Ontario.

The annual general meeting of the shareholders of the Austin Mining company (limited) will be held at the office of the company, Ottawa, on Tuesday afternoon, 27th instant.

The work at the Bristol Iron Mines for the past month is only preparatory to a large output, and so far the work is done with a small force, pending the finishing of two of the Taylor-Langdon calcining furnaces, which are expected to be completed in six weeks, but the work of mining is nevertheless most satisfactory, for about 2,000 tons have been taken out presenting a splendid lot of ore. At present, besides sinking the shaft, three drifts are being opened out down the shaft, at a distance from each other of about 16 or 20 feet, and all through a mass of solid ore on each side. The new air compressor does its work most efficiently. Mr. Anderson, an expert from W. J. Taylor's Ore Calcining & Smelting establishment, Chester, New Jersey, is at present superintending the erection of the two furnaces, which, when completed, will roast from 80 to 90 tons per day of ore, and at a cost of not over 50 cents per ton. Mr. Anderson is surprised at seeing the quantity of ore exposed, and when it is treated

in the furnaces he is erecting will leave it a very rich ore for Bessemer steel. The ore is very easily worked with drills, as it is soft and friable. Mr. Barlow, of the Geological Survey, has recently been doing work for his department about the vicinity of the mines, and Mr. Obalski, the Quebec Government Mining Engineer, has also paid the mine a visit and proposes returning again shortly. The Bristol Mining Company propose shipping about 10,000 tons during the coming winter to Prescott or Brockville, to be forwarded to market early in spring. From 5,000 to 6,000 tons of ore are now at the pit's mouth.

This company with a capital of \$200,000 has made application to Parliament for Letters Patent of Incorporation.

Port Arthur District.

Rich ore is being taken out of the Rabbit Mountain Mine at a depth of 270 feet.

Some very rich specimens have recently been taken from the Ottawa Mining Company's location. There are no less than three veins of ample dimensions showing both native and sulphide of silver. The superficial developments so far show numerous veins well situated for mining purposes.

At the Atic Lake Mines, the property of Mr. W. A. Allan, Ottawa, a well defined vein of ore is now clearly shewn. In No. 1 shaft, which has already been sunk to a depth of over 20 feet, an assay has given 511 ounces to the ton. No. 2 shaft, three-quarters of a mile from No. 1, shews a vein carrying silver ore and native silver. There is every inclination that this will turn out a very valuable property. Silver and iron prevail throughout the entire district.

The Corporation of Port Arthur has decided to exempt from taxation a sampling mill for testing ore to be erected shortly by capitalists interested in the district.

The total value of the products of the Beaver Mine for the past two and a half months, in smelting ore and concentrates from the mill, is \$93,000. This may be relied on as being authentic.

Mr. F. A. Keefer's mining office, is daily visited by large numbers of tourists from the United States and various parts of the Dominion. Here can be seen substantial evidences of the value of the mines and mineral locations of the country, and files of local papers and mining journals with articles of interest on the resources of the district.

During the past month the mines were visited by Dr. Selwyn, Director of the Geological Survey of Canada. At this time when so much attention is being directed to the vast mineral wealth of this neighbourhood, the opinion of so eminent authority cannot fail to be of much interest to our readers; we have, therefore, no hesitation in reproducing the following excerpt from a letter written by him to Mr. T. A. Keefer, of Port Arthur:—

"As you are aware I had visited this district on two previous occasions, the last being in the autumn of 1885, when I was at the Silver Mountain mine. At that time there was not much being done and the veins had not been opened sufficiently to afford any opportunity to ascertain their true character, and I hesitated then to

say more than that the vein matter looked exceedingly promising. Now, however, I have no hesitation in expressing my conviction that this region is traversed by a great series of true fissure veins, of most promising appearance and many of which will most certainly prove of immense and permanent value.

"The features of the veins are especially well illustrated in the workings of the Beaver, the Rabbit Mountain and the Porcupine mines; but there seems no reason whatever why the numerous parallel veins which occur under precisely similar conditions, but on which at present only small openings have been made, should not develop into mines as rich as those above named and now being successfully worked. The 'New Porcupine,' the 'Silver Creek,' the 'Elgin,' and the 'Little Pig' all present most promising indications, and there are doubtless many more yet to be discovered in the large area in the district as yet almost unexplored and covered with forest and deep soil. In any case sufficient is now known to warrant the assertion that this region presents all the natural conditions for the development of an immensely valuable and extensive mining industry awaiting only the application of well directed energy and enterprise in order to secure results exceeding perhaps the most sanguine anticipations.

"As regards the ores of the mines above named and now being worked, their richness is such that it does not require to be demonstrated by assays, but the recent critical examination of the Porcupine mine ore by Mr. Brady may be referred to as particularly satisfactory, because it conclusively shows that the silver is distributed in all parts of the vein. Mr. Brady, I understand, broke samples indiscriminately from seven different places covering the length of the vein, and these separately assayed gave from 6 ozs. to 600 ozs. to the ton, and an average of the whole of 155 ozs. per ton.

"The softness of the country rock—a flat bedded, black argillite—and the generally well defined walls of the veins, make the cost of extraction comparatively small, a feature the importance of which is only fully recognized when the 'dead ground' or 'pinches,' incidental to all mineral veins, have to be traversed."

The mineral exhibit sent from the Port Arthur District to the Toronto Exhibition included iron, lead, gold, silver, copper ores, sandstone and marble; and of these the quality has proved to be of an excellent character. In common with other Canadian iron ores, the Algoma is said to be better for the making of the finer classes of iron and for the manufacture of steel than those of the American mines. Some of the samples shown assayed 68 per cent. and were remarkably free from titanium. Among the copper ore exhibits was one from the Sudbury mines, which are said to be among the richest in the world. The lead ores from Mr. Duncan McEachern's location at Black Bay were exceedingly rich and carried \$20 in silver to the ton of melted ore. There were five nuggets of silver from the famous Beaver mine weighing 700 lbs., and assayed to value nearly \$2,000. One piece alone weighed 265 lbs., having a value of \$262.50. These, with other specimens from Rabbit Mountain and the Silver Mountain mines, made the largest and most valuable display of silver ore ever shown in Canada. The gold ore specimens from the Lake of the Woods country in the vicinity of Rat Portage, were said to carry a large per centage of silver. Specimens of brown sandstone and marble from Nipigon, near Port Arthur, were to be seen in the rough, dressed and polished states. The sandstone shows qualities of a high order under the most severe tests, and is claimed to be, for building purposes, superior to anything on the continent. It is to be found in seemingly inexhaustible quantities. The marble admits of a high polish, and one of the beds is said to be a mile and a-half long and thirty feet deep. The excellence of the exhibit was very much admired.

Manitoba and North-West Territories.

The property owned by the Saskatchewan Coal Mining & Transportation Company will be sold at Winnipeg by public auction on 27th

inst. It is situated at Stair Station on the line of the Canadian Pacific Railway, about eight miles west of Medicine Hat. The title to the land is under grant from the Crown direct to the company, and the land itself is sold subject to a mortgage for \$3,200, payable at any time before the 1st day of June, 1888, with interest at 7 per cent. half-yearly in the meantime. There is no incumbrance on the houses or other property. The Saskatchewan soft coal is well and favourably known in the Province of Manitoba and the North-West Territories, and a very large quantity has been taken from this mine since it was opened. The terms and conditions are 20 per cent. on the day of sale, and the balance within thirty days.

Mr. McLeod Stewart, Mayor of Ottawa and one of the proprietors of the Anthracite Mine at the Rockies, in a conversation with a representative of the REVIEW, stated that at present there were 150 men employed in the mines, and from 150 to 175 tons of coal were being turned out daily. Some delay had occurred in laying the iron rails into the different chambers of the mine, but as soon as this work was completed the company would be in a position to turn out up to 500 tons a day; in fact the capacity for producing would be almost unlimited and fully equal to any demand. No. 1 seam is 9 feet wide, 7 feet of which is solid coal. No. 2 seam, which is a six foot lead, is increasing both in width and quality of coal as the miners penetrate. Already it has been pursued 500 feet at an angle of 32 degrees. Forty-five car loads of coal are now at Port Moody awaiting shipment to San Francisco in boats. Mr. Stewart says the company will probably be able to sell on the American Pacific Coast at \$11 a ton, which is two or three dollars cheaper than American coal has been sold there for. The price has been known to be as high as \$20 a ton. As to what the people of San Francisco think of the coal, Mr. Stewart exhibited the following certificate of G. A. Luckhardt, one the best known experts along the coast: "Upon examination and special quantitative analysis of your coal marked 'Canadian Anthracite Coal Company,' from Anthracite, N.W.T., Canada, I find that the coal is what is termed a free burning Anthracite coal, averaging with Pennsylvania coal. It is a good steam coal, and excellent for house and domestic purposes, containing a little sulphur." Mr. Stewart said that while west the Hon. Thomas White had visited the mine and expressed the greatest surprise and satisfaction at the results being obtained. He had no conception the mines were so extensive, and the general outlook so good. Mr. Stewart further stated that an extensive boarding house had been erected at the mine, and that he had just shipped a large quantity of furniture from Winnipeg for fitting it up. Mr. Inglis, the former Steward of the Rideau Club, Ottawa, has been appointed manager of the boarding house. Engines and revolving screens have been ordered and will be soon in position. Mr. R. C. Luther, of Pottsville, Pa., is Consulting Engineer.

A contract has been closed with the C. P. R. company to deliver at Vancouver for the San Francisco market 1,800 tons of the Canada Anthracite Company's coal. This is regarded as the inaugural shipment to that city—others will follow in rapid succession. It is believed that a regular fleet of colliers will be established between Vancouver or Port Moody (for it is on the boards to make Port Moody the headquarters of the shipping trade) and San

Francisco and other coast cities and towns. A thorough test has been made of this coal at the request of the Government of the Dominion, and it has been found to equal many of the best and most popular brands of the Pennsylvania article. Special transportation rates have been agreed upon by both the railway and the owners of the mines at Banff.

British Columbia.

Work at the Island Mountain Mine, Barkerville, is progressing quickly. The framework for the mill has been completed at the mine, the ledge has improved greatly, and the outlook is reported cheering.

"We are pleased," writes the *Colonist*, "to learn from Big Bend that three contiguous mineral claims in that promising locality are to be thoroughly tested. The locators of these claims have entered into an agreement with some well-known capitalists by which these latter undertake to sink shafts, etc., at their sole cost for eighty days; if the result of this test should be satisfactory they will pay \$4,000 in cash and develop the mine, at their own charge, by mill and appliances; they will then be entitled to three-fifths of the property, with the option of buying the locators' remaining two-fifths for the sum of \$20,000 at any time before the 31st December, 1888. This appears to us to be an excellent arrangement and we trust it will result in the development of a highly remunerative claim."

The same authority has been informed of an extraordinary gold-bearing lode at Albert Canyon, a C.P.R. station on the Illecillewaet. The locator declares that it has a width of twelve hundred feet, and that he has had assays made giving \$15, \$16 and \$20 a ton. The pieces were in all probability picked; if the ledge will yield on an average anything like these results, the location, on account of its position on the C.P.R., will become of enormous value.

A correspondent who has lately visited the recent find of Semi-Anthracite coal in Kootenay District, referred to in another column, writes:—

"I found very good work has been done here and the results are agreeably surprising. On one seam they are in fifty-five feet, with a shaft sunk from the hanging to the foot wall, a distance of thirty-five feet. Of this there are thirty feet of solid coal without a flaw in it. Then comes a bed of five feet of coal and shale mixed. Another seam near the former has twelve feet of solid pure coal. All these seams are superposed, one above the other, at distances varying from a hundred to forty feet apart. They are all opened up, showing the hanging and foot wall. The coal appears to be much of the same quality throughout. It is of a bright black and shining appearance, hardly soils the fingers when touched and makes a brilliant clear fire, with a smoke more like wood than ordinary coal. Near the surface it is very brittle, but becomes harder further into the seam. No signs of sulphur can be detected. It is used here for the hardening of the picks and answers the purpose admirably. It lies between sandstone walls, and there are strata of clay and ironstone. These are very regular for miles around and look as though they had been ruled with lines. All now depends on the quality of the coal, there is no doubt about the quantity."

The *Colonist* understands that it is the intention of the East Wellington Coal Company to at once commence the sinking of a second shaft on their coal property at East Wellington. The second shaft will be sunk further up the valley than the present shaft, and nearer the South Wellington colliery. A line is being surveyed to connect the new shaft with the present line of railway.

The diamond drill of the Vancouver Coal Company, in charge of Mr. John Hamilton, is making very good progress. It is now down about 360 feet, and is still going down.

In the Big Bend district the placer mining on McCullough, French, Smith and Cairnes creeks had been seriously retarded by the unusually high water, but the outlook now is better than ever, and the resumption of work on a large scale in the French Creek Tunnel Company's claim, now controlled by Montreal, Toronto and New York capitalists, has done much to restore confidence on that creek. The tail-race was cleaned up last week and showed very satisfactory results. Referring again to the development of quartz ledges nothing can be done to good advantage until a good waggon road is built from the steamboat landing to the mouth of French creek, about

twenty-two miles, and a vessel put on the river.

On Wild Horse creek eighty-five Chinamen are at work. A Chinese company purchased the mining ditch for five or six thousand dollars from white men, and are now taking out \$10 per day to the man.

At Perry creek, twenty miles from Cranbrook, a company of enterprising men are endeavouring to master the obstacles to successful mining on that creek. The quicksands and slum have heretofore prevented bed-rock being reached, but it is thought that the present means adopted will overcome this.—*Colonist*.

The Perry Creek Gold Mining Company has been incorporated to work a highly auriferous bed in the vicinity of Perry Creek, Kootenay

District. The gravel of the shaft now being sunk contains everywhere coarse gold. A space of four feet square has yielded \$90 in coarse gold.

*A paper read before the American Institute of Mining Engineers, at Seranton, February, 1887.

†Some coke recently obtained from the inner and older veins, lying nearest to the Cascade mountains, has

a firmness and hardness equal to that of Connellsville. My authority for this is Mr. Williamson, of Seattle—an old and experienced foundryman, who has for many years used Connellsville coke, for smelting iron.

‡Taking the cordilleran axis for our guide, the dividing line passes at its greatest northing near Behring Straits, within 23 degrees of the pole.

Lidgerwood Manufacturing Company's Hoisting Engine.

We present on this page an engraving of the Double Cylinder Reversible Link Motion Double Friction Drum and Brake Hoisting Engine, manufactured by the Lidgerwood Manufacturing Company, whose works are at Brooklyn, N.Y., and Offices and Salesrooms at 96 Liberty Street, New York. This is but one of the many styles of hoisting engines, for mining purposes, manufactured by this company, and is specially recommended for use in connection with the tail rope system, double track inclines or double compartment shafts. Both drums are loose on the drum shafts and are entirely independent of each other in operation. They may be thrown in and out of gear with the engines in motion, either separately or together, or one drum may be lowering while the other is hoisting; or both drums may be thrown into gear and the engine used as a regular reversible engine, one load being hoisted while the empty cage is being lowered.

LIDGERWOOD MANUFACTURING CO'S IMPROVED HOISTING ENGINE.

The obvious advantage of this style of engine for the tail rope system is evident, for as one drum being thrown into gear winds up the main rope, the other drum being out of gear and loose on the shaft pays out the tail rope; while, by reversing the engine, the tail rope is wound up and the main rope paid out. This is done with the minimum of friction and wear on the engines. The same independence of drum action is also very desirable at times on inclines or in mine shafts, under either of which conditions the engines will work with perfect satisfaction. In general design the engine is solid and compact, and is intended for high speed and large hoisting duty. The patent friction drums are of large diameter and spirally grooved for wire rope. They are simple, durable and effective. These engines are fitted with powerful band brakes on each drum, which are applied preferably by hand wheel and screw, or by the ordinary foot lever, if so desired.

VALUABLE

Copper Mining Properties

— IN THE —

Eastern Townships

TOWNSHIP OF ASCOT.

- 1st. Clark Mine, Lot 11, R. 7 Ascot 187 acres
 2nd. Sherbrooke Mine, part Lots 12 and 13,
 R. 7 Township of Ascot 329 "
 3rd. Belvidere Mine, part Lots 9 and 10, R.
 9 and 10, R. 8 Ascot 292 "
 4th. Mining Rights in same vicinity on 250 "

All of the above properties lie within $1\frac{1}{2}$ miles of the Village of Lennoxville, at the junction of the Grand Trunk, Canadian Pacific and Passumpsic Railways, and have been developed to a considerable extent, and veins opened 6 to 20 feet in width, yielding 3 to 5 per cent. of copper, also silver, and 35 to 40 per cent. of sulphur. These mines are only $2\frac{1}{2}$ to 3 miles distant from the City of Sherbrooke, and evidently are of the same class of ores found at Copelton, only four miles distant, owned and worked by the Orford Copper and Sulphur Company, and by Messrs. G. H. Nichols & Co., of New York, which have proved so remunerative.

TOWNSHIP OF ORFORD.

- 5th. Carbuncle Hill Mine, Lots 2 and 3 R. 14, and 2, 3, 4 R. 15, 718 acres. Same class of ore as is found in the Ascot properties above described, but yielding a higher percentage of copper.

TOWNSHIP OF CLEVELAND.

- 6th. St. Francis Mine, $\frac{1}{4}$ Lot 25 R. 12, 50 acres, with dwelling houses, smith's shop, ore sheds and office, large winding and pumping steam engine, with boiler, winding and pumping gear, and about forty fathoms Cornish lifting pumps complete, railway tracks, ladders, etc., situated three miles from Grand Trunk Railway. A considerable amount of mining work has been done at this mine. A well defined vein richly charged with vitreous purple and yellow sulphurets of copper traverse the entire length of the property, five feet in thickness, yielding 8 to 40 per cent. metallic copper.

TOWNSHIP OF GARTHBY.

- 7th. Fifty-six lots of land, 2,938 acres. This property for the most part is unexplored, but copper is found on the greater part of the property. On one of the lots a vein about twenty feet in width has been found. Samples of the ore have yielded as much as 22 per cent. of copper, being also rich in sulphur. Other samples of pyrites from the same property, free from copper, have yielded as high as 48 per cent. of sulphur. The only drawback to this property is in its distance from the railway, it being about four miles from Garthby Station, Quebec Central Railway. A new line is chartered, however, which, when built, will run directly through the property.

TOWNSHIP OF ACTON.

- 8th. The Acton Mine, 100 acres, with engine, boiler, pumps and appliances. Within three years after this mine was first opened it produced nearly \$500,000 worth of copper. It is situated about half a mile distant from the stations of the Grand Trunk and South Eastern Railways.

- 9th. Brome Mine, part Lots 2 and 3 R. 4, 50 acres.

- 10th. Bolton Mine, two miles from Eastman Station, Waterloo & Magog Railway, 400 acres.

The above properties formerly belonged to the Canadian Copper and Sulphur Company, and were acquired by the present owner at sheriff's sale, giving an indisputable title thereto.

The whole or any portion of the property will be sold at reasonable prices.

Mining Regulations

TO GOVERN THE DISPOSAL OF

Mineral Lands other than Coal Lands,

1886.

THESE REGULATIONS shall be applicable to all Dominion Lands containing gold, silver, cinnabar, lead, tin, copper, petroleum, iron or other mineral deposits of economic value, with the exception of coal.

Any person may explore vacant Dominion Lands not appropriated or reserved by Government for other purposes, and may search therein either by surface or subterranean prospecting for mineral deposits, with a view to obtaining under the Regulations a mining location for the same but no mining location or mining claim shall be granted until the discovery of the vein, lode or deposit of mineral or metal within the limits of the location or claim.

QUARTZ MINING.

A location for mining, except for iron on veins, lodes or ledges of quartz or other rock in place, shall not exceed forty acres in area. Its length shall not be more than three times its breadth and its surface boundary shall be four straight lines, the opposite sides of which shall be parallel, except where prior locations would prevent, in which case it may be of such a shape as may be approved of by the Superintendent of Mining.

Any person having discovered a mineral deposit may obtain a mining location therefor, in the manner set forth in the Regulations which provides for the character of the survey and the marks necessary to designate the location on the ground.

When the location has been marked conformably to the requirements of the Regulations, the claimant shall within sixty days thereafter, file with the local agent in the Dominion Land Office for the district in which the location is situated, a declaration or oath setting forth the circumstances of his discovery, and describing, as nearly as may be, the locality and dimensions of the claim marked out by him as aforesaid; and shall, along with such declaration, pay to the said agent an entry fee of FIVE DOLLARS. The agent's receipt for such fee will be the claimant's authority to enter into possession of the location applied for.

At any time before the expiration of FIVE years from the date of his obtaining the agent's receipt it shall be open to the claimant to purchase the location on filing with the local agent proof that he has expended not less than FIVE HUNDRED DOLLARS in actual mining operations on the same; but the claimant is required, before the expiration of each of the five years, to prove that he has performed not less than ONE HUNDRED DOLLARS' worth of labor during the year in the actual development of his claim, and at the same time obtain a renewal of his location receipt, for which he is required to pay a fee of FIVE DOLLARS.

The price to be paid for a mining location shall be at the rate of FIVE DOLLARS PER ACRE, cash, and the sum of FIFTY DOLLARS extra for the survey of the same.

No more than one mining location shall be granted to any individual claimant upon the same lode or vein.

IRON.

The Minister of the Interior may grant a location for the mining of iron, not exceeding 160 acres in area which shall be bounded by north and south and east and west lines astronomically, and its breadth shall equal its length. Provided that should any person making an application purporting to be for the purpose of

mining iron thus obtain, whether in good faith or fraudulently, possession of a valuable mineral deposit other than iron, his right in such deposit shall be restricted to the area prescribed by the Regulations for other minerals, and the rest of the location shall revert to the Crown for such disposition as the Minister may direct.

The regulations also provide for the manner in which land may be acquired for milling purposes reduction works or other works incidental to mining operations.

Locations taken up prior to this date may, until the 1st of August, 1886, be re-marked and re-entered in conformity with the Regulations without payment of new fees in cases where no existing interests would thereby be prejudicially affected.

PLACER MINING.

The Regulations laid down in respect to quartz mining shall be applicable to placer mining as far as they relate to entries, entry fees, assignments, marking of localities, agents' receipts, and generally where they can be applied.

The nature and size of placer mining claims are provided for in the Regulations, including bar, dry, bench creek or hill diggings, and the RIGHTS AND DUTIES OF MINERS are fully set forth.

The Regulations apply also to

BED-ROCK FLUMES, DRAINAGE OF MINES AND DITCHES.

The GENERAL PROVISIONS of the Regulations include the interpretation of expressions used therein; how disputes shall be heard and adjudicated upon; under what circumstances miners shall be entitled to absent themselves from their locations or diggings, etc., etc.

THE SCHEDULE OF MINING REGULATIONS

Contains the forms to be observed in the drawing up of all documents such as:— "Application and affidavit of discoverer of quartz mine." "Receipt for fee paid by applicant for mining location." "Receipt for fee on extension of time for purchase of a mining location." "Patent of a mining location." "Certificate of the assignment of a mining location." "Application for grant for placer mining and affidavit of applicant." "Grant for placer mining." "Certificate of the assignment of a placer mining claim." "Grant to a bed rock flume company." "Grant for drainage." "Grant of right to divert water and construct ditches."

Since the publication, in 1884, of the Mining Regulations to govern the disposal of Dominion Mineral Lands the same have been carefully and thoroughly revised with a view to ensure ample protection to the public interests, and at the same time to encourage the prospector and miner in order that the mineral resources may be made valuable by development.

COPIES OF THE REGULATIONS MAY BE OBTAINED UPON APPLICATION TO THE DEPARTMENT OF THE INTERIOR

Department of Inland Revenue.—An Act respecting Agricultural Fertilizers.

The public is hereby notified that the provisions of the Act respecting AGRICULTURAL FERTILIZERS came into force on the 1st of January, 1886 and that all Fertilizers sold thereafter require to be sold subject to the conditions and restrictions therein contained—the main features of which are as follows:

The expression "fertilizer" means and includes all fertilizers which are sold at more than TEN DOLLARS per ton, and which contains ammonia, or its equivalent of nitrogen, or phosphoric acid.

Every manufacturer or importer of fertilizers for sale, shall, in the course of the month of January in each year, and before offering the same fertilizer for sale, transmit to the Minister of Inland Revenue, carriage paid, a sealed glass jar, containing at least two pounds of the fertilizer manufactured or imported by him, with the certificate of analysis of the same, together with an affidavit setting forth that each jar contains a fair average sample of the fertilizer manufactured or imported by him; and such sample shall be preserved by the Minister of Inland Revenue for the purpose of comparison with any sample of fertilizer which is obtained in the course of the twelve months then next ensuing from such manufacturer or importer, and which is transmitted to the chief analyst for analysis.

If the fertilizer is put up in packages, every such package intended for sale or distribution within Canada shall have the manufacturer's certificate of analysis placed upon or securely attached to each package by the manufacturer; if the fertilizer is in bags, it shall be distinctly stamped or printed upon each bag; if it is in barrels, it shall be either branded, stamped or printed upon the head of each barrel or distinctly printed upon good paper and securely pasted upon the head of each barrel, or upon a tag securely attached to the head of each barrel; if it is in bulk, the manufacturer's certificate shall be produced and a copy given to each purchaser.

No fertilizer shall be sold or offered or exposed for sale unless a certificate of

analysis and sample of the same shall have been transmitted to the Minister of Inland Revenue and the provisions of the foregoing sub-section have been complied with.

Every person who sells or offers or exposes for sale any fertilizer, in respect of which the provisions of this Act have not been complied with—or who permits a certificate of analysis to be attached to any package, bag or barrel of such fertilizer, or to be produced to the inspector, to accompany the bill of inspection of such inspector, stating that the fertilizer contains a larger percentage of the constituents mentioned in sub-section No. 11 of the Act than is contained therein—or who sells, offers or exposes for sale any fertilizer purporting to have been inspected, and which does not contain the percentage of constituents mentioned in the next preceding section—or who sells or offers or exposes for sale any fertilizer which does not contain the percentage of constituents mentioned in the manufacturer's certificate accompanying the same, shall be liable in each case to a penalty not exceeding fifty dollars for the first offence, and for each subsequent offence to a penalty not exceeding one hundred dollars. Provided always that deficiency of one per centum of the ammonia, or its equivalent of nitrogen, or of the phosphoric acid, claimed to be contained, shall not be considered as evidence of fraudulent intent.

The Act passed in the forty-seventh year of Her Majesty's reign, chaptered thirty-seven and entitled, "An Act to prevent fraud in the manufacture and sale of agricultural fertilizers," is by this Act repealed, except in regard to any offence committed against it or any prosecution or other act commenced and not concluded or completed, and any payment of money due in respect of any provision thereof.

A copy of the Act may be obtained upon application to the Department of Inland Revenue.

E. MIALL,
Commissioner.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Post Office at Gananoque, Ont.," will be received at this office until Thursday, the 3rd November, for the several works required in the erection of Post Office at Gananoque, Ont.

Specifications can be seen at the Department of Public Works, Ottawa, and at the office of the Collector of Customs, Gananoque, on and after Tuesday, 18th October, and tenders will not be considered unless made on form supplied and signed with actual signatures of tenderers.

An accepted bank cheque payable to the order of the Minister of Public Works, equal to five per cent. of amount of tender, must accompany each tender. This cheque will be forfeited if the party decline the contract or fail to complete the work contracted for, and will be returned in case of non-acceptance of tender.

The Department does not bind itself to accept the lowest or any tender.

By order,
A. GOBEIL,
Secretary.

Department of Public Works,
Ottawa, 13th October, 1887. }

NOTICE RESPECTING PASSPORTS.

PERSONS requiring passports from the Canadian Government should make application to this Department for the same, such application to be accompanied by the sum of four dollars, in payment of the official fee upon passports as fixed by the Governor-in-Council.

G. POWELL,
Under Secretary of State.
OTTAWA, 19th Feb., 1886.

Notice to Contractors.

SEALED TENDERS addressed to the undersigned and endorsed "Tender for Roofing," will be received at this office until Monday, the 10th October, for the several works required in connection with Copper Roofing to Main Tower of Western Departmental Building and Lead Roofing in rear of Commons and Senate Chambers, Ottawa.

Specifications can be seen at the Department of Public Works, Ottawa, on and after Monday, 3rd October, and tenders will not be considered, unless made on form supplied and signed with actual signatures of tenderers.

An accepted bank cheque, payable to the order of the Honorable the Minister of Public Works, equal to five per cent. of the amount of the tender, must accompany each tender. This cheque will be forfeited if the party decline the contract, or fail to complete the work contracted for, and will be returned in case of non-acceptance of tender.

The Department will not be bound to accept the lowest or any tender.

By order,
A. GOBEIL,
Secretary.
Department of Public Works,
Ottawa, Sept. 20th, 1887.

CONDUCTED BY B. T. A. BELL.

The CANADIAN MINING REVIEW, is devoted to the opening up of the mineral wealth of the Dominion, and its publishers will be thankful for any encouragement they may receive at the hands of those who are interested in its speedy development.

Visitors from the mining districts, as well as others interested in Canadian Mineral Lands, are cordially invited to call at our office.

Mining news and reports of new discoveries of mineral deposits are solicited.

All matter for publication in the REVIEW should be received at the office not later than the 10th of the month.

Address all correspondence, &c., to the Manager of the CANADIAN MINING REVIEW, Ottawa.

To Subscribers.

Recognising the daily increasing importance of the mining district of Port Arthur, the management have secured the services of a distinguished mining engineer, who will, from this issue, furnish our readers with authentic information as to the progress and development of these mines. Thoroughly competent correspondents have also been secured for other districts hitherto but imperfectly covered. THE REVIEW having been permanently enlarged to sixteen pages, subscribers will please note that the subscription price for 1888 has been increased to \$1.50. The management would again request that any irregularity in the delivery of subscribers' copies be at once notified to the office for correction.

Gold Assays.

The Village of Buckingham has been greatly exercised by reported discoveries of gold in the neighbourhood. A California miner who has been prospecting on a lot on the west side of the Lievre River, in the township of Buckingham, has exposed a vein of quartz about seven feet wide, and a sample said to have been taken from it has given an assay showing 42 ounces to the ton, equal to \$750. A specimen has been shown yielding a flake of gold as large as a five cent piece. Accurate samples have been taken from the vein by a prominent mine manager and submitted for assay, and the result is awaited with interest.

There appears to be considerable uncertainty about gold assays. Not only are the samples often the richest specimens obtainable, but the analysts' results are variable. Samples of quartz from the Mattawa district reported to have

given a rich percentage of ore have been re-assayed and have been pronounced to contain little or no traces of gold. Others taken from the properties of the Anglo-Canadian Phosphate Company, North Burgess, have assayed \$22, \$11, and \$5 to the ton, but subsequent trials, like those from Mattawa, gave no gold whatever. Specimens taken from a mine near Kingston yielded \$67, \$18, and nothing, in three trials, while a ten ton lot of the same ore crushed and treated at reduction works gave but \$6.00 per ton. Numerous other instances might be cited. It is evident that both samplers and chemists need both caution and instruction, and that too much credence should not be given to the first reports of gold bonanzas.

The facts of this latest discovery having been reported to one of the most eminent geologists in the United States, he remarks that the rocks of this region warrant the expectation of gold finds. He would expect it to occur chiefly in the slaty rocks or schists having small veins of quartz penetrating them. He recommends the search for gold to be made first in the streams and brooks, wherever there is running water. Two men with a crowbar and pan can prosecute the search effectively. The large stones should be pried out of the water bed, and the gravel and dirt in the bottom should be carefully washed in the pan. The result will show whether the surrounding rocks contain any gold, and, if so, search can then be made for its source.

The Calabogie Disaster.

The accident at the Calabogie Iron Mine, some particulars of which are given in another portion of THE REVIEW, is another of those disasters which urge the necessity of experienced and careful management in our mines, as well as the enforcement by legislation of a thorough system of mine inspection. We have again and again advocated that there should be some law enacted which would compel owners and superintendents to take every necessary precaution for the protection of the lives of their employees. In the absence of information as to the cause of this sad affair we refrain from further comment.

The Yukon Mines.

A few days before Dr. Dawson left on his Alaskan Survey we took occasion to refer to some very unfavourable reports then prevalent as to the richness of the minerals of this far off land. These stated that the mining, which is almost entirely placer, had been grossly exaggerated, and that food and provisions of all kind were so scarce that many of the miners had been glad to get out of the country alive. This is now corroborated by a letter to the *Colonist* signed by seven Yukon miners, who state that the reports of the country have been very highly coloured, and that the results to be gained by the venturesome spirits who have braved the perils of that long and arduous

journey to and from the mines are totally inadequate. On Dr. Dawson's return, in the course of next month, we hope to be able to furnish our readers with information as to the true state of affairs. The paragraph in another place headed "Mining in Alaska," is excerpted from a long article in the *Sitka Free Press*.

The Phosphate Market in the United States.

The increasing use of mineral manures in the Northern States warrants the belief that in the near future an extensive market for Canadian phosphate will be found in that region. Orders from Chicago and Buffalo have been received this season and many requests for samples have come from other places. As freights can be had by the returning grain vessels from Kingston to Chicago for \$1 per ton and it costs \$4.50 to take the Carolina phosphates there by rail, it is clear that the Canadian article will have a virtual monopoly of the Lake Shore region, especially as it contains about 25 per cent. more of phosphate of lime than the Carolina phosphate.

One difficulty in the extension of the use of Canadian phosphate in the United States is the inability of manufacturers to treat it in all cases with satisfaction. When it was first introduced into the United Kingdom it was found that the fluoric acid contained in it affected the workman's throat injuriously and occasioned a stench that was offensive to the neighborhood. For these reasons its use was discontinued, until after some years of experiments, these objections were obviated, and now it is used extensively both in the United Kingdom and on the continent without complaint. One of the largest manufacturers in the United States says he is deterred from its use from fear of the complaint of his workmen. But as these difficulties have been overcome abroad, there seems no reason to suppose that they cannot be met successfully on this continent. If any manufacturer desires to know better how to treat this article we are able to place them in communication with one of the most experienced makers of superphosphate in England who would cheerfully give them information.

An Odious Comparison.

Having in recent issues looked into the question of our Geological Surveys and their relation to the Provincial Revenue, we now come to the consideration of the benefits actually derived by the several provinces of the Dominion from this indispensable branch of Government work.

Nova Scotia and British Columbia reserve the minerals for the use of the mining section of the population, and publish annual reports of the industry, and have each a Minister of Mines as a necessary result of so wise a course; while in Ontario and Quebec, the mining laws are such that only a very small revenue is derived from this source. In Ontario, wholly from sales, while in Quebec sales and royalty on

gold, to a small extent, which is more than balanced by expenditure in police! From the accounts of the provinces named, from 1880 to 1886, the following is given as the revenue and expenditure under this branch of service:

Nova Scotia.

Year.	Revenue.	Expenses.
1880.....	\$ 49,294.11	\$ 6,000.00
1881.....	70,602.82	6,638.79
1882.....	101,768.28	10,161.90
1883.....	108,977.84	10,785.36
1884.....	122,024.20	10,000.00
1885.....	100,692.50	10,720.75
1886.....	119,367.03	10,538.05
Total.....	\$672,726.78	\$64,844.85

British Columbia.

Year.	Revenue.	Expenses of Provincial Secretary and Minister of Mines.
1880.....	\$18,906.50
1881.....	43,813.60
1882.....	46,098.70
1883.....	38,197.75
1884.....	32,652.50
1885.....	37,642.60
1886.....	70,500.00	\$13,390.00
Total.....	\$287,811.65	\$13,390.00

Ontario.

Revenue from Sale of Mining Lands in Unsurveyed Territory.

1880.....	\$ 938.98
1881.....	120.00
1882.....	1,820.00
1883.....	12,073.00
1884.....	12,213.00
1885.....	3,551.00
1886.....	9,023.00
Total.....	\$39,738.98

Quebec.

Year.	Sales, Woods and Forests.	Revenue from Gold Royalty.	Expenses of Collecting Royalty and Police.
1881.....		\$ 893.00	\$ 432.30
	Mineral Lands fines	145.30	
1882.....	7,905.85	2,908.00	3,133.57
1883.....	15,907.48	1,620.00	4,037.30
1884.....	27,012.15	1,000.02	4,926.02
	Mineral Land Sales		
1885.....	1,966.60	525.00	4,078.53
Total..	\$52,792.08	\$7,091.32	\$16,607.72

Recapitulation.

	Average Annual Revenue from	Average Annual Expenditure.
Nova Scotia—Rent or Royalty.....	\$96,103.82	\$9,263.55
British Columbia—Rent or Royalty.....	41,114.52	say 10,000.00
Ontario—sales.....	5,676.99	no figures given
Quebec—sales.....	13,198.02	3,321.54
Average royalty.....	\$1,418.26	

It is, therefore, apparent that Nova Scotia has an average annual income from royalty or rent of minerals equal to \$96,103, collected at a cost of \$9,263, and British Columbia also receives yearly from rent or royalty \$41,114, at a cost of say \$10,000, while in Ontario and Quebec the mining interests are so mismanaged that little or no revenue is derived from rent or royalty, but the future welfare of the mining industry is sold unconditionally to speculators and farmers by the Local Legislators of the last mentioned provinces, "having no care for the future and letting the future of the mineral wealth of these provinces take care of itself."

The Mowat administration has a supreme contempt for "Old Tomorrow," and does not lay up treasure in the development of the mines and minerals of the country, although the Hon. Mr. Pardee writes an annual report in glowing colours of the great mineral wealth of the province, but sells as mining lands for a small sum to such of his unbelieving friends as do lay up treasure in the unconditional ownership of the miner's portion. What must our admiration be of his glowing reports which describe unbounded mineral wealth while no means are taken to make it a source of provincial revenue or advancement, but as is proved by the figures and doings of that department, this is placed in the hands of those who are party friends or agents, and held in reserve for these party agents even when applied for by prospectors and explorers? Hence the necessity for the location of a mineral discovery on the ground by the discoverer and then in the Land Office, and thereby avoiding the present legalized system of abuse—we had almost used a stronger term. The Hon. Mr. Pardee does not even condescend to state how much is actually received from mining land sales, except those in unsurveyed territory. Why is he ashamed to do this? Does he dread the exposure of the names and thousands of acres of mineral lands held by political friends possessing the special qualification of calling themselves "Reformers," but whose principal "reform" is to appropriate legally under the present unjust system of granting mining lands, the hard earned labour of such unfortunate explorers or prospectors as fall into the trap laid for the innocent and unsuspecting. Nor yet is the hon. gentleman content with writing a glowing mining report, but he has special agents. It would be interesting to know what the qualifications and remunerations are of these employees of the Ontario Crown Lands Office. Do they consist in *slaughtering* the interests of prospectors and miners who desire to earn an honest living? or of *sticking* and *bleeding* capital due to early trade experience which shows a strong hereditary tendency to develop, or *butchering* a good mining prospect? Or *fleeing* a good mining company which has to pay for errors and blunders due to ignorance or inexperience in the business? Does the Mowat Government do such an agent justice if they merely print a very self-interested report, and can such an expenditure of personal advertising be considered a wise expenditure of the people's money? We regret, exceedingly, the state of the Hon. Mr. Pardee's health, and trust that for his own sake and the good of the mining interests of the province he will retire into the sweet shades of private seclusion where he will better aid by his absence from office the interests of the mining community, and we sincerely trust that his successor will not encourage the present system of locking up large sections of our mining lands for party friends and special agents or reporters on mining matters.

In the Province of Quebec the condition of the mining laws is equally unsatisfactory with that of Ontario, and it is to be hoped that the present Government will consider this matter at least from a point of self-preservation if not from the higher motive of the greatest good for the largest section of the community, and not in the special interests of a few partisans as is the case in Ontario. In the report for 1880-81 it is stated "The Quebec General Mining Act was sanctioned on the 24th July, 1880, and consequently was not in force during the whole of the period embraced by the present report. However, during the short space of time which has elapsed, it has already begun to produce the two-fold effect which the Legislature had in view in adopting it namely, increasing the revenue and more especially developing the mining resources of the country. In proof of this statement I have but to refer to the figures given above and to the statement annexed hereto."

In 1885, however, the mineral land sales only amounted to \$1,966.60, so that the speculation in mineral lots was not even benefitted by the Quebec General Mining Act, as was expected. The craze for speculating in phosphate lands during 1882, 1883 and 1884 having collapsed in 1885, and in the report for that year it is stated that "a sum of \$525 for mining licenses was levied on the parties engaged in mining. The corps of police employed to collect these fees and maintain order in the Chaudiere mining division cost the province \$4,078 53!" When such is the state of affairs in Ontario and Quebec, is it not time that the example of the sister provinces of Nova Scotia and British Columbia was introduced? Mining statistics we hold to be within the supervision of the respective provinces, and is only a little closer related to geological work than is the agricultural industry, and if so why not open experimental mines for the development of the mining industry in new or unproved districts with free or convict labour?

Ground Phosphate.

A conviction of the utility of the application of crude phosphate to the soil is steadily gaining way. Experiments with Canadian phosphate at Newport during the past season have shown a marked effect upon grape vines in hot houses, and its effect upon garden plants has been established beyond dispute. Many small manufacturers are glad to get the ore in the pulverized state for treatment with acid, and there seems to be much encouragement for the erection of grinding mills.

The mills at the Basin du Lievre have been kept busily at work and a shipment of 300 tons of the ground ore has been made to Hull, England. In the future it is probable that the high grade ore will be selected for shipment abroad in the crude state and all the low grade ore will be ground and raised in quality by

freeing it from mica and other impurities. The market for this will be found in the United States and Canada. More active exertions ought to be made by the Department of Agriculture and the Geological Survey to impress upon farmers the desirability of using phosphatic manures.

It is thought that Kingston affords a favorable site for the erection of phosphate grinding mills. Coal can be had cheaply there and the phosphate can be brought to it at low rates by the Rideau Canal and exported as ballast in the lake schooners. It is likely that this enterprise will be undertaken before long and will have a marked effect in stimulating the phosphate industry.

On Some Canadian Minerals.

By B. J. Harrington, B.A., Ph.D., F.G.S.*

I.—SODALITE.

The mineral sodalite, though not the only silicate containing chlorine, is interesting on account of the considerable proportion of that element which it holds. Its occurrence in Canada was first noticed by Dr. Hunt, who, many years ago, detected it in small quantity in the nepheline-syenite (*granitoid trachyte* of Hunt) of Brome Mountain. Subsequently it was found by the writer in some of the nepheline-syenites of Montreal and Belœil, and more recently it has been discovered by Dr. G. M. Dawson, on the Ice River, a branch of the Beaver Foot River, near Kicking Horse Pass, in the Rocky Mountains.

The mineral from Montreal was described by the writer in 1875, and lately that from the Rocky Mountains has been examined. In both cases the results of analysis agree closely with the formula $3\text{Na}_2\text{Al}_2\text{Si}_2\text{O}_8 + 2\text{NaCl}$, and are as follows:—

CONSTITUENTS.	Montreal.	Ice River.	Formula.
Silica.....	37.52	37.50	37.1
Alumina.....	31.38	31.82	31.7
Ferric oxide.....	tr.	0.01
Lime.....	0.35
Magnesia.....	tr.
Soda.....	19.12	19.34	19.2
Potash.....	0.78	0.27
Sodium.....	4.48	4.61	4.7
Chlorine.....	6.91	7.12	7.3
Total.....	100.54	100.67	100.0
Specific Gravity.	2.220	2.293

Both varieties are of a fine blue colour, and that from the Rocky Mountains might be employed for the purposes of jewelry. A very beautiful polished specimen of it may be seen in the museum of the Geological Survey at Ottawa. The hardness in each case is 5.5.

The rocks in which the sodalite occur require further study. One of them is a nepheline-syenite, closely resembling, both macroscopically and microscopically, some of those found near Montreal, whilst another, in which the sodalite appears to be most abundant, is a grey gneiss-like rock containing a great deal of quartz, and possibly fragmental.

II.—HURONITE.

The name "Huronite" was long ago given by Dr. Thomson, of Glasgow, to a mineral which was found in a boulder of diabase on Drummond Island, in Lake Huron, and which was sent to him by the late Dr. Holmes, of Montreal. Thomson regarded it as a new species and

published a description and analysis of it in his "Mineralogy" in 1836.

Dana, in his "Mineralogy," speaks of it as "an impure anorthite-like feldspar," but also includes it with fahnlunite, on the authority of Hunt. Its true affinities are evidently with the feldspars, and it may be looked upon as an impure or altered form of anorthite. One of the original specimens from Drummond Island is in the Holmes collection at McGill College, and an examination of this shows that Thomson's description is in several respects incorrect. The hardness, for example, is about $5\frac{1}{2}$ instead of $3\frac{1}{4}$, as stated by Thomson. Instead of being infusible, it is distinctly fusible (F about 5), while it contains alkalies, the presence of which is entirely ignored by Thomson.

As we have seen, the mineral from Drummond Island was found in boulders, and the origin of these was not known. About two years ago, however, an exactly similar material was discovered *in situ* by Dr. Girdwood near Sudbury, Ontario, where it occurs in rounded or somewhat angular masses in a dark green dyke of diabase, possibly the source of the boulders on Drummond Island. The Sudbury mineral, like that from Drummond Island, is of a light yellowish green colour, shows somewhat indistinct cleavage, and in places, faint striae, which are probably due to multiple twinning. It is translucent on the edges, and has a rather waxy lustre. The hardness is $5\frac{1}{2}$, or a little over, fusibility about 5, and specific gravity 2.814. Under the microscope, thin sections give evidence of considerable alteration, but with polarized light, the banding due to twinning can be seen in places. An analysis made by Mr. Nevil N. Evans, chemical assistant in the laboratory of McGill College, is given under I., while Thomson's is given under II.—

CONSTITUENTS.	I.	II.
Silica.....	47.07	45.80
Alumina.....	32.49	33.92
Ferric Oxide.....	0.97	FeO 4.32
Lime.....	13.30	8.04
Magnesia.....	0.22	1.72
Potash.....	2.88
Soda.....	2.03
Loss on ignition.....	2.72	4.16
Total.....	101.68	97.96

Specific gravity..... 2.814 2.8625

The rock in both cases is a true diabase, although that examined by Thompson was supposed by him to be hornblende. In each case, the microscope shows the presence of augite, a green chloritic mineral, titanite iron ore, and a more or less decomposed plagioclase, the altered portions of which are probably identical with the so-called "huronite."

III.—APATITE.

Though much has been written with regard to Canadian apatite, little attention seems to have been paid to its crystalline form. In so far as the writer's observation goes, the crystals of most common occurrence consist simply of a combination of the hexagonal prism and pyramid (∞ P.P.) A large proportion of the crystals from Renfrew County, however,

exhibit the end-face in combination with the above forms, and resemble the well-known crystals from Snarum in Norway. More rarely,

the Renfrew crystals have their vertical edges truncated by the prism of the second order, ∞ P2,† while in a few cases, which have recently come under the writer's notice, a pyramid of the second order (2P2) is also present, the full combination in this case being, as shown in the accompanying drawing, ∞ P. P. 0P. 2P2. ∞ P2.

Mining Developments on the Northwestern Pacific Coast, and their Wider Bearing.

By Amos Bowman, M.E.

Continued from September number.

Gold-Bearing Rocks.—The gold region of Cariboo, one of earliest notable placer-fields discovered, and one of the most profitably worked after California, possesses many characteristics in common with California and Colorado, a few of which I will mention. Though it was the placer-deposits which first attracted attention, they were due to underlying quartz veins and to the country-rock, which was slate. The miners of 1858-61 scoured the plateau for "slate countries;" and they were rather fastidious about the kind of slate; it must be like that of California. I have frequently found the miners most excellent geologists within the limits of their knowledge. Now those slates containing the auriferous deposits were deep-water sediments, antedating the coal, and experienced squeezing, and then baking, and are at last broken, or cracked in places, while the coal-making was still going on. In Cariboo, they were underlain by a limestone formation of Palæozoic age, containing fossils, and are much older in date of original deposit than those of California, which have been determined by its State geologist to be Triassic. In California, however, the fossiliferous rocks were very limited in area, and apparently lying in narrow belts, which may have been folded along with some non-fossiliferous Carboniferous or older rocks of the same slaty structure, such as are known to exist on the flanks of the Sierra; so that the evidences of their Palæozoic age, in part, may yet be forthcoming.

But the crumpling, and the quartz-forming, or filling-in process, was simultaneous with that in California. We know this because we have found in Cariboo, Cretaceous rocks containing fossils of the Shasta group, which tell the story of the uplift, as it does in California.

What there may have been in this deep-water sediment and its underlying (deeper water?) limestone deposits, to give origin to a great abundance of auriferous pyrites, with accompanying free gold, would be hard to say. But we get a little light when we study it in connection with other things. The uplift generated older volcanic outflows of Neocomian age, along with which there must have been a great deal of solfataric action. In British Columbia the older volcanic traps are bedded, and cover considerable areas, while in the gold region of California I have seen them only in the form of dykes.

Enrichment and its Consequences.—Beside the solfataric action, the proximity of the slates to crystalline rocks—commonly best seen in the flanges of the plateau—and time, may have had a good deal to do with the enrichment of the slates. Whatever may account for their enrichment, beyond the causes mentioned, these deep-water sediments lying along the great plateau-chain in America, Asia and Africa, constitute a study in physical geology as well as in gold mining, worthy of the attention of

the best observers. Since the conditions of its wealth in precious metals appear to be similar throughout the statesman is no less interested, for where the precious metals are found in quantity, judging the future by the past, there the prospector, the capitalist and the immigrant will *some day* congregate in mass.

Northern Conditions.—What I have just said, having a general bearing, leads me back to my particular field of Cariboo, in the same connection. Theories have been constructed to account for a supposed inferiority of mineral wealth along the plateau in northern latitudes. Some have imagined that volcanic action was lacking in the north, or that when we get far enough north, the colder climatic conditions might have hindered the favourable chemical action under ground. Others have simply enunciated the theory, as based upon fact, that the moment we cross the boundary line into Canada the happy things of nature no longer happen.

But theories are unnecessary, because the supposed facts are not facts. Cariboo has yielded \$30,000,000, chiefly from a few miles of placer-diggings on two creeks, Lightning and Williams creeks. Omineca and Cassiar, in latitude 55° to 57°, have told their story in gold-dust; and many million dollars have been extracted where the working season is only two months in the year; where the auriferous gravel has to be thawed with fires out of an ice conglomerate in which it has been bedded since the Glacial period. Little by little the explorers have continued following the plateau northward, until at the present time they are prospering under the Arctic circle. There is a flourishing placer-mining camp on Stewart River at the headwaters of the Yukon.

PLACER DEPOSITS.—I have cited these localities in evidence of mineral wealth in the rock. I will now direct attention to the placer-deposits, which are as much more interesting to us, in most respects, as they are nearer to us in time of formation.

Three circumstances have to combine favourably, to make a good placer-mining region: First, the veins must carry free gold along with the baser metals; secondly, the conditions of natural concentration in streams must have operated upon them; and thirdly, after such operation, the product must be accessible to the miner. Either of the last two conditions wanting, though we walked over untold millions, we could not realize it through placer-mining. In California all three of these purely geological considerations happened to be superb. In British Columbia they are not exactly identical, nor are they the same in different parts.

Physiographical Comparisons.—The position of Cariboo in relation to the cordilleran aggregate corresponds with the higher portion of the drainage-basins of the Columbia, the Snake, and the Colorado rivers, within the western flange, while California is outside. In the raising of the plateau accordingly, the two areas were subjected to different degrees of movement, different influences in the matter of successive rest and re-elevation or depression, and possibly even to opposite movements. Certain leading facts, however, are alike in both regions. The streams of the northern plateau experienced the same period of erosion in the early Tertiary, as those of the south, including California outside of the western flange. Again, the Miocene brown coals of the northern plateau found the necessary conditions of growth and deposit at the close of the eroding period contemporaneously with the brown coals of Ione and Lincoln

in California. Again, in the Miocene and Pliocene periods there followed a silting-up of the old eroded rivers in the northern interior, just as we have found them in California. And lastly, the Tertiary was concluded by volcanic outflows in both places.

Silted Channels—The Cause.—The most important feature of a placer-mining region, which I have barely hinted at as among the favourable conditions, is this filling of the old eroded canons as a means of arresting the gold. It was accomplished pretty much at the same time, and in the same way, everywhere along the great cordilleran region, so far as I have had the opportunity to observe.

The silting-up was due to an alteration in the transporting power of running water, involving a different combination of its two factors of volume and grade. Professor Whitney attributes all to a change in volume, and Professor Le Conte all to a change in grade. Without discussing the amounts of depression and re-elevation experienced by those two different parts of the cordilleran region during the placer filling, and the present eroding period, which is a very interesting one, I will simply bear testimony to two facts bearing on the subject, viz:

1. At the outlets of the auriferous mountain streams of Cariboo district, we see them debouching upon the plains of the interior plateau, and underneath the surface in disconnected basins, a Miocene brown coal. Overlying the brown coal are seen bluffs of still-water bedded gravels, blending into the stream-bedded gravels, of the gold region. The gravels of the silting-period were dumped into standing water, which ran horizontally along the base of the mountains, not less than 100 miles, and vertically not less than 600 feet above the general level.

2. At the out-lets of the auriferous streams of the Sierra Nevada they are seen debouching upon the plains of the Sacramento, holding under the surface the brown coals already mentioned; while at Table Mountain, in Butte County, they are seen to have dumped their silts and gravels into standing water, at not less than 600 feet above the present sea level.

There was thus, at least, a change of grade, as one of the factors of the transporting power of water. To this change of grade, if not to an absolute uplift, I would especially direct the attention of experts, as an important consideration, in looking up and down the cordillera at the auriferous deposits which may call for their examination.

The Modern Streams—A Divergence.—I have now an interesting divergence to note, in the physical history of the rivers of the northern interior plateau, from the conditions obtaining in California. It is true, the resemblance of conditions continues to hold further, in the fact that the lower Sacramento River runs entirely in silt, as also does the lower Fraser. So does the Fraser above the bed-rock canon, where it passes through the coast or Cascade Mountains. When we reached the headwaters of the Fraser, on which Cariboo is situated, the gold-bearing stream-beds are seen to have been filled like those in California; the waters at the *debouchure* have also subsided, and the modern streams have cut fresh canons, which are, for the most part, identical with the old, as they are in California. But the new erosions have not gone down to the bottom of the older canons, as they have in California. From 50 to 150 feet of the richest auriferous deposit is found underneath the stream-beds. All the rich placers of Cariboo have been mined by underground drifting, with all the difficulties of water and "slum" to contend with overhead. In

California, on the contrary, the modern streams have cut down at mid-slope a thousand feet deeper than the Tertiary streams preceding them had done.

All the difficulties in the way of the placer-miner are accordingly multiplied, on the northern plateau at least; and while I am not prepared to say, of my own knowledge, how it is in other portions of the plateau, I think it may be found the case generally within the eastern and western rims.

An Improvement.

Toronto, 30th Sept., 1887.

The Editor

THE CANADIAN MINING REVIEW:

SIR,—May I suggest that if your paper was *paged continuously*, as periodicals generally are, so that they may be bound and *indexed* for reference, it would be much more useful, to us at least. When we first subscribed for the REVIEW, I ordered the back numbers in order to have the full series bound (as I thought it would constitute a good history of mining in this province), and I was much disappointed to find that each number was paged separately. I have kept all the back numbers still, hoping that you would soon adopt the paging I have indicated.

Please excuse this suggestion if it does not meet your views.

SUBSCRIBER.

[The improvement suggested by our Toronto Subscriber is one which has been kept in view since the management of the REVIEW came into our hands. The change will be made commencing January issue, 1888.—*Edit.*]

Theory and Practice.

Brandon, October 4th, 1887.

The Editor

THE CANADIAN MINING REVIEW:

SIR,—

The theoretical geologist is he who studies the nature of geological phenomena in the laboratory and constructs doubtful solutions of the order of rock formations according to known chemical formula with an exactness due to the precision with which chemical reactions take place. The correspondent to a mining journal who dares to trespass on the elucidation of a geological problem is in much the same position, both are guilty of entering on ground which belongs to the Field or Practical geologist, who has examined the district and strata in question. Being of a practical turn of mind at present, I consider this apology necessary to geologists for the liberty here taken.

The southern portion of the Province of Manitoba is, according to United States and Canadian geologists, underlain by strata of Trenton age that is holding Trenton fossils which again is overlaid or capped by Cretaceous rocks. It has been proved by numerous drillings made in several parts of Ohio that the rock underlying a gas or oil producing region is Trenton limestone, over this is required a thickness of several hundred feet of strata so as to form a natural reservoir, as it were, to store or keep the oil and gas there generated, from such bituminous or animal remains as have been imbedded in what was once the bottom of

the Silurian sea, and now called the Trenton strata. The Cretaceous rocks form such a covering. The Manitoba limestone has not, however, the bituminous (oily or gaseous) shaley associations or look of the Trenton limestone, although the fossils, which by their presence and death there in ages past, are the cause or source of the gas or oil in the Trenton limestone are identical with those of the Manitoba limestone, this fact proves it to be of Trenton age. Is there or is there not an oil or gas producing area in Manitoba? By drilling through the Cretaceous strata till the Trenton is reached will the problem be solved. The question is one of such importance that its solution by a sufficient amount of drilling in Manitoba is a matter worthy of consideration. Here again is another matter for thought: ought not all Hydro Carbons, gaseous or fluid, as well as coal, lignite, soft, or anthracite be reserved in selling land to farmers? In what way can a farmer be entitled to receive as a gift a seam of salt, rock, or natural reserve of fuel 1,500 or 2,000 feet under his land, and of the existence of which he is ignorant? Salt or mineral springs may be reserved for health's sake, but the time once was when the salt of the earth was considered as valuable as the salt in the water. A very small royalty on such minerals would pay or compensate the Government for any outlay it might incur in the solution of questions such as this and possibly yield revenue, but more especially in a part where the liquidation of debt from Bonds would fluctuate any dryness there might be in the Provincial exchequer.

BRANDON.

The Gold and Silver Mining District Ouray County, Colorado.

Lennoxville, P.Q., 6th Oct., 1887.

The Editor

THE CANADIAN MINING REVIEW:

SIR,—Having just returned from the above named district I have pleasure in sending you a concise account of Ouray and the surrounding district as it may be of interest to some of your readers.

Now that the Denver and Rio Grande railroad is rapidly approaching this lovely mountain town of Ouray, it being only eight miles distant, its beauties will be made accessible to the travelling public. Ouray is the county seat of the county of the same name, and named after Ouray, Chief of the "Uncompahgre Utes"—or Indians. Uncompahgre means the "valley of Fountains," and in the town site of Ouray, and in the valleys below, there are numerous very large 'hot springs' which gush from the earth, and this fact is said to have given rise to the name.

Approaching Ouray by a well travelled toll road from the outer world, you pass through a level park traversed by the Uncompahgre river. It is about 10 miles in length and from one to one and a-half miles in width. At the lower end, close to the road, are some very large hot springs, the temperature of whose waters nearly reaches a boiling point, and are impregnated with iron, salt, lime and the alkalies. This park is bordered on the west side by a straight line of cliffs of sandstone, capped with volcanic rocks, gradually decreasing in height toward the north, and in the east by slopes more or less steep, from the "Uncompahgre Peak" group and its spurs. On either side of the road, as you drive through the park to Ouray, are flourishing farms, and the stream towards Ouray is well wooded with popular, pine, elder and willow.

Within about two miles of Ouray this park narrows into a magnificent gorge, bounded on the east side by precipitous cliffs of sandstone (of the lower Carboniferous formation), and sloping backward from the edge are dense forests of pine and aspen timber, the whole crowned by serriced peaks and truncated masses of grey trachyte, the summits of these peaks being from 3,000 feet to 4,000 feet above the valley, and from 10,000 feet to 14,000 feet above tide water. From this gorge you emerge into the beautiful amphitheatre in which stands the town of Ouray.

In the SW portion of the basin, in which stands the town, and where the waters of Cannon creek flow into those of the Uncompahgre, there are some lovely canons and picturesque gorges; and here, in places where the hot springs flow down over the banks into the main stream, the rocks are covered with a perfect mat of "maiden hair" and other ferns. A short distance from here, up Cannon creek, is a large cave, the floor and roof are covered with stalactites and stalagmites.

On the north side, and where you emerge from the gorge into the basin where stands the town, are almost perpendicular cliffs of the old red sandstone, these partially encircle the town, while around the other portion the hills are more sloping and covered with pine timber of various kinds. I estimate the average height, or rather thickness, of this sedimentary formation to be 800 feet; above this is the layer of trachyte or volcanic rock of an average thickness in this district of about 3000 feet to 5000 feet.

On the south of the town is a stratum of sandstone, and in the southwestern portion of the town limits, where are located several mines, the lodes have for their walls so-called quartzite, or really altered sandstone, their ores being contained in a gangue or matrix of quartz property. There is also here a stratum of ribbon jasper, also conglomerates in the shape of both pudding stone and breccia. The effect of heat in metamorphosing the sedimentary rocks is here shewn in a very marked manner.

Leaving Ouray at the south side, you ascend the picturesque and heavily wooded gorge of Canon Creek towards Sneffels and Virginus Basin, in which are located most of the celebrated mines of Sneffels district. About 3½ miles from town, and about 1,000 feet above it, you see the last of the red sandstone where the creek has cut through it, and you are now between walls of trachyte, the sheer bluffs on the east side stretching upwards in an almost perpendicular line for almost 1,000 feet. The west side is more broken and sloping. From this point of junction of the sedimentary and igneous rock to the summit of the highest peaks the trachyte prevails.

Professor Hayden, of the Geological Survey, claims this trachyte as No. 4, or the youngest of the four groups of trachyte rock. He says: "This group horizontally, is a restricted one, but fraught with occurrences of the highest interest. not only are the rocks themselves of very peculiar type for the position they occupy, but the presence of many metaliferous veins, lends additional importance to the group. Some of the highest mountains of the region are partly or wholly composed of it. The latest discoveries of ore-bearing veins seem to have been made at localities where the group occurs as merely capping the older ones. In other words instead of the vein being confined to No. 4, they extend through it, and can be reached in older formation." Speaking of these lodes, nearly all are found in trachyte No. 4. Sub-

sequent investigations have shown that they penetrate beyond the limits of this group, and without any appreciable change of course or character, enter the metamorphics which are covered by the trachytes. All the veins, located within the trachyte, which I had occasion to visit, were argentiferous, although it must be understood some of the lodes also carry gold.

South east of Ouray, is Red Mountain Park, which is distant about 10 miles. In this park, at the upper end, are some brilliant scarlet peaks. They are due to admixture of certain mineral substances, originally white, the presence of ferric oxygen compounds gradually changes this colour to yellow, red and brown.

The rock is a crystalline feldspathic paste of white colour, containing very minute transparent crystals of sanidite and small crystals of pyrite. Decomposition of pyrite releases the sulphur and changes the iron from a bi-sulphide to hydrates seaquioxide. This in varying percentages, produces the colours and shades above enumerated.

In writing of the mines, I must needs do so in a general and concise way, as were I to particularize each one that I have seen, it would fill an extremely big book. My object now is to give a general idea of the ores which came under my notice during my survey.

To begin.—In the Red Mountain Park district, on No. 3 Mountain, there are being actively worked a number of mines, varying in depth to 800 feet. In this district in some of the best paying mines, such as the "Yankee Girl," "Silver Bell," and others, the ore is found in what is locally termed "chimnies" or "shutes," but in reality are extinct craters of volcanoes, which prove in working to be very regular and persistent in their character. The walls are composed of porphyry and trachyte, and are from wall to wall about 20 feet in diameter. The ore is a mixture of "tenorite" or black oxide of copper, grey copper and stromeyerite, the latter carrying about \$16,000 to the ton of silver.

The "Yankee Girl" has one main shaft (bratticed) sunk to a depth of 800 feet. Eight levels are driven out 100 feet apart to intersect the "chimnies." The general equipment is very fine indeed, no expense having been spared. This mine has paid \$1,200,000 in the last two years, and its daily output is about 20 tons per day, which is (after the ore has been classified) shipped to the smelters.

The "Silver Bell" is another mine, lying about 1 mile NE of the "Yankee Girl mine." This has a (batticed) shaft sunk to a depth of 600 feet, with 6 levels running to the "chimney" in which the ore is found. The ore is a mixture of grey copper and galena, and runs about 200 ounces to the ton. The walls of the "chimney" are composed of porphyry and trachyte, and are well defined. The size of this "chimney" varies from 12 to 18 feet. The output is about 15 tons per day and is paying very big profits.

This particular district appears to be a volcanic centre, as the whole of the lodes in the outside districts seem to lead or converge towards this point, like the spokes of a wheel to the hub, I beg you will pardon the simile.

Outside mines in the fissure or lode form, are handsomely remunerative. Such mines as the "Virginus," "Ruby Trust," and others too numerous to mention, are being worked extensively, and are all well engineered and equipped.

In conclusion I would say that I regard this field as a most reliable one for investment of capital, and judging from the great influx of money which is pouring in, must, if judiciously

expended, place this district beyond rivalry on this continent.

I am, Sir, yours, etc.,

FRANCIS D. TAYLOR, M.E.

The following shipments of Canadian ore have been made from Montreal from 10th September to 3rd October, 1887:—

Date.	Shippers.	Ship.	Destination.	Tons.
Sept. 9	Lomer, Rohr & Co.	s.s. Earl King.	London	223
12	"	s.s. Khrweider	Hamburg	320
13	Wilson & Green.	s.s. L. Nepigon	Liverpool	246
16	"	s.s. Thorndale	London	318
16	Lomer, Rohr & Co.	do	do	225
17	Wilson & Green.	s.s. Thanemore	Liverpool	256
23	"	s.s. Oce'n King	London	359
24	Lomer, Rohr & Co.	s.s. Katie	do	230
24	Millar & Co.	do	do	535
30	Wilson & Green.	s.s. Canopus	Liverpool	398
Total....				3,110

A well known English authority has estimated the phosphatic manures used during last year as follows:—

England.....	500,000
Germany and Austria.....	800,000
France.....	250,000
United States.....	893,000

Tons of phosphatic manure employed, 2,443,000

The following patents have been issued by the Department of Crown Lands:—To Messrs. Wm. H. Fuller, of Ottawa, and Peter White, of Pembroke, for N^o 1 of lot 12, in 3rd range, Wakefield County, 100 acres as a phosphate mining location. Date of patent, 8th August, 1887. To Archibald Campbell, of Montreal, for lots 8 and 22 in 8th range, Denholm County, 272 acres as a phosphate mining location. Date of patent, 6th October, 1887.

The English market continues strong for 80 per cent. phosphate at a shilling per unit. with one-fifth penny rise, and enquiry is made for 75 per cent. at 10s. On the continent quotations are 13d. to 13½d. for 80 per cent. with one-fifth rise.

Rates from Montreal during the past month have been 7s. 6d. to London, and 4s. to 6s. 6d. for Liverpool. Large quantities could have been shipped at these rates as there was a scarcity of grain, but the low water in the Lièvre river prevented shippers from availing fully of the opportunities offered. Owing to the low freights for grain and deals one large steamer took phosphate for ballast and went to Norfolk, Va., to load cotton for Liverpool.

Kingston District.

A gentleman who has been successful in the iron mines of Lake Superior, has bonded or purchased several phosphate mines in the district north of Kingston, Ontario. He has also secured the refusal of several iron properties in the same region. It is supposed to be his intention to organize companies in the United States to work the properties that may be acquired.

Mr. John Foxton, of Sydenham, Ontario, has worked all the season upon a rich deposit of green phosphate, which, at a depth of seventy

feet from the surface, shows a width of several feet. All the drilling is done by steam and the hoisting by horse power.

The mines of Capt. Boyd Smith in Hinchinbroke and Bedford are producing a large quantity of phosphate, the bulk of which analyses 85 per cent. The deposits on this property are quite unique, being found in association with masses of magnetic iron. Seven distinct veins run for nearly a mile in a south-west and north-east direction, and contain on the surface either iron alone or iron and phosphate side by side. These seams when followed down sometimes turn wholly into phosphate and occasionally widen to a considerable extent. One pile of 300 tons is said to be composed of a larger average size of lumps than has ever been seen in Canada, showing that the deposits have been both extensive and pure.

Mr. James Bell has taken out a considerable amount of phosphate from his property near Lake Opinicon. Mr. Loishley, of Elgin, and Messrs. J. Smith & Co., of Sydenham, have also been producers this season. But with the exception of those mentioned before, no other persons have been shipping from the Kingston district. In past years the production of this region has mainly come from farmers, who were careless of the quality of their ore, and the low analyses obtained discouraged purchasers. By more attention to raising the grade, phosphate could be profitably mined in this section.

Perth District.

The Anglo-Canadian Phosphate Company, at the Otty Lake Mines in North Burgess, Ont., are sinking on a seam of phosphate in order to test the extent of the deposits at a depth. They are now down 100 feet and expect to sink another 100 feet before spring. Nearly three hundred openings have been made on phosphate on these properties and carried to depths of 20 to 30 feet. The seam now being worked has varied in width from one foot to seven feet of pure phosphate, besides several feet more of mixed phosphate and mica. If the seam is found to be large and pure at a greater depth it will support the supposition that many of the numerous openings will result similarly. As no deep mining has ever been done in this district, the experiment will be of great value and it successful will give encouragement for further operations.

Capt. Moore who has had a gang, of about 8 men prospecting on several lots here, has met with encouraging success. Some very large deposits have been uncovered. About 1,000 acres have been purchased, and offers have been made for several other locations.

Templeton District.

Messrs. McLaurin & Blackburn have made a division of the phosphate lands jointly owned by them, and the valuable mines in the 11th range of Templeton are now the property of Mr. Robert Blackburn, of New Edinburgh. The phosphate from these lots has gained the highest analyses ever obtained from Canadian phosphate in England and Germany, cargo lots this season having realized as high as 88 per cent. The mine is being timbered with reference to enlarged and economical methods of production. 1250 tons have been shipped during the present season.

Mr. Jackson Rae proposes to continue work, during the winter, in the deep shaft which has been sunk on a fine body of ore upon his lot in

the 10th range. The inclination of the shaft is so gradual that a skip railway is effectively used for hoisting the ore and rock.

The Canada Industrial Company have been working upon lots in the 10th range and have opened some good shows. They have erected substantial buildings and finished them with more taste than is usually displayed in mining regions. During the month bush fires have been very prevalent in this district, and they approached so close to this property that the buildings were for some time in imminent danger of being destroyed. As it was, several wooden outhouses were burnt to the ground.

Messrs. Gillespie, Paterson & Co., have been doing good work in the same locality, and have found some extensive seams. A small force is at present working in pit 2, from which the management state that about 150 tons have been mined this year. Nearly 250 tons have been mined from pit 1. Some negotiations have been made for the purchase of this property.
